LIST OF CONTRIBUTORS TO VOL. XXXVII.

Abbott, Dr. George E., New York.
Ackerman, Mr. G. K., New York.
Allen, Dr. Charles Lewis, New York.
Allen, Dr. Charles W., New York.
Angle, Dr. Edward H., St. Paul, Minn.
Archer, Dr. Harry Mortimer, New York.
Ashmead, Dr. Albert S., New York.
Ayer, Dr. A. D., Madison, Conn.
Ayers, Dr. Edward A., New York.

Backus, Dr. Ogden, Rochester, N. Y.
Baldwin, Dr. J. F., Columbus, O.
Baruch, Dr. Simon, New York.
Beach, Dr. H. H. S., Boston, Mass.
Berry, Dr. John C., Kioto, Japan.
Blair, Dr. Thomas S., Chambersburg, Pa.
Blanc, Dr. L., Aix-les-Bains, France.
Boldt, Dr. H. J., New York.
Boone, Dr. H. W., Shanghai, China.
Bosworth, Dr. F. H., New York.
Bowker, Dr. John C., Lawrence, Mass.
Brill, Dr. N. E., New York.
Brown, Dr. Daniel, New York.
Brown, Dr. George C., Gainesville, N. Y.
Brown, Dr. Sanger, Chicago, Ill.
Browning, Dr. A. G., Maysville, Ky.
Bryant, Dr. Joseph D., New York.
Bulkley, Dr. L. Duncan, New York.
Bull, Dr. William T., New York.
Burnett, Dr. Swan M., Washington, D. C.
Burt, Dr. Stephen Smith, New York.
Bushong, Dr. Charles H., New York.

Canfield, Dr. Ralph M., Derby Line, Vt.
Carhart, Dr. J. W., Lampasas, Tex.
Carmichael, Dr. T. H., Philadelphia, Pa.
Castle, Dr. F. A., New York.
Chapin, Dr. Henry Dwight, New York.
Chappel, Dr. W. F., New York.
Cheesman, Dr. William S., Auburn, N. Y.
Claiborne, Dr. John Herbert, New York.
Coe, Dr. Henry C., New York.
Coleman, Dr. H. Waldburg, Trenton, N. J.
Collins, Dr. Moses, Lakeland, Ky.
Corning, Dr. J. Leonard, New York.
Crampton, Dr. Henry E., New York.
Crandall, Dr. R. Percy, U. S. Navy.
Currier, Dr. Charles G., New York.

Dana, Dr. Charles L., New York.

THE RELATION BETWEEN PERIPHERAL IRRITATION AND NERVOUS PHENOMENA, WITH SPECIAL REFERENCE TO EYE-STRAIN.[1]

BY M. ALLEN STARR, M.D., PH.D.,

CLINICAL PROFESSOR OF NERVOUS DISEASES, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

THE question of the exact relation between peripheral irritation and serious nervous phenomena is not a new one, but has been brought into prominence of late by those who have paid some attention to the study of eye-strain. It is maintained by these recent writers that irritation arises from a lack of balance between the various ocular muscles, and is sufficient to produce serious general nervous manifestations, and even such diseases as epilepsy and chorea. Observations of greater or less degree of reliability have been published in the medical press in support of this statement. And the theories which are propounded upon the basis of these observations gain in interest, because of their direct application to the treatment of nervous affections. In consequence, the advantages of treatment directed to the eye alone in serious nervous diseases are being urged on all sides.

The enthusiasm of the exponents of this method equals that displayed in former years by others who have worked along the same lines. For the supposed importance of peripheral irritation in the production of nervous diseases is not a new proposition. It has been the subject of discussion before. Genital irritation was urged at one time by a distinguished surgeon as a cause of paralysis of the legs, and for a time circumcision was regarded as a preliminary procedure indispensable in the treatment of many nervous diseases, among which infantile paralysis and spastic paraplegia may be named. Later, the influence of congenital stricture of the urethra was brought forward as a cause of many neuroses and of temporary states of nervous excitability. And not long after, the claims of the genital organs of women rose in the estimation of the profession as fertile sources of nervous disease. Recently it has been taught that the peripheral irritation of nasal obstruction is responsible for many respiratory neuroses, of which asthma may be taken as a type, while the ear and its canals, and even the teeth, have not been neglected by those in search of hidden seats of disease. Intestinal irritation by worms, and rectal irritation from fissures and fistulæ, may also be mentioned. But to refer to other sources of peripheral irritation would simply be to enumerate the various organs of the body. It is not strange, therefore, that to the trend of modern fashion certain ophthalmologists should have yielded; and that inasmuch as the exact relation between internal eye-strain and nervous symptoms had long been ascertained, they should have fallen upon external eye-strain as the sole remaining *point d'appui*.

The object of this glance at past investigations is very largely intended, not to throw ridicule on them, but to emphasize the fact, which cannot be denied, that, though each form of peripheral irritation may produce nervous symptoms, no one form has such a special importance as to warrant the extravagant statements made by its earliest supporters. It has been the history of progress in every line of medical research which has been repeated in this particular: First, extravagant assertion, based on hypothesis; then impotent opposition and negation; lastly, calm, judicial conclusion that truth lies in neither extreme.

Let us look, for a moment, at the present position of the profession on the question of phimosis as a cause of nervous disease. It is no longer thought to be a possible cause of true paralysis, either infantile paralysis or spastic paraplegia. It undoubtedly may be a cause of nocturnal incontinence in young children. It is rarely considered as a cause of convulsive disorders. Occasionally a case will be seen in which an irritation arising from the penis is unquestioned. The child has pain on micturition, handles the organ frequently, and suffers from pain when erection occurs. The prepuce is found to be contracted or adherent, or to have beneath it a hard, irritant mass. After this condition has been present for some time, slight spasmodic seizures may appear; or nervous manifestations of a mental kind, irritability of temper, and bursts of rage. The existence of local irritation is known and observed by the parents as well as by the physician, and circumcision cures the nervous symptoms. I have seen only four such cases in the past five years; I have not seen more, though I have records of 3,500 cases of nervous disease. Such cases are not very common—and they are quite characteristic in their form. If the nervous phenomena are mental, they are intermittent; they are not like well-known forms of mental disease, they are rather evidences of extreme irritability of temper than of actual insanity. There is no such thing as intermittent mania occurring in attacks of a few minutes, and followed by perfect sanity without other symptoms. If the nervous manifestations are convulsive, the attacks are again quite different from true epilepsy in their mode of development. It is the rule that such attacks are quite numerous from their very commencement. In one case of my own the child had as many as ten attacks daily within a week of the onset, and sixty attacks daily of slight convulsive seizure resembling *petit mal*, with staggering. In the meantime he was unusually restless and uneasy within one month of the onset. And the importance of this rapid onset of the symptoms cannot be too much exaggerated. For the great variety in the true epileptic seizure makes a diagnosis between reflex convulsions and true epilepsy, from the study of the attack alone, impossible; although I think that in a reflex attack a total loss of consciousness and biting of the tongue are rare, and a subsequent stupor is also rare. But it may be stated with confidence that idiopathic epilepsy develops in a different manner; attacks being at first very far apart, then more and more frequent, but very rarely reaching the frequency of once in two weeks within five years of their commencement. I think it may therefore be safely stated that when genital irritation is a cause of nervous disease in childhood there is evidence of local disease which attracts attention, and the nervous symptoms resulting are characteristic in the rapidity of onset. The same may be truly said of reflex convulsions occurring during teething, or arising from the intestinal irritation of worms. When congenital stricture of the urethra is the source from which irritation arises, some difficulty in micturition, some pain on erection or in intercourse, some local signs of a disorder of the organs is the rule. When these are absent, in a case of nervous

[1] Read before the Section on Neurology, Academy of Medicine, December 13, 1889.

disease, the question of the existence of a stricture near the meatus rarely presents itself to the mind. In other words, when peripheral irritation is the true source of nervous symptoms, nature points to that source by pain or discomfort in the irritated part.

I do not desire to open the question of the possible effects of diseases of the female genital organs in producing nervous symptoms. These were discussed here a year ago by Dr. Peckham. I desire, however, to call attention to the fact that such an operation as cauterization of the clitoris for epilepsy—a well-known form of treatment pursued many years ago, with some apparent success, in England by one man, and not without its defenders at the time upon the Continent—would now be considered malpractice. And I think it may be safely stated that fewer ovariotomies are performed to-day, with a view to the cure of epilepsy, or even of serious forms of hysteria, than were performed ten years ago. Yet this is the epoch of ovariotomy—and the operation is now considered a safer one than ever before. Time has shown that the statements of early enthusiasts have not been substantiated. Personally, I may say that I have seen not a few cases of epilepsy associated with ovarian disease, the attacks being preceded with an aura of pain in the ovarian region, which have *not* been permanently benefited by the removal of the diseased ovaries, and I am quite sure that my experience has been that of other observers.

Dr. William Goodell, of Philadelphia, has recently said: "By a very large number of practitioners, even by specialists working in other fields of medicine, these organs" (the uterus and ovaries) "are too often wrongfully made the scapegoat for headaches and nape-aches, for spine-aches and backaches, for weakness of vision, for aural disturbances, for sore throat and weak lungs, for irritable heart, and also for a host of so-called uterine symptoms. Yet these very symptoms may be due wholly to nerve exhaustion or malnutrition of nerve-centres, and not to reflex action or to direct action from some real or supposed uterine disorder. . . . The abuse of uterine treatment through mistaken diagnosis is, in my opinion, the great medical error of the day" (*Medical News*, December 7, 1889).

It is perhaps too early to make very judicial statements concerning the effect of irritation on the nasal cavity. I have seen in a small boy a case of distinct attacks of great mental irritability, quite similar to those which have been observed during genital irritation, which were apparently due to an hypertrophy of the so-called pharyngeal tonsil, and which ceased when this obstruction to respiration was removed. This boy also suffered from gradually increasing deafness due to the same cause, which was also cured by the operation, and which attracted attention to the seat of irritation. But when the very large number of patients with similar obstruction is considered—obstruction arising from deformities of the nasal septum, from hypertrophy of the turbinated bones, from polypi in the nose, and from other causes, and the great rarity of general nervous symptoms, especially of epileptiform attacks or of chorea in these patients—I think it may be concluded that nasal irritation is a comparatively rare cause of nervous disease, and only acts as a cause in persons of nervous constitution; and in support of this I can refer to the chapter on reflex symptoms in Dr. Bosworth's recent treatise.

Coming now, at last, to the subject of eye-strain, is it not reasonable to believe *à priori*, and judging by analogy, that its importance as a factor in the causation of nervous symptoms has been greatly exaggerated? Let us look at a few facts. Many persons have slight degrees of myopia, hypermetropia, or astigmatism which never attract notice and go for years without producing any apparent inconvenience. If the degree of these defects is more than insignificant, at the age when the eyes begin to be used for reading there appear some symptoms. Either complaint is made of defective vision directly, or slight nervous symptoms, such as headache, appear to follow the continued use of the eyes, with such uniformity that the connection of the symptoms and their cause is evident to the lay mind. There are a few cases recorded in which, in nervous persons, the eye-strain may cause not only headache and smarting and pain in the eyes, but even slight reflex movements of the eyes, such as convulsive winking, or twitching of the head and neck. Two such cases have come under my observation within a year, both of which were materially relieved by the correction of hypermetropia with astigmatism, by Dr. Webster. It will certainly be admitted by all that such errors need to be looked for and corrected. Yet, if the very large percentage of the population who wear glasses is considered, and the very small number of these who have experienced any serious nervous symptoms, such as spasmodic twitching, prior to obtaining glasses, the relative infrequency of severe nervous symptoms, such as chorea, being produced by eye-strain becomes at once evident. I think it may safely be stated that, out of one hundred patients who apply to ophthalmologists to be fitted with glasses, ninety apply because vision is noticed to be defective, or because of such symptoms as headache and vertigo, and not more than ten because of the existence of serious nervous symptoms; and it is well known that those whose vision is defective go, as a rule, directly to opticians, and do not consult a physician at all.

I am not aware that any authority has ever advanced the statement that internal eye-strain is a cause of such serious nervous manifestations as epileptiform attacks. That it is a cause of chorea has been distinctly disproven some years ago by Dr. C. S. Bull. And this fact is to be borne in mind when the question of the influence of external eye-strain is discussed.

Before proceeding, however, to that discussion, let me call attention to a very important fact which has been elicited by a consideration of the various forms of peripheral irritation thus far considered. It is this: That whenever a source of irritation exists, nature points to it by producing sensations of discomfort; and this discomfort is felt in almost every case in the part in which the irritation exists. The eyes, if overstrained, are felt to be weak; the nose, if obstructed, is known to be obstructed because breathing through the mouth becomes habitual, or is produced by the slightest catarrh, and is often noisy; the ovarian symptoms, especially pain, appear before or with the nervous symptoms; the genital irritation is manifested by discomfort which, in those too young to tell of it, leads to handling the organs; the worms lead to fecal impaction, or diarrhœa. We know that pain is only a means of warning and protection offered by nature; a natural sign-post pointed to the physician's door. In pleurisy it insures the immobility of the chest; in sciatica it secures the rest of the limb; in acute rheumatism it prevents motion of the joints. Discomfort is a minor degree of pain, and may be taken similarly as a warning. The fatigue after undue exertion, the exhaustion after mental effort, the malaise of disease, cannot be misinterpreted. Nature is a very safe guide, and is a prompt and efficient adviser.

When peripheral irritation exists sufficient in degree to be in any way injurious, it may be stated, as a rule to which there are only occasional exceptions, that nature points it out by producing a sense of discomfort or of pain in the part irritated.

With these preliminary facts in mind, let us consider the proposition advanced within the past few years, that insufficiency of the ocular muscles is a frequent cause of functional nervous diseases, such as epilepsy and chorea. Certain questions arise in this connection, and require an answer.

1. Are insufficiencies of ocular muscles common?

Anyone familiar with muscular physiology knows that muscular power varies constantly. Effort weakens it when long continued. Rest increases it if moderate in duration. Effort strengthens it when moderate. Too long a rest is followed by atrophy. Thus the daily expe-

rience of life tends to show that the muscular condition varies constantly. And anyone who will test the power of his grasp on a dynamometer three times each morning and evening for a month will be surprised at the variation which is observed.

The smaller the muscle the greater the relative degree of variation. Now, during the past three years I have been constantly testing ocular muscles as to their power, and I have observed, under the same tests in the same individual, at different times, considerable variation. I am sure that practice in overcoming prisms, in learning how to use the muscles voluntarily, is one source of apparent variation. Without using the term "insufficiency," it may be safely stated that the actual power of the ocular muscles varies considerably from time to time. And my observations lead me to believe that there is some relation between the general condition of a patient and the power of these muscles. Neurasthenic patients vary greatly, at times showing relative weakness of different muscles, at times showing none. And when the same patient is tested in different stages of the complaint, muscles at one time weak may be found at other times to be strong, and *vice versa*. And as these patients recover under treatment the general strength and proper balance of their muscles return. What is true of neurasthenic patients is also true of others suffering from functional diseases, such as chorea, epilepsy, migraine, neuralgia. And when, as in epilepsy, the disease is one which directly involves in the attack the ocular muscles, the variation in their equilibrium before and after an attack is often very evident to the tests.

I think it may therefore be said that in normal individuals, and in those affected by functional diseases, the power of the ocular muscles varies considerably from time to time. This does not, however, imply any causal relation to the general condition of the patient.

2. Does a real strain of one or more ocular muscles produce discomfort?

Those who have done much testing with prisms will, I think, admit that continued effort on the part of one or more of the ocular muscles very soon elicits complaint by the patient. Patients very soon acquire the power to so converge or to so diverge the eyes as to overcome the effect of a prism, in looking at an object twenty feet away. Prisms of three or four degrees are easily overcome by the external rectus. Prisms of eight or ten degrees are usually easily overcome by the internal rectus. And I have rarely elicited complaints from patients when the tests were short and stopped here. When, however, stronger prisms were used, and the tests repeated three or four times, the patients would say that the eyes felt strained; or the eyes would begin to water and the patients would be inclined to rub them. In a word, a real strain of an ocular muscle produces discomfort.

3. Do the majority of people with slight ocular insufficiency suffer discomfort?

It is my experience that in the majority of patients with either functional or organic disease who have normal vision, or whose vision has been made normal by glasses, little attention is paid to the eyes. Such patients, if questioned, will say that their eyes are all right. This, of course, should not exempt them from an ophthalmoscopic examination. But if the attention of a neurasthenic or hysterical person is called to the eyes, he may, even when without any actual defect, either of vision or of his muscles, begin to complain of his eyes. It is my experience that unless an extreme degree of ocular insufficiency exists patients do not suffer discomfort. It is also my experience that in functional neuroses of any kind the moment a patient's attention is directed to an organ he becomes conscious of sensations in that organ which may be perfectly natural and yet which he believes to be abnormal. Spontaneous testimony is therefore more valuable than suggested testimony. And from spontaneous testimony I am led to conclude that slight ocular insufficiency, varying from time to time as it naturally does, even in neurasthenic individuals who are extremely sensitive to all discomfort, does not produce discomfort.

In view of the facts already established, that variations in the muscular power are natural and that nature warns us of overexertion in any direction by means of conscious fatigue, it becomes evident that an insufficiency of an ocular muscle incapable of causing discomfort is really a matter of very little importance.

4. May ocular insufficiency produce nervous manifestations?

The review of the subject of peripheral irritation in general has shown that any peripheral irritation of serious nature or long continuance is capable of producing nervous manifestations; and that such irritation, by giving rise to discomfort or pain, is indicated by nature as the cause of the symptoms. I have cited cases of genital, ovarian, and pharyngeal irritation from my own experience. I can also cite a case of true nervous manifestations undoubtedly caused by eye-strain; but it is the only case of the kind which I have seen in the past three years, after a large number of careful examinations. A girl of nervous parentage was found to be suffering from general nervous irritability of a marked kind. She had slight twitchings of her facial muscles, head, and neck, occasional headaches, hyper-excitability of all muscles to percussion, with increase of tendon reflexes, no symptoms of organic disease, but a history of hysterical attacks, occurring at intervals for ten years, occasional motor weakness, and great mental irritability at times, and inability to read and study continuously. All these symptoms were markedly aggravated by any continuous use of the eyes, which soon became blurred and heavy either on reading or on looking at objects at a distance. The power of abduction in the external recti was only five degrees and there was an insufficiency of four degrees of these muscles at twenty feet, while the examination with prisms at once produced the same feelings of discomfort of which she at other times complained. Here was a case, then, in which an insufficiency of considerable degree was present; producing discomfort when the weak muscles were used, and leading, in my opinion, to the nervous excitability and mental irritation to which she was predisposed by her nervous constitution. I therefore referred the case at once to an ophthalmologist for treatment, and received from him a confirmation of my view of the case. I do not know the result.

It is probable that everyone of much experience could duplicate this case; and it proves to me, as such cases have proved to others, that serious muscular insufficiency of the ocular muscles may cause nervous manifestations in a nervous person. But I repeat that in my experience such cases are rare. I have seen but one in three thousand cases of nervous disease.

5. Are such nervous manifestations characteristic?

It has been a matter of dispute whether so-called reflex disturbances are identical with serious nervous diseases—such, for example, as hysteria, chorea, and epilepsy. When any one of these three diseases is studied it becomes evident that a very wide difference is observed in the symptoms of patients suffering from the same affection. The varieties of epileptic attacks are innumerable. The distribution and severity of choreic movements is very various. The forms of hysteria cannot be recorded. To affirm, therefore, that nervous manifestations do or do not belong to one or the other of these diseases by studying the phenomena alone would be impossible. But each of these diseases in turn has a typical course and a general character. And it seems to me that in their course—in their mode and period of appearance, in the frequency of the occurrence of symptoms, in the variation in relation to influences acting upon the patient—the nervous manifestations arising from peripheral irritation are characteristic. So that they need not be identified with the symptoms of these diseases.

I have already alluded to the difference between true insanity, true epilepsy, and reflex neuroses. In regard to

chorea, it seems to me that in true chorea the onset of the motions is more rapid, their situation more definite (general or unilateral, rarely local), the history of infection or fright more decided, and the accompanying anæmia and cardiac complications more uniform than in any of the forms of reflex neurosis which simulate it. It is also natural to believe that the reflex cases readily become chronic unless the cause is removed, and do not yield to arsenical treatment, while in true chorea the influence of this treatment is usually evident by the time physiological effects are produced, and relapses rather than chronicity are the rule. Out of one hundred and twenty cases of chorea of which I have records, but four have been unaffected by arsenic and have become chronic.

It seems to me, therefore, that the nervous manifestations arising from peripheral irritation, when carefully studied, differ from the ordinary neuroses in their history and therefore present features which are characteristic. Reflex neuroses should therefore not be called epilepsy and chorea, even though they may resemble these diseases.

6. Are cases of neuroses due to peripheral irritation common?

This is not to be decided hastily or by any one observer. The specialist is too prone to find his own notions exemplified in his patients. And this question can only be answered by a consensus of opinion. A discussion of this is therefore requested, that numerous opinions may be obtained. In the mass of nervous cases there are doubtless quite a number whose symptoms are reflex in origin. But when the records of other specialists are inquired into, it becomes evident that each observer, working on his particular organ of the body, observes many cases of extreme peripheral irritation in that organ which do not present any nervous phenomena. My impression therefore is that a true reflex neurosis is comparatively rare in relation to the number of patients suffering from peripheral irritation, and also in relation to the number of patients suffering from chorea, epilepsy, and hysteria. If this is so, the question arises whether there is not some hereditary or acquired nervous irritable weakness in the patients thus suffering which must be taken into the account in estimating the cause of their disease and which cannot be reached in treatment by the mere removal of peripheral irritation.

I think it may be safely stated that serious irritations of genital, ovarian, intestinal, nasal, and auditory origin are not very frequently observed in our nervous patients. Hence analogy would suggest that irritations from the eye are equally infrequent, whether of a kind to cause internal or external eye-strain.

The conclusion, therefore, which seems inevitable is that while eye-strain or other peripheral irritation may be an occasional source of nervous manifestations, such as discomfort, headache, nervousness, or, possibly, local twitching of eyes and neck, it is a rare cause of nervous disease, and that the symptoms which it may produce are not to be identified with serious nervous diseases such as epilepsy and chorea. I would class eye-strain either from muscular insufficiency or from errors of refraction with other kinds of peripheral irritation neither more nor less frequent and important. I consider it necessary to ascertain in any case of nervous disease whether any form of peripheral irritation is present. But unless it is serious and has produced discomfort which has been spontaneously observed by the patient, I should not attach much importance to its presence as an etiological factor unless the nervous manifestations were of such a character and mode of development as to point to a peripheral origin. I do not believe that true epilepsy or chorea can be produced by eye-strain or cured by its relief. I am constantly seeing cases in which such treatment has been faithfully pursued and has failed. And I think that the general indiscriminate recommendation of treatment directed to the relief of supposed eye-strain in these diseases will soon come to be recognized as malpractice.

THE AURICULO-VENTRICULAR (PRESYSTOLIC) SOUND. SOME CONSIDERATIONS ON CARDIAC DISEASE IN EARLY LIFE.[1]

By HENRY DWIGHT CHAPIN, A.M., M.D.,

PROFESSOR OF DISEASES OF CHILDREN AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, AND AT THE WOMAN'S MEDICAL COLLEGE OF THE NEW YORK INFIRMARY; ATTENDING PHYSICIAN TO THE DEMILT DISPENSARY.

I. THE AURICULO-VENTRICULAR (PRESYSTOLIC) SOUND.—The presystolic, auriculo-systolic, or auriculo-ventricular murmur has been a subject of much discussion and acrid controversy. Gendrin in 1841 called attention to a presystolic murmur, and Fauvel in 1843 considered it to be due to mitral obstruction. This view seems to have been accepted at the time, but some years later Dr. Barclay advanced the idea that a mitral obstructive murmur had no existence in fact, the sound usually attributed to this condition being really due to regurgitation. This dispute has recently been renewed in the columns of *The Lancet* (1887) by Dr. Dickinson, who denies that the so-called presystolic murmur is indicative of mitral stenosis. He regards the murmur as covering the first portion of the systole up to the point of closure of the valve, and names it rather an early systolic murmur. Gairdner, Balfour, Bristowe, and others have vigorously replied. Dr. Bristowe has summed up the arguments in favor of the presystolic nature of the murmur as follows: (1) It accords with the physiological fact of the auricular contraction running into the ventricular systole, the beginning of which is indicated by the very sound that terminates the murmur; (2) the murmur precedes the pulse, and ends with the apex-beat; (3) the presystolic murmur does not differ in quality from the earlier mitral murmurs which are acknowledged to be direct; (4) all the direct mitral murmurs are characterized by consonatal noisiness and lack of penetrating power, and are audible over a curiously restricted area, but are not conveyed into the axilla, as all regurgitant murmurs are. Finally, post-mortem examination not infrequently reveals a condition of stenosis of the mitral valve. The conclusions of this paper are derived from clinical studies alone, and hence must be taken for what they are worth. A presystolic or auriculo-ventricular sound is produced by some interference with the normal and easy passage of blood through the auriculo-ventricular septum or valve. The murmur is rough in quality, beginning at the end of diastole and ending abruptly with the systole. In rhythm, it may hence be considered post-diastolic as well as presystolic. One of the most characteristic points about this murmur is its abrupt termination. This quick stop of the abnormal bruit is very different from the gradual ending of mitral regurgitation. All the authorities I have been able to consult consider that the presystolic murmur is invariably due to organic disease at the mitral valve. There is a class of cases, however, in which this sound is distinctly heard, that I believe are entirely free from organic heart disease. Reference is here made to growing children, especially girls, who are pale and hydræmic, and suffer from various digestive disturbances. These cases are not only subject to palpitation of the heart, but, at times, especially after exercise, a more or less rough presystolic murmur may be heard at the apex. Many of these children have been confined for a long time in crowded or badly ventilated school-rooms. Possibly they are over-ambitious in their studies, but, at any rate, are in a condition of defective nervous equilibrium. Under treatment by iron, cod-liver oil, nutritious and easily digested food, with plenty of fresh air, the abnormal heart-sound will often disappear. It has seemed to me that the trouble in these cases is due to an irregular muscular action, dependent upon a defective innervation of the heart. Weak children have an especial tendency to a faulty, over-irritable action of the muscles, both voluntary and involuntary. This may be shown only by incontinence of urine, or by

[1] Read before the Section on Practice of Medicine, New York Academy of Medicine, November, 1889.

twitching of certain muscles of the face, or it may eventuate in general chorea. Why may not the innervation of the heart be affected, with or without any of the disturbances just mentioned? In such a case an irritable, strongly acting auricle, with a mitral valve whose muscular fasciculi are too tense, might be a cause of a blubbering sound just before the systole. The sound produced by any such irregular muscular action would be intensified by the watery condition of the blood.

Undoubtedly a large proportion of cases of the presystolic murmur are due to organic valvular trouble. I have histories of forty cases, that I have been able to keep under observation for different intervals of time, varying from a few weeks to several years. The longest case has been eight years, during which time not a single cardiac symptom has been manifested. My youngest case was two years; next, 1 at seven, 4 at eight, 4 at nine, 2 at ten, 5 at eleven, 4 at twelve, 4 at thirteen, 6 at fourteen, 2 at fifteen, 2 at sixteen years, and 5 at later periods of life. I believe this murmur is exceedingly frequent in early life. My observation is based upon a much larger number of cases than those just quoted, which, of course, are too few for generalization. Meigs and Pepper state that mitral obstruction is comparatively frequent in childhood. Goodheart considers that in very young children this lesion is almost unknown, but begins to be noted in children of eight or nine years, and after this becomes common as years advance, until, finally, it is one of the commonest affections of adult life. Eustace Smith, on the contrary, considers that stenosis of the mitral orifice, unaccompanied by insufficiency of the valve, is not common in the child.

In 31 of my cases there was simple mitral obstruction, while in 9 cases there were combined murmurs. Of the latter, 5 were double mitral, 3 were double aortic and double mitral, and 1 was a combined mitral and pulmonic obstructive murmur. The negative symptoms so frequently accompanying slight degrees of mitral obstruction doubtless lead many physicians to occasionally overlook the murmur. The commonest symptoms that I have noted are varying degrees of pain, and dyspnœa on exertion. The pain is usually referred directly to the region of the heart. In 16 of the cases of simple mitral obstruction pain was an important symptom. Upon running upstairs, or any similar violent exercise that caused a rapid action of the heart, this pain would ensue with more or less severity. It seemed as if the laboring of the heart to pass the blood quickly through the partially constricted auriculo-ventricular septum must produce a neuralgia in some of the adjacent nerves. Dyspnœa was very rarely severe, but in a large proportion of cases it was noticeable upon exertion, both by patient and family. A slight, dry cough was more or less frequent, and bronchitis was readily contracted and not very amenable to treatment. In the absence of marked symptoms, referable directly to the circulatory and respiratory organs, we must frequently look rather to the general condition of the child to observe the effects of mitral obstruction. An imperfect nutrition and absence of vigorous growth may not infrequently be the sole apparent result of imperfect cardiac function in early life. Most of my cases showed a lack of vigorous vitality, and a poor nutrition. I believe a careful examination of the heart will explain a certain proportion of cases of obscure developmental trouble and poor vitality in children, that cannot otherwise be accounted for.

The connection of this murmur with rheumatism is an interesting subject for consideration. Out of 31 cases of mitral obstruction, 20 presented evidences of rheumatic taint, as follows: In 6 cases there was a history of rheumatism in the immediate family, but none in the patient; in 4 cases there was rheumatism in the family, and the child had likewise been attacked, while 10 cases gave a history of rheumatism only in the patient examined. Of the combined murmurs, 3 had had rheumatism, and 1 chorea but no rheumatism. It is now well known that the symptoms of rheumatism in early life are milder and in every way less pronounced than in the same affection of later years. There is frequently no appreciable redness or swelling of any joint. Rheumatic pains, however, go from one joint to another, or from one set of muscles to another, existing independently of any such factors as injury or over-exercise, which must be eliminated before making a diagnosis. In using all the care possible, there will be a certain class of cases in which it is exceedingly difficult to say whether obscure wandering pains are rheumatic or not. A careful examination of the heart may sometimes convince us that some uncertain pains have really been due to a rheumatic taint. Most of my cases of mitral obstruction have been preceded by a rheumatic manifestation that has been mild even for children. In this respect I can confirm the observation of Sansom that mitral stenosis is not independent of rheumatism, but is associated with the less pronounced forms of it—with its insidious, and not, so to speak, with its explosive varieties. He quotes the records of the London Hospital for 1880, which showed, while only fifty-eight per cent. of the cases of mitral stenosis presented a history of rheumatism, that seventy-seven per cent. of the cases of mitral regurgitation were rheumatic. The same author considers that an endocarditis, sometimes accompanying a rheumatism without pronounced phenomena, may be manifested by no subjective symptom, and yet differ in no essential feature from that which occurs in obvious relation with rheumatism. "The endocarditis which results in mitral regurgitation is more violent, so to speak, whilst that which initiates stenosis is more protracted, giving rise to a slower formation of fibrous, quasi-cicatricial tissue that under the even pressure of blood in the auricle tends to form the smooth septum which has erroneously suggested a possible congenital causation." In 1886 I read before this Academy the conclusions based upon a study of 76 cases of rheumatism in children, of which 26 had valvular disease of the heart. Of these 26 cases, 18 had mitral regurgitant murmurs, while only 4 presented evidences of mitral obstruction, combined in 3 cases with other murmurs. These murmurs, however, were only considered in reference to cases in which the history of rheumatism was undoubted, being tabulated in connection with studies in rheumatism. I find, on the contrary, that when studying 31 cases of uncombined mitral stenosis, in 17 cases the vague pains were sufficiently repeated and suspicious to warrant my ascribing them to a rheumatic taint. Sajous (1888) quotes the opinion of Duroziez, Landouzy, and Schnell in favor of the frequent idiopathic origin of mitral stenosis, and, when pure and simple, it is found almost exclusively in women and children. In two cases, I have thought the presystolic murmur could be explained by aortic regurgitation, the mitral curtains being floated out by the return current and hence producing an obstruction to the mitral direct current, as explained by Flint. Goodheart advances an idea which, while difficult to prove, appears somewhat plausible. He queries whether the mitral regurgitation of infancy and early childhood, when recognized and carefully tended, may not in time eventuate in mitral stenosis. The mitral inflammation, which at its outset produced incompetence, by contraction and cicatrization may culminate in a final contraction of the orifice.

In making a diagnosis of the mitral direct murmur, it is well to remember that it varies according to the action of the heart. Walshe states that he has known the murmur to come and go from day to day, probably from a varying force of the heart's action, in a case where the mitral orifice was very greatly contracted and rigid. Sansom says most observers will agree that in some cases the presystolic murmur is extremely variable; it may be inaudible during repose, and yet very evident when the patient is made to manifest some slight exertion. It is my custom to have the patient jump up and down in a vigorous manner before auscultation in any suspected

case. Two of my patients with undoubted mitral stenosis have been accepted as first-class risks by insurance examiners, who, I think, would have given a different report had they taken this precaution. When the heart is acting quietly, not only may this murmur be indistinct, but the accentuation of the pulmonic second sound is not so noticeable. In some cases, by gently pressing the hand over the heart, a rolling, vermicular action is noticed, due to the slight delay and resistance to the passage of blood from auricle to ventricle. The well-known "purring thrill" can usually be distinctly noted. The existence of præcordial pain and dyspnœa on exertion will afford corroborative aids to diagnosis.

If we regard the prognosis of mitral stenosis from a theoretical stand-point, it will not be good, owing to the comparatively limited compensation that is possible. As a matter of fact, however, I believe the prognosis to be favorable. A large proportion of the cases will present very few grave symptoms, and some none at all. A very loud presystolic murmur exists in a young man, twenty-five years of age, whom I have watched for the past eight years. During this time he has not had a symptom that would appear to be referable to this lesion, although he plays tennis and engages in other active sports. I believe this form of valvular trouble is most apt to be overlooked; doubtless many persons who are not suspected of cardiac disease have some degree of mitral stenosis. The only instances of death I have known have had regurgitation combined with the stenosis, but most of my cases have been in early life, when death from any form of cardiac disease is not common. One boy, seven years of age, with marked cyanosis from birth, bulbous fingers, intense dyspnœa, pain over the heart, expectoration of blood, and blue mucous membranes, was evidently suffering from a congenital lesion of the heart, the only physical sign of which was a mitral obstructive murmur. Such cases are rare, and the prognosis is, of course, very bad. If we can follow a case of mitral stenosis for a reasonable length of time and observe that the action of the heart is not embarrassed, and the patient suffers from little or no inconvenience, I believe the prognosis to be exceedingly good, even although the murmur persists. Treatment of any kind may be unnecessary. The use of general hygienic measures, with an occasional tonic, will sometimes be required. Some oversight should be kept over these cases and the indications met as they arise, just as in any other form of cardiac trouble.

II. Some Considerations on Cardiac Disease in Early Life.—It is frequently the experience of physicians to be called upon to treat cases of valvular disease of the heart, when it is impossible to trace back to the inception of the disease. The patient may not be able to give a history either of rheumatism or endocarditis, and seeks advice for dyspnœa, swelling of the extremities, or other symptoms of failing circulation. I believe a large proportion of the cases of valvular disease in the adult have begun in childhood. The first beginning of the trouble, which is the period for hopeful treatment, is not recognized. The nature of the rheumatism that attacks children is often obscure, and several attacks of wandering or so-called "growing pains" may be overlooked. While the heart may be the first structure attacked by rheumatism, this is not the common order of events. In most of the histories of valvular disease in children that I have taken, the cardiac affection seemed to come on after several attacks of rheumatism. Great care should be exercised to make an early diagnosis, and vigorous measures be taken to combat the first manifestations of rheumatism in children, fearful that, although the heart may escape the first mild attacks, it may suddenly and unexpectedly become affected by an equally light manifestation of the disease. When endocarditis ensues, the symptoms are apt to be very obscure. Palpitation, slight pain, and breathlessness, with a dry cough, may not be particularly noticed by parents, although the child seems sicker than before. These cases are brought to the dispensaries, and the mother is quite surprised to learn that her child has beginning heart disease. Just at this juncture rest is indicated above all things. If this is not procured, the delicate, softened heart-muscle quickly undergoes dilatation, followed by permanent damage to the valves. Dilatation very readily takes place in the young subject. Compensation, however, quickly and completely ensues from hypertrophy, and there may be no sign, until years later, that great damage has been effected. But can no effort be made to avoid permanent lesion? By recognizing the endocarditis at the start, and keeping the child quiet, in bed if possible, we may seek to avoid dilatation and consecutive crippling of the valves. I have recently had a case under observation showing how this may sometimes be accomplished. A child, three years of age, was sent to the Babies' Ward, complaining of pains in his knees and ankles, with a slight cough, much dyspnœa, and distressed look in his countenance. He breathed with a good deal of distress, and auscultation revealed a loud systolic bruit. There was some swelling of the joints, but the rheumatism yielded to treatment, leaving a mitral systolic murmur, heard at the apex and transmitted around to the angle of the scapula. Great effort was made to keep the child quiet, with every facility in the way of nurses, amusement, and good discipline. He spent most of his time semi-reclining in a steamer-chair. At the end of a month the murmur was distinct but not so loud, and when two months had elapsed it had entirely disappeared. If it is true that endocarditis will not always nor necessarily eventuate in valvular disease, it is certainly a clear indication to do all in our power to avoid dilatation, and hence increase the chances of such a desirable result. After the immediate symptoms of endocarditis have passed, children are too often allowed to play about and take part in all kinds of vigorous exercises, as if nothing amiss had happened.

The perfect compensation usually occurring in childhood prevents many of the symptoms of circulatory disturbance seen in later life. Their vascular system is likewise healthy and elastic, which facilitates the work of the heart. As patients grow older, vascular changes ensue, which increase the strain upon a heart already crippled. I watched a boy for five years, having a double aortic and double mitral murmur, with great hypertrophy, who never appeared in the least incommoded by these grave lesions. He died from drowning while trying to swim against a swift current. In many of these cases, however, there is a faulty nutrition with more or less profound anæmia. The patients must be kept under observation, and the blood maintained in a good condition by a generous diet, iron, and cod-liver oil. We may hope in some cases, where the lesion is not extensive, that with an improved condition of the blood and healthy growth the heart may recover itself. Eustace Smith states that heart murmurs in children not uncommonly disappear; not only recent, soft murmurs, such as are heard in cases of chorea or acute rheumatism, but also louder and harsher murmurs, which are known to be of longer duration. If there is no hypertrophy of the left ventricle, it is not probable that any serious valvular defect is present.

27 West Fifty-first Street.

Voice Lozenge.—Dr. Hinkle recommends the following formula as the best for a "voice lozenge" in the ordinary hoarseness of singers and speakers. A small piece should be allowed to dissolve in the mouth just before using the voice:

Cubebs	½ grain.
Benzoic acid	½ "
Hydrochlorate of cocaine	¼ "
Powdered tragacanth	½ "
Extract of liquorice	5 grains.
Sugar	13 "
Eucalyptol	½ minim
Oil of anise	½ "

Black currant paste, enough to make 20 grains.

—*Chemist and Druggist.*

WHAT REAL VALUE HAVE NATURAL MINERAL WATERS IN THE TREATMENT OF DISEASES OF THE SKIN.[1]

By L. DUNCAN BULKLEY, A.M., M.D.,

PHYSICIAN TO THE NEW YORK SKIN AND CANCER HOSPITAL, ETC.

POPULAR impressions and verdicts have always a certain measure of fact and reason for their base, however far from exact truth they may be, and however exaggerated may be the deductions therefrom. In no practical line is this exemplified more strongly than in regard to the use of natural mineral waters in drinking and bathing for diseases of the skin.

It would seem most natural and proper that nature's remedy, supplied so bountifully in many and diverse portions of the earth, should be effective in relieving the ills of mankind; and what class of affections would be more naturally benefited by it than those of the skin? Some of these are known and popularly recognized to be local and contagious, and might be reasonably supposed to be curable by proper baths; while others are regarded as constitutional, and therefore should be benefited by the internal use of nature's remedy, which, being taken into the system, must act in some way to wash out or "purify the blood." The logic is natural and conclusive, and, as we know, has some measure of basis on facts.

Therefore, from the earliest times we find that the various medicinal springs of the world have been resorted to by multitudes, suffering from many different diseases, and we know that the impression has become exceedingly prevalent, both among the laity and the medical profession, that mineral waters, used both in bathing and drinking, are "very good for diseases of the skin." It cannot be denied, moreover, that a certain proportion, although it is small, of the great number of persons afflicted with cutaneous affections, may and do receive more or less benefit by the proper employment of this form of medication. But, on the other hand, anyone who has seen much of dermatological practice must have experienced disappointment time and again in the results obtained, or not obtained, from visits to mineral springs by patients who had made the trial either on his advice or on the recommendations of others; furthermore, the time and money which have been wasted, and often worse than wasted, by thousands of sufferers seeking relief in this direction can hardly be imagined, while the bitter disappointments endured in these fruitless and expensive experiments by those who have been lured on by laudatory circulars and advertisements would be heartrending to relate.

What, then, is the cause of the numberless failures to get relief from this supposed valuable means of treatment, and what, if any, is the solution of the difficulty? Is it a delusion to suppose that there are virtues in the medicated waters which nature provides with such a lavish hand in all quarters of the globe? or does the fault lie only in our failure to apply them scientifically and successfully?

The subject of the various mineral springs which may at times be of service, and their proper use in diseases of the skin, is a very large one, and cannot, of course, be compassed in an essay such as the present. But it has occurred to me that a brief presentation of some of the aspects of the case might open the subject for discussion, and might, perhaps, result in a more intelligent and consequently more successful employment of some, at least, of those waters which are better known.

It is needless in this presence to speak of the necessity for accurate diagnosis, and the intelligent direction of the proper disease to the special water, for all here recognize that only thus can any satisfactory results be possibly attained. For a patient with some affection of the skin to wander aimlessly to one and another mineral spring, at the suggestion of friends or those unacquainted with his special malady, and to use the waters according to the dictates of whim or fashion, is as useless or harmful as for one to enter a drug store and act in a similar manner. Definite and correct ideas must, therefore, prevail in regard to the relative and peculiar value of various springs and classes of springs in different affections, and to this end more reliable data must be collected and utilized than now exist, before we can speak as confidently as we could desire in regard to the probable advantage to be derived in many skin affections from the use of mineral waters. It behooves all of us to collect facts bearing in the direction of the effect of mineral waters in diseases of the skin, for mutual aid, and for that of the public; for most of the information now accessible on the subject comes directly or indirectly from those more or less interested, financially or otherwise, in one or another special spring. The history of the rise and decline in popularity of some springs, such for instance as the Missisquoi, once celebrated for cancer, would be an interesting chapter to write, were it not that it would be the sad record of the blighted hopes and wasted funds of thousands, who travelled long distances only to find the promised cure even farther off than before.

A certain amount of benefit comes to many individuals, and to their diseases, whatever they may be, from a visit to and sojourn at a great variety of mineral springs; this benefit and improvement is often attributed to the water alone, when that is but one of many elements contributing to the result. Hope and faith are, without question, elements which unconsciously enter into the actual result obtained under any plan of treatment; the influence of the mind on the body has been proven in many ways and accepted, especially since the subject has been so well worked out by Tuke, and this element operates largely in many cases when trips are made to mineral springs on the assurance of friends or physicians that benefit will result.

But there are also a number of other elements to be taken into consideration, as contributing to any improvement attending treatment at mineral springs, which should never be forgotten. Change of air and climate are often of themselves productive of much good, while the change of scene, rest from ordinary occupations, and the energy given to effect a cure, often contribute not a little to the good result; and, finally, an altered dietary may also be an element of importance.

An additional reason, accounting, in part, for the greater improvement often resulting from visits to mineral springs abroad than follows treatment at those in this country (which may be similar, and of even greater real value), is found in the more intelligent use of the waters at the former, and the stricter obedience to the directions of physicians there; they also are apt to prescribe more rigid modes of life, and more regular and systematic use of the waters, than is often the case in this country. At most of the springs abroad there are resident physicians, who have, in many cases, spent years in the study and use of the mineral waters, and are consequently quite able to prescribe them in a manner to produce the best possible results. Whereas in this country, with few exceptions, the springs are not so provided with medical advisors, or, very frequently, if there is a resident physician he is a novice, who in reality has relatively little practical knowledge of the use of the particular water under consideration. It has also been my experience to find that very many patients who have visited mineral springs in this country have employed the waters without accurate medical directions; indeed, most of them never consult any physician in the place, but use the waters either according to some plan of their own, or as recommended by friends, or they follow the custom of the spring, guided by the attendants who have charge of the baths or drinking fountains. Could anything be more crude and ill-advised? and need we be surprised that the wonderful

[1] Read before the American Dermatological Society, at the thirteenth annual meeting, Newport, September 18, 1889.

combinations of remedies, compounded in the bowels of the earth, should not be found more efficacious than they commonly are in relieving human sickness and suffering? There is certainly need for more accurate knowledge of the properties and effects of our mineral springs, and of the manner in which the best results can be obtained, that we may give specific directions, if we would secure the best results attainable. For many years I have endeavored to visit some of the springs of this country or Europe each summer, to observe their practical workings, and I make it a practice to lay out the course of treatment for my patients who visit them, either from personal knowledge or from that obtained from reliable sources; which course is to be followed unless otherwise directed by some physician consulted at the spring.

Still another element calculated to disturb our judgment as to the real value of mineral springs in the treatment of diseases of the skin, is found in the character of the adjuvant treatment by drugs, often given at the same time, either by the physicians at the springs or taken independently. A striking illustration of this is found in the well-known heroic treatment constantly employed for syphilis at the Hot Springs of Arkansas, Aix-la-Chapelle, and other places. There are few, if any, of us, who do not believe that, if the same courses of treatment, or better ones, were as diligently followed elsewhere away from the springs, with an equally free use of common water in drinking and bathing, together with a correct and even mode of life, and the avoidance of stimulants, there are few, I say, who have experience in this line, who do not believe that many, if not all the cases would do equally well, or better, and at a very much less expenditure of time and money.

But in spite of all the negative, or even antagonistic, considerations which have been mentioned, all of us must acknowledge that mineral springs are of service in a certain small proportion of cases, and may at times, if properly employed, prove of much service in conjunction with other measures in the management of diseases of the skin.

Without now entering upon the varieties of mineral waters, whether hot or cold, neutral, saline, alkaline, calcic, purgative, or containing ingredients supposed to be specially active, such as lithia, sulphur, iron, alum, arsenic, bromine, iodine, chlorine, etc., and their special applications, let us first briefly consider some general points in connection with the subject, relating to their *modus operandi*, in order to see in what manner we might reasonably expect them to be of service in diseases of the skin.

It is a little difficult to distinguish the effects of waters taken internally and those used in bathing, where both are employed; but for the purpose of study we will consider first rather the internal effects, referring later to those to be expected from bathing.

It is first to be noticed that we find the same water acting very differently in different persons, even with the same diseases, and also, that we frequently find the same disease benefited by the use of various mineral waters of quite diverse characters. Indeed, it is often the practice for patients to try one mineral spring after another, until one is found which is of special service—or, as is more commonly the case, until they find that all fail to give relief—when the patient is often at last more benefited, or cured, by intelligent and adequate medical skill secured elsewhere.

There is one ingredient which belongs to all medicinal springs, namely, the water itself, which contains the mineral ingredients, and this is the element which, in reality, contributes most to the cure. This is shown to be true by the results often following hydropathic treatment of various kinds, where the water employed is not supposed to be medicinal, but simply the ordinary, pure water used for household purposes. It is also seen in the well-recognized beneficial effects often following the free use of plain hot water taken internally, as has been practised so freely of late years that it has become almost a fashion. The same results are seen to follow visits to such springs as the Poland and Bethesda, which are known to be simply very pure and entirely neutral waters, and in which no mineral constituents are claimed. So that in estimating the effects of a mineral water, we must recognize that the increased amount of fluid taken by the patient is a very important element in the case, and if a visit to some springs will result in the washing out of the system by a freer flow of water through the emunctories, we could readily expect benefit in a certain class of cases characterized by sluggish bowel, kidney, or skin action.

The mineral ingredients undoubtedly contribute somewhat to the result in many cases, but, as remarked before, the variety of springs which are oftentimes serviceable in the same disease is so great, that it is very difficult to determine just which ingredient contributes most to the result. From some waters there is, of course, a pronounced bowel action; others act more freely on the kidneys; many seem only valuable in reference to their alkalinizing action on the blood; others, such as Carlsbad and Vichy, appear to have a specific action on the liver; few seem to have marked action on the skin as an organ, and we all must agree that very few have been proved to have any very decided curative effects on diseased skin.

I know that this last statement may excite some criticism, especially from those interested in certain special springs, and may be at variance with the statements published in various circulars of places of resort; but from a very considerable experience, both with large numbers of patients who have been to various springs, and from personal visits to many spas in this country and abroad, I am forced to state my conviction, or rather conclusion, that a very large share of mineral waters fail to confirm the hopes raised, and rarely cure conditions which are not remediable by ordinary, or extraordinary, medical treatment.

It may here be remarked, however, that it is not always, or often, possible to judge of the anticipated action of a mineral water from the chemical analysis commonly furnished, although some knowledge of its virtues may be thus learned. There is undoubtedly some additional effect produced by the compound as it is furnished fresh from nature's laboratory, and the combination of its many ingredients, which is different from that obtained from the same ingredients when artificially prepared; also, mineral waters act somewhat differently when taken fresh as they issue from the ground, with the nascent sulphurous or carbonic acid gases contained, than they do when preserved and transported long distances. A striking illustration of the difference between natural waters, as employed at the spring and when used elsewhere, is found in Vichy water; this is largely used for bathing at the spring, and is drank also warm or hot, as it issues from the ground, but elsewhere it is almost universally drank cold, and even with ice; Carlsbad, Kissingen, and other waters are also used hot at the springs, but generally cold elsewhere.

What are the benefits to be derived from those mineral waters containing special ingredients, so often lauded for the cure of diseases of the skin? such are those containing lithia, iron, sulphur, alum, arsenic, bromine, iodine, chlorine, etc.? I fear that others will only echo my experience, that in practice they are found so often to fail that no great dependence is to be placed on them. Where these ingredients are specially indicated by the condition of any particular patient, they may do a measure of good to an eruption, but either the dosage is too small and uncertain, or the treatment is carried out for too brief a time in many cases, or, for some reason or other, careful medical observation finds that in a large share of cases the results generally obtained are unsatisfactory, or at least the record is negative.

Iron springs undoubtedly serve an excellent purpose in many cases, and color and strength are often obtained from such springs as Schwalbach and Pyrmont abroad, and the Red Spring at Saratoga and the Oak Orchard Acid Springs; and undoubtedly in certain cases some cutaneous lesions, dependent upon debility, will improve, or even disappear under their use.

Waters containing arsenic have been supposed to be of special service in diseases of the skin, but I have not found, however, the benefit from them, especially those of Bourboule, which I had hoped; I cannot speak from much personal experience in regard to those containing bromine, iodine, or chlorine. In certain cases of eczema, exhibiting an especially marked catarrhal type, the Rockbridge alum water seems to exert a decidedly beneficial effect.

But the mineral waters which are popularly credited with being of the greatest value in skin affections are those containing sulphur in greater or less quantity; of these Richfield, Sharon, Avon, and the Virginia White Sulphur may be taken as the types in this country, and Aix-la-Chapelle and Barèges as representative ones abroad. All of us must have seen dozens of cases with various eruptions who have tried these in vain, and I doubt if many have been seen who had received much or very permanent benefit from them. This need not surprise us, for all recognize how very little effect sulphur, taken internally, has on this class of affections, in spite of popular impression to the contrary. Where there is a rheumatic element back of the cutaneous disease these sulphur springs effect some amelioration, but in a large share of cases it is safe to say that the results produced are largely those obtained by the amount of water passing through the system, and by the alkaline salts contained in the water—the sulphur counting for little or nothing.

While the internal use of mineral waters does not appear to yield the results hoped for in diseases of the skin, the free and proper external employment of some of them, combined often with their more or less free internal use, will sometimes prove efficient aids in the management of some forms of cutaneous disease.

A certain number of cutaneous lesions are local in character, in others a local element preponderates over the internal cause, while in most, if not all, instances there is a greater or less derangement of the action of the skin as an organ; all of these conditions may be benefited by local treatment, and in many of them the proper use of bathing commonly plays an important part. It would, therefore, seem likely that the proper mineral water, rightly used, would be of service—and so it is found to be, occasionally.

But here again, as commonly employed, we are met with the difficulty that the mineral waters are so frequently used without discretion, both as to the particular spring visited and the variety and stage of the disease treated; we also find great errors committed in regard to the frequency, mode, and duration of bathing, together with the proper after-treatment of the skin, both as to drying and friction, and also adjuvant measures. How necessary do we all find it that the minutiæ of directions should be most carefully carried out, in order to effect the best results with local treatment in diseases of the skin; and yet, as commonly practised, the bathing at health-resorts is often or generally performed in a routine and crude manner, while little or no attention is given to the suitability of the process to particular cases. How frequently do we find harm even done by a vigorous course of bathing, as administered at some mineral springs. If we would get favorable results, this class of remedy must be more intelligently employed, and that can only be obtained by personal attention, with knowledge of the springs employed. So that in the external use of mineral waters, no less than in their internal administration, there is no high-road to their universal employment; to be of service they must be prescribed and used accurately, as are other remedial agents.

While patients with almost any affection of the skin may at times seek relief at mineral springs, there are comparatively few diseases which are practically found among those frequenting them. These may be named, in the order of their probable frequency at the springs, as follows: Eczema, psoriasis, syphilis, acne, chronic urticaria, lichen planus, lupus, scabies, ichthyosis, pruritus, and prurigo.

The great mass of those seeking relief are undoubtedly eczema patients. And I think I see less benefit to this disease from the indiscriminate use of mineral waters, and, on the other hand, more benefit from their judicious and properly regulated employment, than in any other affection of the skin; but in very many of these patients this plan of treatment forms but a very small, and often insignificant, part in the entire management of the complaint, and that commonly toward the close of the case.

By far the larger part of cases of eczema receive most benefit from alkaline and moderately purgative mineral waters, early in the season, followed by a tonic spring for a short period later. Vichy, or Marienbad, or Ems, abroad, for three to six weeks, followed by two or three weeks at Schwalbach, or Royat, will often accomplish considerable for cases of chronic eczema. Carlsbad is sometimes required when there is much abdominal plethora. In this country I make considerable use of the White Sulphur Spring, followed by the Old Sweet, in Virginia, or I employ the laxative water of Saratoga, with the Red Spring later. In very chronic cases, with gouty elements, the Hot Springs of Virginia serve a good purpose. Harrowgate, in England, occasionally proves very effective. But in eczema great care must be exercised lest the spring treatment excites acute eruption, for some of my worst cases of general eczema have been those evidently produced by a course of treatment at a medicinal spring; under its use a small amount of chronic eruption has been lighted up into a general and most severe eczema, covering a very large surface.

Psoriasis, as we know, is a most rebellious disease, and mineral waters have comparatively little permanent effect upon it, although in many cases they serve an excellent temporary purpose, and are sometimes even of some lasting value. The sulphur waters yield the best results, and occasionally the arsenical water of Bourboule, used at the spring in bathing as well as drinking, will accomplish much. The Hot Springs of Virginia or Arkansas seem to have little if any effect on the disease. In many cases of psoriasis free sea-bathing will prove far more beneficial than the treatment of any mineral spring.

Patients with syphilis frequently visit mineral springs, but, as we all know, with little if any benefit, unless active medical treatment is carried on at the same time. The subject has been already alluded to.

Acne will often be benefited very considerably by visits at proper mineral springs, though in a large share of instances, as ordinarily employed, these are of very little value. The sulphur waters seem to have relatively little good effect, except as they may act as purgatives and serve to increase the urinary secretions. The iron springs are more commonly of service, also mildly alkaline springs, which affect favorably the digestive organs, such as the Allegheny Springs in the Cumberland Mountains, Missisquoi Springs in Vermont, and Poland Springs in Maine.

I will not take further time to speak of other less common affections, for which mineral waters may be of more or less service, as it would be difficult, indeed, within the limits of a short paper to do the matter justice. The general subject touched upon is a very large one, and I do not think to have at all compassed it, much less to have presented any proportion of the facts possible, concerning the real value of mineral waters in diseases of the skin.

The object of this paper, as before stated, is rather to elicit discussion and to open the way at a future time, perhaps, for a more elaborate consideration of the subject; for it is one in which we all, as the curers of disease, should have the greatest interest, but one which I do not recollect to have seen considered in this manner in print.

I have called attention to the fact that mineral waters, whether used internally or externally, or combined, are able in but relatively few instances to cure diseases of the skin; what, then, are their real value in the practice of

dermatology? I will answer briefly, that in a not inconsiderable proportion of cases they may, if used wisely, afford us a greater or less assistance as adjuvants, mainly at a season of the year when our patients are apt to be away from our personal supervision more or less, in order to seek change of scene and air in the pursuit of health and happiness. During these summer vacations our patients not infrequently, from fancy, fashion, or folly, go to places and localities, and indulge in pleasures and occupations which act prejudicially, and to a greater or less degree undo the good already obtained by previous treatment; or it often happens that during this period they often neglect the routine of treatment which they had previously followed, and suffer proportionately therefrom.

It is, therefore, at this time that proper treatment at mineral springs will often come to our aid, and, if judiciously selected and faithfully carried out, this means of cure adds its mite, little or great, to what we have already accomplished; for this reason I have thought it best, at the present time, to direct your attention to the subject which has been thus imperfectly considered.

Clinical Department.

AN EARLY CASE OF INFLUENZA.

By JULIUS SOLOWEITSCHYK, M.D.,

NEW YORK.

The case which I have to report first came under my care on December 5th, but as there were no similar cases in the same house or in the neighborhood I did not regard it as one of epidemic disease, and in consequence did not report it to the Board of Health. At the time that the first suspicious cases were reported my patient was so far on the road to convalescence that the characteristic symptoms had disappeared. Now that the patient is well, as I look back and observe with care the entire course of the disease, it seems worthy of a report.

I was called to see Frank S—— for the first time on December 5, 1889. According to his own account he had then been ill and confined to his bed for three days. He had a severe cough with profuse expectoration, the glottis and parts about were swollen and painful on motion, and the mucous membrane of the mouth and nose was inflamed and swollen. The tongue was white and thickly coated and the sense of taste was completely abolished. The voice was hoarse and nasal in tone. There were very tender spots on both sides of the chest, but the pain seemed to be muscular. Headache and lassitude were complained of. The temperature was 101° F., and the pulse 100. I ordered an expectorant and antipyrin. On the following day all the symptoms were more marked, the inflammation was higher, the cough more severe, and the expectoration more profuse. There were no physical signs pointing to any trouble in the lungs. The patient complained of nausea and great prostration, and was very despondent. He was unable to open his mouth well on account of the inflammation and swelling of the mucous membrane. In addition to the other remedies I then ordered an ice-bag to the throat and cracked ice to be swallowed. I gave him also a gargle of permanganate of potash and a liniment for the soreness of his chest. The following day the pain in the chest and the cough were better, but the pulse was still 100 and weak, and the temperature was 101°. The patient complained of a very severe pain in the region of the acromio-clavicular joint, which was found to be muscular and which disappeared upon the application of massage. On the same day I noticed ulcerated spots on both sides of the posterior molar teeth and also an ulcer on the right border of the tongue. Painting the mucous membrane with a mixture of borax one part, and glycerine five parts, and an application of deodorized iodoform to the ulcers gave great relief. On December 9th, the seventh day of the disease, the patient was much better and began to improve steadily from this time.

To recapitulate briefly, we had here well-marked and severe laryngitis, tracheitis, stomatitis, and rhinitis, moderate fever, various muscular pains, prostration, and mental depression, all of which taken together are, I think, sufficiently characteristic of influenza. On the seventh day the symptoms began to subside, but complete recovery was not established until the twenty-first day.

AN EXPERIENCE WITH THE INFLUENZA.

By RAMON GUITERAS, M.D.,

PHYSICIAN TO THE NEW YORK DISPENSARY.

As one of the physicians of the New York Dispensary, and having in that capacity seen a large number of cases of influenza, it has occurred to me that a short account of my experience with the disease might be interesting to the readers of the Medical Record. The institution to which I refer has exceptional opportunities for the study of all diseases on a large scale, situated as it is in a very populous district, which is largely inhabited by the laboring and pauper classes.

The course of the epidemic at this Dispensary has been a very interesting one to study. My class is one of unclassified Italians, which averages generally about 30 daily, 10 new and 20 old, patients. Since the "grip" has introduced itself, the number has increased from between 60 to 70 daily. Of these, almost 40 cases are new patients, of whom fifty per cent. are suffering from *la grippe*, and twenty per cent. of the old cases are suffering from the same trouble. I have had, since Christmas alone to December 30th, 100 cases of the disease occurring in men, women, and children, ranging from two to fifty years of age, although, probably, ninety per cent. of them have been between the ages of twenty to forty. Of these cases, eighty-five per cent. have been males, principally strong and robust Italian laborers, who have been obliged to put up the shovel and the pick and succumb to the popular malady. These all complain of the same symptoms, chilly sensations or chills followed by high fever, loss of appetite, general prostration, feeling of weakness, especially in legs, strong frontal headache, general rheumatic pains, but especially in the chest and back, foul and coated tongue, bad taste in the mouth, constipation, etc., perhaps nasal catarrh, but at all events winding up in almost every case in a dry bronchitis lasting from two days to two weeks, the feeling of weakness and sweating on slight exertion occurring during this same period.

In reviewing these cases and considering them collectively, I find that only about ten per cent. of the cases have had any nasal catarrh to speak of. That about two per cent. have suffered from an intestinal form of the disease having the same general symptoms as the others, with the exception that the catarrhal symptoms of stomach and intestines have been most marked, and have shown themselves in vomiting and diarrhœa; severe frontal headaches seem to occur in all cases. Pains, variously described as in bones and muscular (probably muscular in most cases), were complained of in about forty per cent. of the cases, although I think that they all suffered from them in a more or less marked degree. Pains in orbits and eyeballs, spoken of by many as characteristic, were only marked in about ten per cent. of the cases coming under my observation.

The epidemic which had been threatening, so to speak, for two weeks past, was finally showered down upon us as a Christmas gift, is at present date at its height, and will continue in all probability for another week and will then begin to decline, so that one month hence the "grip" will be a thing of the past.

The experience in the rooms of the Dispensary is the same, Dr. Cutler's class in general medicine being very large, about 75 cases a day, 50 new and 25 old. Of these,

about sixty-five per cent. of the new cases and twenty-five per cent. of the old ones are suffering from the disease. Dr. Hance's experience in the same class is about the same as Dr. Cutler's. The district work, for which two physicians are employed, is heavier than ever before, averaging about as many daily as it formerly did weekly, so that the force has been increased. This is all due to the epidemic, fifty per cent. of the cases being those of influenza; so that over a hundred cases daily are treated at the Dispensary. In all these cases recovery took place, and, as far as I can ascertain, there were no complications. The treatment instituted may be summed up as follows:

If the attack occurs in the morning a mild cathartic is administered, generally calomel in from two- to ten-grain doses. This is followed at night by a ten-grain Dover's powder and ten grains of quinine. On the following day, when the catarrhal symptons become marked, a pill of morphine (gr. $\frac{1}{10}$), ext. bellad. (gr. $\frac{1}{3}$), camph. (gr. $\frac{1}{2}$), and quin. (two to three grs.), is given every three or four hours.

When the bronchitis is the prominent feature, a mild expectorant mixture is given, containing syr. licorice, squills, senega, chloride of ammonia, morphine, etc. For frontal headache antipyrin, ten to fifteen grains, with whiskey, is administered.

OPERATION UNDER HYPNOTISM.

By EDWARD L. WOOD, M.D.,

RESIDENT SURGEON ST. BARNABAS HOSPITAL, MINNEAPOLIS, MINN.

THROUGH the courtesy of Dr. Hugo Toll, of Minneapolis, Minn., I am enabled to relate the following case which, occurring in his private practice, still came under my personal observation, as the patient, at the time of operation, occupied a bed in our surgical ward. A. S., male, aged seventeen, Scandinavian, entered hospital September 8th, with osteo-myelitis in the upper third of the humerus. There was considerable pain and swelling, some redness, partial immobility of shoulder and elbow-joints, and three fistular openings, one directly in the axilla, one slightly above the insertion of the deltoid, and the third higher up the arm and more posteriorly situated than the last one. In the three days preceding the operation the patient was hypnotized six times by Dr. Toll, in order to get him under good control. On the morning of September 9th he was hypnotized in his bed, and then led to the operating-room and caused to lie upon the table. The several fistulæ were then explored, scraped out, and washed out, after which an incision four inches long was made on the outer aspect of the upper third of the arm, to the bone, and an opening three inches long and three-fourths of an inch wide chiselled to the medullary canal with considerable difficulty on account of the osteo-sclerosis.

I do not intend to give the technique of the operation, nor the clinical history of the case. The work was done under thorough antiseptic precautions. One fistula connected with the incision, and into the other two drainage-tubes were inserted, the recent wound packed with iodoform gauze, and dressings applied with great ease, as the patient, while still cataleptic, could turn from side to side, move about, or sit up, as we directed him.

At 9.50 A.M. he was led to his bed, and told that at twelve o'clock he could sit up and have something to eat, the nurses, meanwhile, being cautioned not to disturb him.

He lay perfectly quiet until that time, and at twelve o'clock, sharp, sat up in bed, stretched his well arm, and said, "Dr. Toll said I could have something to eat at twelve o'clock."

Amputation above the elbow would certainly not have been more painful than this operation, yet the hypnotic condition was preserved through it all, with a loss to the operator of not more than a minute and a half, all told. I have seen several minor operations done with the patient in a cataleptic condition, but to me this case was a revelation, as I think it will be to many of my fellow-practitioners, throwing, as it does, a little light upon what it is possible to do with a favorable subject.

Progress of Medical Science.

Treatment of Barber's Itch.—Dr. Rosenthal orders the seat of the affection to be closely shaved daily, and the following ointment to be rubbed in twice a day:

℞ Acid. tannic ..... grs. xlv.
Lact. sulph. ..... ʒ jss.
Zinc. oxid.,
Amyl ..... āā ʒ iv.
Vaselini ..... ʒ j.
M. Sig.: To be used twice daily.

In a month nothing remains of the eruption but a very slowly disappearing erythema.

Professor Mosetig-Moorhof recommends, in the *Wien. Med. Presse*, the following emulsion for chronic cystitis:

℞ Iodoform. ..... ʒ ij.
Glycerin. ..... ♏ ijss.
Aq. dest. ..... ʒ iij.
Gum tragacanth ..... gr. iv.

Half an ounce of this emulsion is suspended in a pint of warm water. This is injected into the bladder, which has previously been washed out with plain warm water. The process is repeated every three days. After three or four applications the cystitis is said to be cured, or at least very much improved.—*Provi. Medical Journal.*

The Disinfection of Intestinal Discharges.—In the intestinal evacuations of typhus, dysenteric, and cholera patients, Professor Uffelmann instituted a considerable number of experiments with various substances, with the following results: 1. Equal parts of sulphuric acid and water. Certain destruction of all germs after two hours. 2. Sulphuric acid 1 part, to 2 parts of water. Destruction of all germs after six hours. 3. Hydrochloric acid and water, equal volumes. Destruction of all germs after twelve hours. 4. Hydrochloric acid 1, to water 2. Almost certain destruction of all germs after twelve, and certain destruction after fourteen, hours. 5. Carbolic acid. After one hour numerous colonies continued to develop, as also individual typhus colonies; after twenty-four hours, greatly isolated, and no typhus, colonies. 6. Creolin in 12.6 per cent. emulsion. After twenty-four hours, individual colonies continued to develop, but none of typhus or of cholera bacilli. 7. Potash lye with water, equal parts. After acting for an hour, individual colonies continued to grow; none after six hours. 8. Caustic lime, 0.2 gramme, and fæces. After one hour, and even after twenty-four hours, numerous colonies continued to grow, also several of the typhus bacillus; none of the cholera bacillus. Caustic lime, 0.2 gramme, and fæces. Individual colonies continued to grow after twenty-four hours—none, however, containing the typhus or the cholera bacillus. Milk of lime, one hundred and twenty per cent., 12½ parts to 1 part of fæces. Destroyed the Eberth bacillus within two hours. 9. Non-acid sublimate solution, 2 per 1,000. After acting for a quarter of an hour, a tolerably large number of colonies continued to grow; isolated colonies with the typhus, but not the cholera bacillus. After one-half hour, fewer than after one-fourth hour. After twenty-four hours, very few or no colonies, and none with the typhus or cholera bacillus. 10. Solution of sublimate, acidulated with hydrochloric acid, 2 to 1,000. Many less colonies developed than after addition of the unacidulated solution. After one-quarter hour, only isolated colonies observed; none of the typhus or cholera bacillus, and after twenty-four hours, as a rule, none at all. 11. Boiling water. Even when 8 parts of boiling water were added to 1 part of fæces, it did not always disinfect.—*The Medical Age.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, January 4, 1890.

THE EPIDEMIC OF INFLUENZA.

THERE is now no doubt that influenza, or what is popularly known as "the grip," has become epidemic in this city and is scattered broadcast over the country. It is also quite evident that its general characters correspond with those noted in connection with the prevailing type of the malady in Russia, Germany, and France. Fortunately it is of such a mild type that, save for its invasion of large districts and for the large numbers of persons attacked, it would scarcely be noticed in the category of ailments connected with the usual ones which occur during winter months, associated with rapid and varied changes of temperature and humidity.

The type of the present epidemic partakes more of the febrile and nervous variety than that of the purely catarrhal. The increased temperature in the beginning of the attack, with the severe pains in the head, back, and lower extremities, are the leading phenomena which are noted in the large majority of cases. Only in a comparatively few instances are the coryzal symptoms the leading features of the seizure. This latter is, perhaps, a fortunate circumstance, in view of the generally accepted opinion concerning the greatly exaggerated danger of bronchitis and pneumonia as necessary complications. The prostration is oftentimes extreme, but by no means dangerous, and readily yields to the usual remedies.

The period of illness is comparatively brief, and rarely is the ordinarily robust patient confined to his room more than two or three days, very many, indeed, keeping up and about from the beginning to the end of the sickness.

The reports of the fatality of the disease, as might have been expected, have been very much exaggerated. Particularly does this remark apply to the alarming reports of the recent death-rate in Paris. In point of fact, there is no disease with such a wide prevalence which has such a comparatively low mortality. In this country, at least, there is yet to be reported the first case of death which can be laid to a pure and simple attack of the disease. Even the serious complications are so few as scarcely to merit recognition alongside of those which are constantly occurring with the usual diseases of the season.

The after-effects of the epidemic will doubtless be marked by feelings of prostration more or less continued, and a lowering of the health-tone. The previously robust will quickly rally, while the feeble will require stimulants and tonics for variable periods. The contagiousness of the malady has not declared itself, thus corresponding with the general character of the disease as noticed in previous epidemics.

The treatment has been in accordance with indications, and has necessarily varied. The remedies which have found most favor are laxatives, anodynes, antipyretics, and tonics, with stimulating expectorants. For the headache antipyrin and the bromides have held their reputation; calomel and salines as the laxatives have many advocates; while quinine in tonic doses, especially in the latter stages, has the confidence of the majority.

From present indications, and from past history, the epidemic is likely soon to pass over, a few days more settling the question of immunity from attack.

With this epidemic, as with all others of its kind, the feeble and old have been the first to succumb and the slowest to recover, although all classes of cases have quite generally suffered. There is no better protection against an attack than the maintenance of good health by avoidance of over-fatigue, of undue exposure, and of insufficient food and sleep. But even these conditions are not absolute safeguards, as no one living in an invaded district can have his safety guaranteed. In all probability there will be very few indeed who, after the epidemic shall have passed away, will claim a full immunity from any of its influences, or who will not be somewhat the worse for an entirely unsought experience.

MEDICINE AND THE CIVIL SERVICE.

THE letters of Dr. Dawbarn and our other correspondents regarding the competitive examinations of the Civil Service have excited considerable interest and comment. All who have read this correspondence will, we think, agree that while Civil Service examinations may have been imperfectly and unfairly conducted in some departments, yet it is not the system which is at fault, but its misapplication at the hands of politicians. The appointment of medical men in the Civil Service, solely on political grounds, has for years been a source of scandal and disgrace. Physicians should therefore encourage the thorough enforcement and wider application of the law. On the other hand, some of those who are at present engaged in carrying out this law seem unduly sensitive to criticism, although they are by no means above it. We are quite convinced of the essential accuracy of Dr. Dawbarn's statements. Is has long been known that the methods of appointment of police surgeons have been essentially political.

THE HOSPITAL SATURDAY AND SUNDAY COLLECTION.

THE Hospital Saturday and Sunday Association is again actively at work urging the people to make the annual contribution to the support of the hospitals. The usual figures showing the number of our hospitals, of beds, and the cost of maintenance are given. We are told that the amount of free work done in the hospitals has increased nearly ninety per cent. during the past ten years. The sum of about $300,000 has to be made up every year in order to keep these institutions from

debt, and to this sum the Hospital Saturday and Sunday collection adds about $50,000.

If the free work of the hospitals increases at the same rate in the next ten years, it looks as though New York would get into a similar condition to that which London is in to-day, viz., with an annual deficit of a quarter to half a million dollars, and a thousand or more beds empty because of lack of money.

A good deal of hope has been placed upon the Hospital Saturday and Sunday Association, and it has done excellent work, not only in raising money but in letting people know the exact status of the hospital charities. The annual sum which it collects, however, is but a small one relatively, and it has not increased in any such ratio as have the wants of the hospitals.

We trust that more will be obtained this year than ever before.

CHLORIDE OF AMMONIUM IN WINTER COUGH.

Dr. William Murrell, of London, possesses high scientific attainments combined with a rare talent for getting up a new cough remedy every year. Terebene, apomorphia, sirup of tar, have all been recommended as marvels of therapeutic utility. For the coming winter, Dr. Murrell proposes to give us chloride of ammonium inhalations. This is not a new thing, but it is served in a little different style. Dr. Murrell, however, does not depart entirely from his earlier loves, for he usually employs the chloride of ammonium vapors as a vehicle for using terebene, sandal-oil, or some other balsamic compound.

We rejoice to see that Dr. Murrell possesses not only an original and observant mind, but that he has a sense of humor which adds much to the interest of his clinical notes. In illustration of the value of the ammonium inhaler, he cites the following case :

"N. B——, a general, retired. Is deaf. Has been deaf for years. Was in the artillery. Says all gunners are deaf, so that they never hear anything not good of themselves. Has strange noises in his ears. Dislikes any noise in a room, especially rattle of knives and forks at dinner. Prefers dining alone on this account. General condition very bad, partly from want of exercise. Has consulted all the specialists, and has had his ears examined with many strange instruments. Says that the advantage of consulting many doctors is that no two of them agree, and you are not alarmed by what they tell you. Not much in favor of inhalers. Tried one once, but it blew up. Is introduced to the inhaler, and takes to it kindly. Chloride of ammonium used first alone and then with pinol. Purchases one for himself, and at end of month writes to say it has done him much good."

This is a report of a case full of practical suggestiveness.

The following note is almost equally valuable :

"Miss A. W——, singer, contralto, often loses her voice, especially when she has an engagement. Chest and vocal cords healthy. Thinks symptoms partly due to nervousness. Voice uncertain, and apt to give in the wrong place. Something wrong with an upper C. Uses the chloride of ammonium inhaler, and takes phytolacca assiduously for a couple of days before singing. Maintains that it does her good. Impossible to contradict a lady, so treatment continued."

We trust that Dr. Murrell's politeness had its therapeutic reward. The inhalations of ammonium should be taken once to thrice daily, for half an hour at a time.

THE FUNCTIONS OF THE TRACHEA.

The tracheæ are all the respiratory organs which insects possess, and their physiology would be of great interest no doubt to this class of animals. The trachea of man, however, is only a short, membranous tube, simple both in structure and function. But its special physiology has also been recently elaborately studied by M. Nicaise, who presented a *résumé* of his work to the Paris Académie des Sciences.

In the state of normal, calm respiration the trachea remains slightly contracted and does not change its volume appreciably. The posterior extremities of the annular cartilages are almost in contact, and the membranous portion lies in a linear fold.

During strong respiration—in crying, groaning, singing, etc.—the trachea is dilated and lengthened while the larynx rises; in inspiration the trachea shortens and contracts again. There occurs, therefore, a rhythmical change in the calibre of this tube, the exact degree of which can be measured. The dilatation is in proportion to the force of expiration, and is greatest in the upper part. This dilated trachea acts as an elastic tube compressing the contained air. By virtue of this property it serves an important use in the production of the voice, in singing, speaking, etc. Modifications of the singing voice and of the capacity for speaking may be caused by pathological changes in this organ.

ASYLUM PHYSICIANS NOT PERMITTED TO TESTIFY.

Reuben A. Holder, who had been a patient at the New York City Asylum for the Insane for some eight months, was brought before Justice Patterson at Supreme Court Chambers upon a writ of *habeas corpus*. At an *inquirendo de lunatico*, ordered before Justice Andrews and a jury, the medical superintendent, Dr. Bond, was put upon the stand. The attorney for Holder objected to the doctor's testimony upon the ground that the relation of physician and patient had existed, and was therefore inadmissible under section 834, Code of Civil Procedure, "A person duly authorized to practise physic or surgery shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity."

The Court reserved decision until after recess, when the objection was sustained. In rendering this opinion Justice Andrews said that during the recess he had conferred with several of his associates, two of whom were sitting at General Term.

The same objection was made to the testimony of the examiners who gave the certificates upon which the patient was admitted to the Asylum. This objection was overruled.

One of the Asylum attendants was permitted to testify, and this was all the testimony given regarding the patient's mental condition since his admission to the Asylum eight months before. Under such circumstances it is not to be

wondered at that he was declared sane. It did seem something of a farce to see an attendant testify regarding a person's sanity while the Asylum physicians sat in the court-room, their lips being sealed. This may be just and good law, but for a fair and just scientific inquiry most absurd.

Under such rulings all patients might be discharged, regardless of their mental or physical condition, unless the city went to the expense of employing outside physicians to examine the patients. One cannot but wonder if this patient were to bring suit against the city and the Asylum physicians for damages for detaining a sane person in the Asylum the same ruling would hold, and if so, what protection an Asylum superintendent has against such suits.

MEDICAL SOCIETY PRIZES.

The prizes of the Académie de Médecine of Paris, for 1889, have just been awarded. There are some twenty in all, the sums ranging from $100 to $1,000. A perusal of the titles of winning essays inclines one to the view that no very brilliant work results from the offering of these large sums of money. A prize of $100 dollars is given for an "Elementary Treatise on Human Physiology;" $300 is awarded for an essay on "Anomalies of Vision;" $200 is given the author of an essay on the "Different Methods of Doing Cæsarean Section." A prize is given for an essay on "Gaseous Tumors of the Neck," and one for an essay on "Vesico-vaginal Fistula." Half of the 5,000 franc prize is given to the author of a work on the "Surgery of the Kidneys."

It need not be said that such prizes were either unworthily awarded, or the committee having such matters in charge had not the latitude allowed it that obtains on this side of the Atlantic. It is a standing and well appreciated fact that few of the essays submitted for society prizes are worthy of any notice whatever. In truth, there is not a proper incentive for such work, compared with that of offering good papers to widely circulated journals, and obtaining thereby a well-earned and wide reputation for well doing. Many of our larger societies each year report through their prize committees that no essay worthy of a prize has been offered, and, consequently, no prize is given. The reason is obvious enough. The medical journals absorb readily the best work of the best writers and make it current literature, instead of its being the limited edition of prize essays published under the sanction of a society.

ELECTRICITY IN RESPIRATORY FAILURE.

A few years ago Professor Ziemssen had an opportunity of applying the galvanic and faradic currents directly to the living human heart. He stated that as a result of his experiments the heart did not react to faradic electricity by percutaneous faradization; but that it did respond like other muscles to galvanic stimulation. He found that he could even change the rhythm of the heart in accordance with the interruptions of this current.

Dr. H. A. Hare, however, has recently published an article (*University Medical Magazine*, November, 1889) in which he contradicts to some extent the statements of Ziemssen. He found that in anæsthetized dogs a faradic current placed over the course of the phrenic nerve would not only stimulate the diaphragmatic contractions, but inhibit the movements of the heart by its action on the vagus. In cases of drowning, therefore, or of respiratory failure during anæsthesia, the use of a faradic current over the neck to stimulate the phrenic nerve would, he thinks be attended with much danger, for this nerve runs so close to the vagus that if it were excited inhibition of the heart would also be very likely to follow. He adds:

"Against the reflex excitation of respiration there cannot be the same objection. The electric brush produces a more powerful effect upon the terminal extremities of the sensory nerves than any known method of stimulation. Far more powerful than the douche and than abdominal applications of ether, it should be used under all circumstances when death threatens from respiratory failure. It should not, however, be applied to the neck, but a sponge electrode being placed at the base of the ribs the brush should be applied at intervals to the epigastrium, to be removed when inspirations result, and reapplied when breathing movements cease. If artificial respiration is being carried on by Sylvester's or other of the recognized mechanical methods, the wire brush should be applied during the inspiratory movements."

The same objection to the use of a faradic current over the neck in respiratory failure would hold against the galvanic; and we must infer that the use of electricity in these conditions is to be made with caution. The galvanic current applied directly over the heart might possibly stimulate that organ if it had stopped beating; but it should not be applied over the neck. The faradic current can be safely employed over the chest and epigastrium, but its chief effect is by its cutaneous stimulation.

LOOSE PRESCRIBING.

How many physicians ever stop to consider the harm they do themselves and each other, as well as their patients, by the habit of loose prescribing? By loose prescribing we mean the careless giving of a verbal or written prescription to a patient, or it may be a friend or a friend's friend, without taking the common-sense precaution of finding out what ails the person to whom the advice is given.

That this is but too common a custom needs, unfortunately, no argument, for who can affirm, with his hand over his heart, that he is guileless of the fault? It is so easy to recommend a little dose of calomel if a friend tells you that he is bilious, or some quinine if he has a cold, or even fifteen grains of antipyrin if he asks you what to do for his wife's headaches. You know the man doesn't feel ill enough to put himself formally under your professional care, but merely wants a little something to straighten himself out. You don't wish to offend him, so you give him "a little something," hoping that it won't do him any harm anyway; and he goes off content, and with the feeling that you are a very nice, obliging fellow. But, supposing that your friend is the regular client of another physician, have you been just to your confrère? And supposing that he is your own patient, have you been just to him in letting pass the first symptoms of what may be the beginning of a serious illness, which might, with a little care, be throttled before it has gotten too firm a hold upon him? And in such a case have you been just to yourself,

in endangering your reputation by failing to recognize these premonitory symptoms of disease? Of course not. You are guilty in every instance, and if no evil consequences ensue, put it down to your good luck, and don't swell yourself up with the idea that you are a good fellow and a smart doctor.

But there is another, and wholly reprehensible, method of loose prescribing, and one that is indulged in all too freely. For instance, a friend meets you casually, and in the course of conversation tells you of a friend of his who is sick with, we will say, malaria. He is under the care of Dr. Blank, and has been taking quinine, but doesn't seem to improve very rapidly. You say, thoughtlessly, it may be, "Why doesn't he take Warburg's tincture?" He does take it, on your recommendation, conveyed to him by his and your friend, and believes he recovers more rapidly. His own doctor's stock falls and yours rises, but have you really gained by it? Not in your own estimation, if you are the honorable man we hope you are.

Gentle reader, dwell for a moment upon the responsibilities of your noble calling, and when you are tempted to prescribe in a loose and off-hand way—don't.

HYGIENE WITH A VENGEANCE.

A WRITER in the *Northwestern Lancet* has been studying the subject of menstruation among school-girls, and comes to the conclusion that all girls should be kept out of school during their first menstrual year, while, if they have any tendency to pain, they should be put to bed during the whole time of menstruation. If people followed this advice, nearly every girl would lose a year out of her educational life, and a good many would lie in bed sixty days out of every year. Such advice is ridiculous, and it is unfortunate that it should ever appear with any weight of medical authority.

NON-TUBERCULAR HÆMOPTYSIS.

SIR ANDREW CLARK, Bart., M.D., though a busy man and no longer young, has not lost his receptivity, or his powers of observation and analysis. About once a year he furnishes the medical world with a new disease, or some fresh interpretation of an old one. To his "venal inadequacy" and "catheter fever" he has lately added a "non-tubercular hæmoptysis of elderly people," and this clinical condition is evidently one that deserves some attention. Like most physicians, Dr. Clark had been in the habit of ascribing all cases of pulmonary hemorrhage, not due to a malignant growth or heart disease, to tuberculosis. He had, however, not very infrequently met cases in which this theory proved unsatisfactory, for the patients were not phthisical, and their hemorrhage did not yield to the ordinary measures, such as rest, ice to the chest, astringents, etc. Since 1875 he had seen twenty cases of this kind in persons over fifty years of age. There was usually a rheumatic history. In two cases where death occurred, no tubercles were found, but emphysema, congestion, and scattered small hemorrhagic extravasations. The seat of hemorrhage was in the neighborhood of the emphysematous patches, and many of the terminal arteries were found to be diseased.

Dr. Clark frames the following as the results of his inquiries:

1. That there occurs in elderly persons, free from all disease of the heart and lungs, a form of hemorrhage arising out of minute structural alterations of the terminal blood-vessels of the lungs. 2. That these vascular alterations occur in persons of the arthritic diathesis, resembling the vascular alterations found in osteo-arthritic articulations, and are themselves, probably, of an arthritic nature. 3. That, although sometimes reaching to a fatal issue, it usually subsides without the supervention of any coarse anatomical lesion of either heart or lungs. 4. That it is aggravated or maintained by the administration of astringents, and by indulgence in liquids to gratify the thirst caused by them. 5. That the best treatment is diet and quiet, cutting off the supply of liquids, quieting the cough, calomel and salines, alkalies and iodide of potassium, and free counter-irritation.

YEAST-PLANT PATHOLOGY.

WE observe, at periodical intervals, the appearance of medical contributions upon the subject of "clinical morphology," sometimes illustrated with figures suggestive of ancient griffins and dragons, but which, we learn from the context, are only yeast-plants in various stages of growth. These articles are becoming more numerous of late, and we note that this yeast propaganda, in combination with the *crypta syphilitica*, has reached and endeavored to leaven the American Medical Association. It seems hardly possible that any medical men can be caught by the transcendental gibberish which goes with the yeast pictures and the preachers of "clinical morphology." Their doctrine, so far as we can learn, consists in this: That ingested foods ferment, and always through the yeast-plant; that the spores of this pan-pathogenic sporule pass into the blood, and there continue the dire fermentative processes, causing phthisis, dyspepsia, cirrhosis, etc. The learned "clinical morphologist" pricks the finger, takes a drop of blood, looks at it under the microscope of some miraculously high power, and, "if conscientious," sees a few hæmatoblasts and disintegrating blood-cells, which he solemnly avers to be yeast-spores. If the patient's blood is full of these, he must live upon chopped meat and hot water, in order to wash them out. It is astounding that educated men will go on for years asserting certain things to be facts, without ever trying to demonstrate them as such. This is the case with the clinical morphologist and his ridiculous *eidolon hæmatos*. Although it would be perfectly easy to prove or disprove the existence of his spores by modern mycological methods, this is not done, but shrivelled blood-cells and hæmatoblasts are figured as parasites, with the help of misused microscopes and a fantastical imagination. Medical men have a right to pursue a vagary, if it is a harmless one, and often it may be connected with some useful therapeutic procedure, like the drinking of hot water, and the use of non-fermentative food. But the time has passed when the unspeakable nonsense of the yeast-spore, and the spook pictures of it, and crypta syphilitica, should be tolerated in medical literature or before medical societies.

They Might Try Stavesacre.—The medical profession of Cincinnati is infested with all sorts of parasites.—*Medical News*, December 7, 1889.

News of the Week.

Typhus-fever Cases in New York.—The two cases of fever which arrived two weeks ago, on the ocean steamship Westmoreland, have been transferred to North Brother Island by the Health Department. One is undoubtedly a case of typhus, but the other has not declared itself and is still under observation.

Death from Chloroform.—A death from chloroform is reported in the issue of December 21st of the *British Medical Journal*. The patient was a female, forty-one years of age; the operation was trachelorrhaphy, and was duly completed. On removing the "face piece" retching occurred —more chloroform given. Suddenly breathing ceased. The heart, examined before the operation, was declared healthy. No autopsy was made.

Dr. Bernard Ruppe, an old and well-known German physician, was found dead in bed, December 29th. He was born in Saxony fifty-six years ago and received his medical education at the university in Jena. He came to this country almost immediately after receiving his diploma, and established himself as a practitioner in the Eighth Ward. He was physician to the German Society, and consulting physician to the German Hospital.

Diphtheria in Illinois.—Diphtheria appears to be raging with considerable virulence in Southern Illinois. Dr. Toby, of Macon, states that he has treated seventy-five cases recently, and the public schools there are closed on account of it. Dr. S. J. King, of Illopolis, Ill., reports treating thirty-seven cases, and Dr. S. W. D. Mayes, of the same place, twenty cases; while at Clinton the post-office has been quarantined on account of this disease.

Scientific Penalogy.—A singular association, the "Beccaria Club," has recently been organized to promote the study and practice of scientific penalogy. No one is permitted to be a member unless he is or has been, in some way, directly connected with prison management, or with some regularly incorporated prison association, or has written some work on penalogy. We do not recognize the name of a single physician among those stated as constituting its members, although we should think that such an association would be very incomplete without a medical representation.

Sulphur Worthless for Fumigation.—It appears that the prevailing method of disinfection by means of burning sulphur is considered by some of the leading bacteriologists as of less value than it has heretofore been considered. Dr. J. G. Johnson read a paper before the Kings County Medical Society on the 17th ult., in which he stated that he had proved the present system of fumigation as worthless for the destruction of disease-germs; that the fumes of burning sulphur do not penetrate woollens as disease-germs do. He also stated that he had propagated diphtheria from the clippings of blankets after they had undergone a thorough process of fumigation by burning sulphur. Dr. Prudden, of the New York City Board of Health, appears to have come to the same conclusion, and in both New York and Brooklyn currents of steam are to be recommended for disinfecting purposes instead of burning sulphur.

St. Luke's Hospital, New York.—Dr. T. Halsted Myers has been appointed Attending Orthopædic Surgeon to this hospital.

A Projected Italian Hospital.—An appeal has been made for the establishment of an Italian hospital in this city. It is difficult to understand what necessity there can be for such an institution, in view of the fact that in none of the well-established hospitals of this city are Italians denied admission or treatment.

The Medical Society of the State of South Carolina celebrated its one-hundredth anniversary at Charleston, December 9th, by an oration in South Carolina Hall by Dr. Kollock, followed by a dinner at the Charleston Hotel. The Medical Society of South Carolina ranks among the oldest of its kind in America; the three older than it being the New Jersey State Medical Society, founded in 1756; Massachusetts Medical Society, founded in 1781; and the College of Physicians, Philadelphia, founded in 1787.

Boston has a Leper who came from St. Louis, but has been detained in quarantine.

The German State Examining Board recently held its annual examinations. Among the 683 applicants, 504 were passed.

Circumcision not of Sanitary Origin.—The idea that the ceremony of circumcision among the Jews was of a sanitary origin is strenuously denied by Mr. C. Roberts, of London, who thinks it was of the nature of a sacrifice, the prepuce being the easiest, and, indeed, the only part of the body of an infant which could be removed with safety. It is quite possible it is remotely connected with phallic worship, which is common enough at the present day in India and other parts of Asia. It is practised by other races than the Jews—some African tribes—who are not far advanced in sanitary knowledge. Mr. Roberts insists that the removal of the prepuce should not be undertaken except for very good reason. In his experience it does not necessarily prevent masturbation, but may even encourage it.

A Memphis Medical Journal devotes a page to advertising its undertakers. The wood-cut of the coffin is an artistic piece of work, and it is surrounded by assurances, in well-chosen English, from which we infer that the patients of our esteemed contemporary will receive conscientiously elaborate mortuary disposal.

Contaminated Water and Typhoid Fever.—An epidemic of typhoid fever prevails in Berks County, Pa., caused by contaminated drinking-water. The supply is from a stream along which the city erected a pumping-stand, and arranged to get its supply of water for household purposes in a few weeks. The carcasses of diseased cattle are said to be soaking in the stream above the infected district.

Poisoned by Self-prescribing.—A man in Newark died on Wednesday after having taken a hypodermic injection of pilocarpin for morphine. The medicine was sold him by mistake of the druggist. Very bad both ways.

Intubation of the Larynx has been abandoned by Thiersch, of Leipsic, who claims to have given it a fair trial, but prefers tracheotomy.

The Emperor of Germany and his Ear Trouble.—The German papers report that the trouble in the Emperor's ear, chronic suppurative otitis, is giving him considerable pain, and that he is constantly under treatment for it.

A Gift to the Maine General Hospital.—By the will of the late Dr. H. H. Hill, of Augusta, Me., his residuary estate is left to his executor to be invested, the net income, and part of the principal if necessary, to be devoted to the support of his wife. Upon her decease he directs that from any of the estate which remains small legacies are to be paid to several of his nieces, and his residuary estate is then to pass to the Maine General Hospital. The estate is valued at $40,000.

Contracted Diphtheria from a Patient.—An interne of the Charité, of Berlin, recently contracted diphtheria from a patient and died.

The Health of Connecticut.—Dr. Lindsay, the State Secretary of Health of Connecticut, considers that a large percentage of the deaths from diphtheria, scarlet fever, typhoid fever, and such other preventable diseases, results from the inefficiency of the Health Boards of towns and the general neglect of well-known precautions. In thirty-four towns of the State no deaths were reported during November. Nine of these towns were in New Haven County, seven in Litchfield, five in Tolland, three each in Hartford, New London, Fairfield, and Windham, and one in Middlesex County. Wallingford, which has a population of six thousand, did not report a single death during the month. In addition to Wallingford, the New Haven County towns in which death was escaped through the month were Bethany, Madison, Middlebury, North Branford, Oxford, Prospect, Southberry, and Wolcott. The Litchfield County towns reporting no deaths during November were Cornwall, Goshen, Kent, North Canaan, Norfolk, Warren, and Washington. In Fairfield County there were only three such towns, being Brookfield, Sherman, and Trumbull. Tolland County showed the towns of Bolton, Coventry, Ellington, Somers, and Tolland as reporting no deaths in November. In Hartford County the towns were Bloomfield, Marlborough, and Newington; in Windham, Ashford, Hampton, and Sterling; in New London, Bozrah, Salem, and Ledyard. The only town in Middlesex County reporting no deaths for the month was Middlefield.

A Singular Interment.—On November 26th last Dr. John W. Bartlett died in Los Angeles, Cal. In accordance with the terms of his will and well-known wishes, his remains were cremated and forwarded to Milwaukee by mail. They consisted of a whitish powder, and were enclosed in a small rosewood box, 11½ inches long, 8 inches wide, and 3 inches deep. The interment of this casket took place in Dr. Bartlett's family plot at Forest Home Cemetery, Milwaukee, on December 13th. Dr. Bartlett was born in Portsmouth, N. H., 1816. He graduated from Yale College and immediately removed to Milwaukee, and subsequently to California. He was a member of the American Medical Association for many years, vice-president of it in 1872, and one of its censors for a long time. He was one of the vice-presidents of the International Medical Congress in 1876, and was president of the Wisconsin State Medical Society.

The New York Hospital has been lighted throughout by electricity, and physicians, patients, and management are alike gratified. Sanitary motives alone dictated the change, for it was thought that a better and more even temperature could be maintained, and a less vitiated atmosphere be secured in the wards, where these are all-important, than with the use of gas. There would be no consumption of the oxygen with the electric lights, as there had always been with gas-lights, and so the change was made. A practical electrician put into the building seven hundred Edison lamps and the necessary wires and switches, and connected them with the service wires out in the subways. The outfit for the operating-rooms includes a series of movable reflectors, which will enable the performance of operations at any hour of the night, with a facility equal to that experienced in daylight. In the wards the change was particularly noticeable, and was highly appreciated by the patients.

The Methodist Episcopal Hospital in Brooklyn.—The second annual report of the Methodist Episcopal Hospital in the city of Brooklyn has just been issued, and it shows that that youthful institution has prospered. During the period covered by the report—from November 1, 1888, to October 31, 1889—611 patients have been treated, of whom 305 were cured of the diseases afflicting them; the receipts from various sources amounted to $54,497.38, and the disbursements to $54,039.64, thus leaving on hand a balance of $447.69 at the end of the hospital's second year of existence. The cost of running the hospital itself was $33,708.04. In addition to this financial statement should be added the fact that the endowment fund has been increased during the year from $71,000 to $92,000, with about $9.000 worth of real estate still to be added. As far as the patients received are concerned, the hospital is absolutely non-sectarian. People of all creeds and nationalities have been treated, and some—very many—who had no religion at all were cared for. We are pleased to note the prosperity of this worthy institution. Although with a very sectarian name, we are glad to learn that it has non-sectarian principles. Think of it! actually treating many sick "who had no religion at all." Can there be any greater stretch of charity than that?

Co-operative Medicine.—A bill has been introduced in the Legislature of this State incorporating the People's Co-operative Medical Association of Brooklyn, which is to furnish cheap medical attendance and medicine. Capital, $1,200.

Veterinary Medicine.—It often becomes a serious question with us why, in view of the overcrowded medical profession, more bright men do not take to veterinary medicine. Men are willing, as a rule, to pay more for the treatment of their horse than for themselves, consequently the "horse doctor" is quite in demand and willingly paid, and whatever else the patient may do in the way of kicking, such equine perversity is never in the direction of the bill. The field invites earnest laborers who wish to earn an honest and honorable living. There is certainly a demand for such a study, as already the large universities are founding veterinary annexes under the supervision of competent veterinarians.

Diphtheria is prevailing in many towns west and southwest, a thing to be expected at this season.

Physical Troubles of the Great Folks.—"Uneasy lies the head that wears a crown" appears in these days to be true not only from the cares of royalty, but also from their inherited or acquired bodily ailments. The Czar of Russia is said to be hypochondriacal and terribly shaky in the nerves. The Czarina is even worse, and is subject to attacks of intense nervous prostration. The Emperor of Austria is physically healthy enough, but in consequence of the suicide and the sad circumstances attending the death of his son is a melancholy, heart-broken man, while his wife is said to be a martyr to sciatica, rheumatic fever, and melancholia. She belongs to the same family which numbers among its members the crazy kings of Bavaria. The North Germans declare that the King of Wurtemberg is more than half demented. King Milan of Servia is haunted by a dread of assassination, and the Sultan of Turkey is in constant fear of the fate of his predecessor. The physical defects of William II. of Germany give him almost constant pain, and are well known. The King of Holland is paying the penalty of a dissipated life. The King of Italy suffers from chronic gastric derangement, said to be the result of excessive smoking of green cigars. The infant King of Spain inherits from his father weaknesses which will probably make his life miserable. The King of Belgium is lame. The Queen of Roumania is troubled by hallucinations. Queen Victoria may be physically well enough, but she is an irascible old lady, and notoriously difficult to manage. The list might be continued still further.

Reviews and Notices of Books.

Wood's Medical and Surgical Monographs. Consisting of Original Treatises and of Complete Reproductions in English of Books and Monographs Selected from the Latest Literature of Foreign Countries, with all Illustrations, etc. Vol. III. New York: William Wood & Co. 1889.

This volume of the "Monographs" comprises the numbers for July, August and September. The first number contains essays on "Cancer and Cancerous Diseases," by Sir Spencer Wells; "Cardiac Dyspnœa and Cardiac Asthma," by Dr. S. von Basch; "The Influence of Menstruation and of the Pathological Condition of the Uterus on Cutaneous Diseases," by Dr. L. Grellety; "Tension as met with in Surgical Practice; Inflammation of Bone; Cranial and Intracranial Injuries," by Mr. Thomas Bryant, and "Antisepsis and its Relation to Bacteriology," by Dr. J. Neudorfer. In the second number we find the "Manual of Hypodermic Medication," by Drs. Bourneville and Bricon, which has been translated from the second French edition by Dr. A. S. Currie, and revised and rearranged for American readers by Dr. Charles Rice, of this city, whose notes add not a little to the practical value of the work. There are also short articles on "The Treatment of Syphilis at the Present Time," by Dr. Maximilian von Zeissl, and "The Treatment of Inebriety in the Higher and Educated Classes," by Dr. James Stewart. The September number contains the index and table of contents for the volume, and in addition five monographs on "Congestive Neurasthenia or Nerve Depression," by E. G. Whittle, M.D.; "The Art of Embalming," by Benjamin Ward Richardson, M.D.; "The Etiology, Diagnosis, and Treatment of Tuberculosis," by Dr. H. von Ziemssen; "Psycho-therapeutics, or Treatment by Hypnotism," by Dr. C. Lloyd Tuckey, and "Sexual Activity and the Critical Period in Man and Woman," by Dr. Louis de Séré. It is impossible to present a critical review of all these papers, thirteen in number, the titles of which we have just enumerated, but a mere catalogue of them is sufficient to indicate the nature and scope of this excellent series of monographs, and to show that any practitioner, whatever his special tastes may be, cannot fail to find there many articles each year, any one of which would repay him for his subscription to the entire work.

Lectures on Massage and Electricity in the Treatment of Disease. (Masso-electro Therapeutics.) By Thomas Stretch Dowse, M.D., Fellow of the College of Physicians of Edinburgh; Formerly Physician Superintendent of the Central London Sick Asylum; Associate Member of the Neurological Society of New York, etc. Bristol: John Wright & Co.

In this volume we have a conveniently arranged mass of information on the still but imperfectly understood subject of the treatment of disease by massage and on the equally imperfectly understood but more abused method of treatment by electricity. Thirteen lectures are devoted to the former and but two to the latter. The author is very fair in his claims for both massage and electricity, and regards neither agent as more than an aid to treatment, and deprecates the too great praise of either. After a general description of massage and review of the principles involved in its application, the author takes up each region of the body in turn and gives the indications for, and mode of applying, the agent for the diseases and morbid conditions there located. The descriptions are clear and easy of comprehension by the reader, and are rendered still more satisfactory by the judicious use of fairly well executed illustrations. The book is a good one.

A Reference Handbook of the Medical Sciences. Embracing the entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. Illustrated by Chromolithographs and Fine Wood Engravings. Edited by Albert H. Buck, M.D., New York City. Volume VIII. New York: William Wood & Co. 1889.

The appearance of this eighth volume marks the completion of a work which is unique in medical literature. There is no lack of encyclopædias of medicine, but those published up to this time either relate to special branches of the healing art or are so bulky as to render them in great measure useless to the practical physician. In this work, however, every subject of interest to the practitioner of medicine is fully treated, yet the whole is contained within the limits of eight octavo volumes. The volume before us contains the articles from "Wormseed" to "Zymotic Diseases," an appendix of papers which were not inserted in regular alphabetical order, and a very complete index to the entire work. The latter, it is needless to say, adds greatly to the value of the work. "Yellow Fever," "Brain," "Spinal Cord," "Intussusception," and "Lymphatic System" are the articles of most prominence in glancing through the volume, the illustrations in the last named being conspicuous for their beauty and clearness. We can only repeat at this time what we have so often said in commenting upon the previous volumes, that we regard the work as invaluable to the practitioner of medicine, whether he be a general practitioner or a specialist. There is almost no subject even remotedly connected with his art concerning which he may not find all necessary information within the covers of these eight volumes. The editor and publishers are to be congratulated upon having rendered such a benefit to the science of medicine. We shall take an early opportunity now that this most valuable work is completed to give to our readers such a critical review of the entire series as its merits and importance entitle it to.

Essentials of Physiology. By H. A. Hare, M.D. Pp. 193. Philadelphia: W. B. Saunders.

Essentials of Pathology and Morbid Anatomy. By Armand Semple, M.D. Pp. 160. Philadelphia: W. B. Saunders.

Both of these students' manuals belong to the "Question Compends" series. The one on physiology has been favorably noticed in these columns and is now in its second edition. We have seen no reason, in examining the book a second time, to change our opinion that it stands at the head of its class.

It is a somewhat bold task to attempt this line of writing with reference to pathology and morbid anatomy. So many questions in these subjects are still debatable ground that the difficulty lies in making statements which are decisive and yet not outside the pale of accepted doctrine. Dr. Semple has succeeded, however, in making his task a profitable one for the reader. The volume supplies a place heretofore not well filled in students' series.

Diseases of the Eye. A Practical Treatise for Students of Ophthalmology. By George A. Berry, M.B., F.R.C.S. Ed; Professor of Ophthalmic Surgery, Edinburgh Royal Infirmary, etc. 8vo, pp. 670. Philadelphia: Lea Brothers & Co. 1889.

Mr. Berry gives the profession a very useful and practical work on diseases of the eye. The arrangement is thoroughly clinical in character, and as such commends itself to the earnest student. The illustrations of different eye diseases, which are numerous and typical, are fine specimens of chromo-lithographic art. The section on refraction is an admirable *exposé* of the present state of our knowledge on the subject, and is the leading feature of the work. The third and last section treats of the classified operations upon the eye and its appendages, and gives all the well-approved methods, together with the author's views upon the same. The author has not given much attention to pathological questions, save only when required to do so by way of explaining a method of treatment which could not be made intelligible otherwise.

Transactions of the American Orthopedic Association. Vol. I. 1889.

This very neatly printed and pleasing volume contains the transactions of the first two meetings of the American Orthopedic Association, the report of the first meeting, however, being quite brief. The work done at the second meeting, in Washington in the fall of 1888, is fully reported, and certainly shows that the Association was not formed in vain. The "Transactions" form a very valuable addition to the literature of orthopedic surgery in this country.

The Washington Life Insurance Company. Historical, Actuarial, and Medical Statistics. New York: Published by the Company. 1889.

This is a large volume of over one hundred and fifty pages, fairly bristling with statistics relating to the business of life insurance. The book is well gotten up, and is one that will have a permanent value as a work of reference for writers on disease in its etiological aspect.

Movimento Clinico nello Instituto Ostetrico-Ginecologico della R. Università di Bologna, Diretto dal Prof. Cav. Carlo Massarenti. Bologna.

A brief report of the cases treated at the Obstetrical Institute attached to the University of Bologna, for the year ending July 31, 1889.

La Uretrotomia Interna en la Isla de Cuba es tan Inocente como la Dilatacion Progresiva. Por el Dr. Ignacio G. Plasencia. Habana: G. Cacho-Negret. 1889.

In this work the author argues well in support of the operation of internal urethrotomy in preference to gradual dilatation for the relief and cure of stricture of the urethra.

Transactions of the Southern Surgical and Gynæcological Association, 1888. Vol. I., 1888. Birmingham, Ala.: Caldwell Printing Co. 1889.

Transactions of the Gynæcological Society of Boston. New Series. Vol. I. Boston: Cupples & Hurd. 1889.

Transactions of the Illinois State Medical Society for 1889. Chicago: Jameson & Morse Co. 1889.

These volumes, though primarily of local interest, yet contain many valuable contributions to American medical literature. It is satisfactory to note the uniform arrangement and typography which now prevail in all our State and local society reports. These three reports, especially, reflect great credit on their respective publication committees.

A Treatise on the Science and Practice of Midwifery. By W. S. Playfair, M.D., LL.D., F.R.C.P.; Professor of Obstetrical Medicine, King's College, London, etc. Fifth American, from seventh English edition, with Notes and Additions. By Robert P. Harris, M.D. 8vo, pp. 659. Philadelphia: Lea Brothers & Co. 1889.

Excellent as is the English edition of this standard work, the American edition is a considerable improvement upon it, by the valuable additions of the American editor, referring to the more recent advances in obstetric surgery. The American editor has brought up the work to date on these subjects, and gives interesting statistical records to the close of 1888.

Chemistry, General, Medical, and Pharmaceutical, including the Chemistry of the United States Pharmacopœia. A Manual of the General Principles of the Science and their Application in Medicine and Pharmacy. By John Attfield, F.R.S., M.A. and Ph.D., Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, etc. Twelfth edition. 12mo, pp. 770. Philadelphia: Lea Brothers & Co. 1889.

The first edition of this standard manual was issued in 1867, since which time twelve editions have been issued. The present one meets the demands of a leading textbook, contains the discussion of the most recent researches in the science of chemistry as seem necessary for the demonstration of the latest developments of chemical principles and the latest applications of chemistry in pharmacy. The work also includes the chemistry of the United States, British, and Indian Pharmacopœias.

Egypt as a Winter-resort. By F. M. Sandwith, F.R.G.S. 153 pp. London: Kegan, Paul, Trench & Co.

The writer aims to answer the inquiries of increasing numbers who visit Egypt for health or pleasure, with the present increased facilities for travel. He states that during six years, ending in June, 1889, only nine British visitors to Cairo have died, and seven of them arrived there ill of incurable diseases. The advantages of Egypt he thus summarizes: 1. A dry and exhilarating air which acts in itself as a tonic, and enables visitors to be out of doors in sunshine the whole day. 2. An almost complete absence of rain, and of fog, and of clouded leaden skies. 3. The absence of extreme cold, so that the invalid by closing his windows at sunset need never breathe air colder than 55° F., even without any artificial heat. 4. The absence of strong winds at Cairo and Luxor, though individuals occasionally require special protection on the Nile. 5. The interest and relaxation of mind inspired in a country where may be studied the remains of the ancient Egyptians, Persians, Greeks, Romans, Arabs, and Turks. 6. The presence in a perfectly healthy Oriental city of most available European luxuries, and a large and hospitable English society. 7. The absence of moribund phthisical patients, who find Egypt too far from home. 8. The facilities for riding and driving, and for playing all out-door games.

A Treatise on Gout. By Sir Dyce Duckworth, M.D., Physician to, and Lecturer on Clinical Medicine at, St. Bartholomew's Hospital, London. 8vo, pp. 476. Philadelphia: Blakiston, Son & Co. 1889.

It is refreshing to a degree to obtain the experience of a typical general practitioner upon a disease which has such general manifestations throughout the economy as the one which forms the title of the work before us. While the author apologizes for not being a specialist on the subject, he unconsciously commends his observations the more to the thinking and practical reader. It is not surprising to know that the author is, under the circumstances, eminently practical in his observations and his deductions. While there is nothing startlingly original in the pathogeny or treatment of gout in its multiform varieties, it is exceedingly interesting to follow his suggestions and analyze the force of his clear reasoning. Although he maintains that uric acid is the peculiar irritant, it may nevertheless work its varied evils without, in every instance or in every tissue, giving token of its presence. The phenomena, too, are to be explained by something beyond the resultant effects of aberrant relations of uric acid, something more than a perversion of animal chemistry. In fact, it refers itself to a diathetic tendency, which in this, as in all diseases of an assimilative or secretive character, is controlled by a nervous influence. His methods of reasoning are interesting, instructive, and quite conclusive. A very large part of the work is devoted, very properly, to therapeutics, in which, of course, colchicum, alkalies, regulation of diet, and exercise, receive a full and well-merited share of consideration.

The Physiology of the Domestic Animals: A Text-book for Veterinary and Medical Students and Practitioners. By Robert Meade Smith, A.M., M.D., Professor of Comparative Physiology, University of Pennsylvania. 8vo. pp. 938. Philadelphia and London: F. A. Davis. 1889.

This elaborate and well-illustrated manual is a very satisfactory *exposé* of comparative anatomy, and is an exponent of the laws of modern physiology applied, as far as possible, to the functions of the lower animals. It is, from the present stand-point of our knowledge of physiology, a retroactive study or comparison between corresponding functions throughout a wide range of natural law. Although more especially intended for veterinary students, there is much of interest in it for the student of physiology. In fact, there is scarcely a chapter which does not convey information in a novel and attractive manner. This is particularly the case in those parts of the work treating of the different varieties of apparatus, as applied to the respective functions to be performed in the lower animals, as compared with those in the human being. The subjects of locomotion, digestion, secretion, and procreation are models of clear and satisfactory exposition, and are replete with suggestive and instructive analogy. It compares favorably, as the only English work of its kind, with others of its class in the German and French languages. Of its thoroughly scientific character, and of its admirable arrangement and division of topics, too much of commendation cannot be given.

The Principles and Practice of Surgery. By John Ashhurst, Jr., M.D., Barton Professor of Surgery and Professor of Clinical Surgery in the University of Pennsylvania. Fifth edition. 8vo, pp. 1148. Philadelphia: Lea Brothers & Co. 1889.

The general field of practical surgery is as well worked over in Ashhurst's "Surgery" as in any work of its size in any language. It has thoroughly fulfilled the original design of its author, "to furnish, in as concise a manner as may be compatible with clearness, a condensed but comprehensive description of the modes of practice now generally employed in the treatment of surgical affections." This last edition has been considerably and profitably amplified.

The Urine, the Common Poisons, and the Milk. By J. W. Holland, Professor of Chemistry in Jefferson Medical College. Pp. 84. Philadelphia: P. Blakiston, Son & Co. 1889.

A Laboratory Guide in Urinalysis and Toxicology. By R. A. Witthaus, Professor of Chemistry, New York University Medical College. Second Edition, pp. 73. New York: William Wood & Co. 1889.

These laboratory guides follow the beaten track for the students in the institutions of their respective authors. Both are of the note-book typography and contain interleaves for the student's own observations. Professor Holland's section on the study of milk deserves special notice.

A Surgical Handbook for the Use of Students and Practitioners. By Francis M. Caird, M.D., and Charles W. Cathcart, M.D., Assistant Surgeons Royal Infirmary, Edinburgh. Philadelphia: P. Blakiston, Son & Co. 1889.

Into this pocket manual of 262 pages the authors have condensed the practical parts of surgery, including antisepsis, emergencies, bandaging, etc. In fact it is hard to see how the art of condensation could profitably be carried further. It is just the book to have at hand for ready reference, and is a perfect mine of information systematically arranged.

Obstetrics and Nursing. By Theophilus Parvin, M.D. Pp. 104. Philadelphia: P. Blakiston, Son & Co. 1889.

These lectures were delivered to the pupils of the Philadelphia Hospital Training-School for Nurses, and cover the usual ground. They can be read with profit by all obstetric nurses.

Second Biennial Report of the North Carolina Board of Health. Edited by Thomas F. Wood, M.D.

A systematic report, full of the usual statistical tables, county reports, etc.

Diseases of Women. By F. H. Davenport, M.D., Boston, Mass. 12mo, pp. 317. Philadelphia: Lea Brothers & Co. 1889.

The author attempts no originality, as the work is a compilation from recognized authorities. The treatment is confined to those measures which the writer has found by personal experience to be of most value. Pathological anatomy has been left out. The book has some good points, but is on the whole unsatisfactory. It is evidently written for the Boston student population.

Swedish Movement and Massage Treatment. By Professor Hartvig Nissen, Washington, D.C. 12mo, pp. 128. Philadelphia: F. A. Davis. 1889.

The history of this therapeutic measure is first given, and then a description of its various methods of application. Part II. is devoted to the practical use of these methods in treating the sick. The style is plain and the various movements easily comprehended. Though we are not disposed to underrate the value of massage as a therapeutic agent, we are a little incredulous as to its value in certain maladies mentioned by the author. The book is of value as an introduction to a more elaborate study of the subject.

Extra-uterine Pregnancy. 8vo. pp. 66. Philadelphia: William J. Dornan. 1889.

This discussion is reprinted from the "Transactions of the American Association of Obstetricians and Gynecologists" at their meeting in 1888. The various phases of the question are argued by Drs. Townsend, Price, Montgomery, Wathen, Baldy, Deaver, McMurtry, and Vander Veer.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON THEORY AND PRACTICE OF MEDICINE.

Stated Meeting, November 19, 1889.

R. C. M. Page, M.D., Chairman.

Therapeutic Action of Electricity.—Dr. A. D. Rockwell read a paper on "The General Therapeutic Action of Electricity." The literature relating to the treatment of disease by electricity, he said, had accumulated beyond measure, and yet there existed so little correct appreciation of the physics of this agent that it was necessary to emphasize again and again the statement that electricity is not a simple, single manifestation of natural force, but a generic term including many complex phenomena. Much, indeed, was claimed for it; but it accomplished much, and produced effects widely divergent.

In the first place, it was a stimulant, and a stimulant of the most powerful character. Again, it was a sedative, and one which in some cases was unequalled; and it could generally be relied upon to soothe, in a greater or less degree, a functional hyperæsthetic condition of the nervous system. Furthermore, admitting the recognized significance of the word tonic, and that remedies for improving the tone of the system still held an important place in the classification of the Materia Medica, electricity could not but be regarded as a tonic of a very high order. To produce that tension of the nervous system, and of the muscular fibre generally, so as to enable them to respond to their natural stimuli, the mechanical effects of the faradic current seemed to be especially applicable. Unlike the galvanic current, it possessed no chemical action or reflex effects which need be feared. Properly applied it would not produce any appreciable muscular contractions, and yet it gave passive exercise to all the deeper-lying as well as superficial muscles. The numerous branch-currents, going to and fro, acted as so many shuttlecocks, keeping every atom in incessant disturbance.

Aside from these purely mechanical effects, it was evident that even the induced or faradic current exerted some other and more subtle influence upon the nerves themselves, for by no purely mechanical means could we account for the numerous phenomena that followed its use in diseased conditions. It was the application of the broad therapeutic action of electricity and a knowledge of the details of the general methods of application necessary for its production that had aided in the success of so many charlatans. Electricity, then, after the method of general faradization, might be said to be indicated whenever a constitutional tonic influence was called for.

This law rendered the remedy as valuable to the general practitioner as to the specialist in electro-therapeutics. For the tedious period of convalescence which often followed typhoid and other fevers there was no remedy that was comparable to it, and in a large number of conditions of depressed vitality electricity, in some one of its forms, would prove of service. In addition to giving passive exercise to the muscles, it rendered more natural the processes of secretion and excretion, corrected circulatory disturbances, and afforded tone and strength to both nerve and muscle.

With these general principles in view, we ceased to wonder that electricity was used and recommended for such a variety of diseases, and appreciated the injustice of the criticism which condemned electricity because it was claimed to be of service in so many different conditions. When its therapeutic efficiency was denied, the inevitable conclusion at which those must arrive who had, time and time again, witnessed evidences of its power, was, that he who thus fails in his results is deficient in his experience, is not sufficiently persistent, or has somehow failed in the technique of his applications.

Some of the results in electro-therapeutics were probably due—though only to a limited extent—to physical effects. Thus, there was unquestionably a small amount of heat excited in the tissues by the passage of either form of current. Having spoken of the well-known physical effects of electricity on metals as suggestive of what might be facts in physiology and pathology sufficient to account for some of the therapeutic effects of electrization, he said that these possible physical and physiological changes applied especially to the after or secondary effects of electrical treatment. The chemical or electrolytic influences that were associated with electrical action were practically confined to that form of dynamic electricity which was termed galvanism. Its special utility was in the department of electro-surgery; but it was undoubtedly true that some electrolytic action occurred in all ordinary applications of galvanism to the body, while it was probable that it was a factor of more or less importance in making up the sum of electro-therapeutic effects. A distinction had very justly been made between electrolysis, which was a disintegration and separation of the constituent elements of organized structure, and galvano-chemical cauterization, which produced its effects by means of the acids and alkalies which were liberated at either pole by electrolytic action. It was the chemical galvano-cauterization, and not electrolysis, which accomplished most of the good results that followed intra-uterine applications in cases of endometritis.

Influence on Nutrition.—In its influence on nutrition, however, the physiological effects of electricity are perhaps the most important. The action of either current modified physiological function in various ways. In the first place, it might increase it. The readiness with which the secretion of the salivary gland could be increased was readily demonstrated. Mucous secretions were also very quickly increased by the action of either current, and the effects of electricity were being utilized more and more in diseases characterized by a suppression of the normal mucous secretion. Especially in the so-called dry catarrh was the treatment efficacious. The effects of electricity on the biliary secretion, the gastric juice, and the intestinal fluids were less easy of demonstration; but Dr. Rockwell's experience had been that appetite was sharpened, digestion quickened, and constipation relieved, both by local and general electrical treatment, so rapidly as to make it pretty evident that the gastric and intestinal juices were made to secrete more liberally by the action of the current on the nerves supplying the organs of digestion, rather than on the tissues of the organs themselves. These results had also been recently confirmed by Ziemssen by experiments on animals. Among those affections of the bowels in which electricity was quite certain to exercise a beneficial influence were defective innervation, atrophy of the muscular tissue, digestive atony, and the wide section of diseases comprehended under the name of hypochondriacal and neurasthenic.

Electricity might not only diminish, but it might arrest the physiological activity of the organs of secretion and excretion. When, as in polyuria, the general application of the current was followed by a marked diminution in the flow of urine, it has a desirable therapeutic effect; but the effect now referred to was by no means of this character, and came from the use of currents so strong as to paralyze glandular function. Thus he had known two cases in which lacteal secretion was promptly suppressed by the injudicious use of currents of high tension; although, when properly applied, electricity often had a very beneficial effect in increasing the flow of milk, or in restoring the secretion after it had been temporarily suppressed. As regards the circulation, very sensible modifications might be observed in any strong and prolonged application of either current, and they were generally on the side of an increase in the flow of blood, and some elevation of temperature, with dilatation of the veins. On the absorbents the action of electricity had been found to be of practical value in relieving many hypertrophies, effusions, and morbid growths; and in explanation of this ac-

tion it was perhaps sufficient to say that the effects of electricity on the excretory processes of the body, its direct chemical action, and its influence over the circulation by its power to increase the quantity and quality of innervation received by the blood-vessels, must constitute most important factors in influencing the process of absorption.

Discussion.—Dr. Charles L. Dana said that he did not wish to appear as an apologist for electricity, as that was decidedly not the attitude which he held. He believed that what was useful in therapeutics would surely stay, and what was not would be gradually dropped, without any reference to dogmatic assertions of individuals or the high polemics of learned societies. He took this opportunity, however, of saying a few words about a little ewe-lamb of electro-therapy, viz., static electricity, and hoped to correct some erroneous views which had become current, and to state some facts about it which were not entirely old.

Definition of Electricity.—A recent writer on electro-therapeutics and physics had referred to electricity as a form of energy. This was a fundamental error, and showed a lack of grasp of the subject which was truly elemental. Electricity was not a form of energy, but it was a condition of ether, or electrical fluid, in a state of stress or motion. The same critic also spoke of "producing" electricity, which was as impossible and absurd as producing matter.

In static electricity the electrical fluid, or ether, was in a state of stress or strain, like a thin rubber band stretched to its utmost. When the strain was relieved there was a disruptive discharge, as when the elastic band broke. According to another analogy, static electricity was like a thimbleful of water raised to an immense height. When spilled, it gathered such momentum in its fall that a severe blow was struck. If the thimble was continually filled, and as rapidly emptied, we had a succession of static discharges which formed an intermittant electrical current. The electro-motive force produced by the fall was immense, being over thirty-three thousand volts; but the resistance met was very great, and the quantity of the fluid was small, so that the total effect in current-strength was ordinarily not great.

A single disruptive discharge consisted of a principal discharge, or current from positive to negative, with numerous minor oscillations. The static current, so called, was one made of successive and infinitely brief discharges from positive to negative, with accompanying oscillatory discharges. The static current flowed chiefly from plus to minus, but contained numerous minor oscillations. It was a current of extremely brief components. By using small Leyden jars, which filled and discharged very quickly, this current could be made almost continuous, and would cause chemical effects. The intensity of current-strength was the amount of electricity passing through a given space in a second of time. The static discharge occupied such a fraction of a second that its intensity or current-strength was hardly measurable; but its voltage, or electro-motive, force was, as already stated, immense. The intermittent current produced was, therefore, a peculiar one.

Physiological Effects of Electricity.—As to its physiological effects, it contracted muscles powerfully. In experiments made five years ago, Dr. Dana said that he showed that applied percutaneously it contracted viscera in animals, and probably in man. With a continuous galvanic current passing through a degenerated muscle, a static spark or current caused a contraction. The muscular contractions caused by static electricity had been stated to be due to a purely mechanical effect, like that of a whip. This was, he thought, a wrong view, for the reason that the sparks caused contraction when applied directly to muscle, while in order that mechanical irritation should cause contraction of a whole muscle it was necessary that it should be applied at the motor point. Also, because there was no apparent mechanical irritation, in the ordinary sense, when the static current was applied with wet electrodes. In the case of the spark, there was a sudden expansion of the skin at the point of contact from heat, but no deep mechanical disturbance. The question was not an important one, however. At most, it must be said that the static spark acted like the secondary current of a faradic battery, causing no measurable electrotonic effects.

Static electricity was applied in the form of a disruptive discharge, a spark in the form of the bath and wind, and by the current. The effects of the spark were well enough known. The effects of the bath and electric breeze had been inadequately stated. When a person was on an insulated stool, and charged, a series of discharges was going on from all parts of the body. This produced a cutaneous stimulation and a mental effect. This cutaneous stimulation had in some cases a peculiar physiological æsthesic effect. It was by no means psychical. It was not necessarily reflex in the ordinary sense, but belonged to the same class of physiological phenomena as those of metals. The evidence that certain metals had æsthesiogenetic power was undoubted, and he had abundant clinical evidence that electricity could act similarly. This particular physiological effect of static electricity had not before been pointed out. The static current could be used with moist sponge-electrodes through the clothes, or with wet electrodes upon the skin. The current caused tonic contractions of the muscles. It was not a pure single-direction current, but the most powerful discharges were always at the same poles.

Therapeutic Uses of Electricity.—As to its therapeutic uses, the special advantage of the static battery was in paralyses, with some spastic element, as in hemiplegias and paraplegias. Aside from this, its best results were in chronic, muscular, rheumatic, and neuralgic conditions, and in many sensory disorders (Eulenberg and others). It had a specific æsthesiogenetic influence in certain cases producing effects in a way similar to metallo-therapy—not by mental influence or suggestion. It had practically a very great value in dispensary clinics, where a good many cases of paralysis had to be treated. In nervous clinics, with few patients and abundant medical attendance, the faradic and galvanic battery might answer, and this might explain the indifference to static electricity by some of its critics; but in large dispensaries he considered it almost a duty to patients to have a battery which insured a prompt and efficient electrical treatment in all cases. Our mastery of disease, he said, in conclusion, was not so great, or our means of attacking it so ample, that we could afford to ignore a single measure that would help us in the fight.

Static Electricity.—Dr. J. H. Gunning said that he was glad to hear Dr. Dana speak in such favorable terms of static electricity, as he could testify to the correctness of his views; and it was with this form of electricity that his experience had been the most extended. He spoke particularly of its good effects in facial paralysis, stating that, instead of the treatment extending over four or five months, as was the case, according to many critics, when the galvanic or faradic current was employed, under static electricity only as many weeks were often all that were required for a cure. The first patient whom he treated in this way was a well-known physician, a member of the New York Academy of Medicine, and in this case the recovery was accomplished in six weeks. He had also used this agent with success in paralysis of the lower extremities and various other forms of paralytic trouble.

Faradic Current.—As to the faradic current, he had had excellent results with it in gynecological practice, and particularly in its capacity as an emmenagogue and sedative. As an emmenagogue it had not infrequently proved efficient when all other methods of treatment had been tried in vain. In some cases of obstinate vomiting it had also proved of special service. He thought that one reason why electricity sometimes proved an unsatisfactory method of treatment was because it was not given with the same care and attention to details as was the case with other remedies.

Dr. Henry D. Chapin read a paper on "1, The Auriculo-ventricular (Presystolic) Sound; 2, Some Considerations on Cardiac Disease in Early Life" (see p. 4).

Dr. Andrew H. Smith said that he was not one of those who believe in the existence of a presystolic murmur as distinct from the diastolic, and having a mode of production and a significance of its own. There was a presystolic murmur, but it was only a continuation of the diastolic murmur, re-enforced by the contraction of the auricle. If the orifice was greatly narrowed, and especially if it was irregular, the flow of the blood through it would cause a sound during the ventricular diastole and before the auricular systole. If, on the other hand, the orifice was less contracted and less irregular, the blood would flow through it silently until its flow was hurried by the contraction of the auricle, when a murmur would be developed. This supplement to the diastolic murmur had no different significance from the latter, and he could see no good reason for giving it a special name. But there was a murmur which precedes the first sound of the heart (what Dr. Sansom called a before-first-sound murmur), which he believed was systolic, and not presystolic. It occurred in those conditions in which, from some general cause, the heart murmur is enfeebled, and the ventricle becomes temporarily dilated. The transverse diameter of the cavity is increased, and the length of the chordæ tendineæ measuring the same, the valve-curtains are held away from each other, until, in the progress of the systole, the normal diameter of the ventricle is reached, when they come together. To illustrate this, suppose the normal diameter of the distended ventricle to be represented by 4, and the combined length of the opposite chordæ tendineæ to be also 4. This permits the curtains to float together, and to come into coaptation at the first instant of systole. But suppose that the ventricular cavity becomes dilated until its diameter is 5. Now, the combined length of the chordæ tendineæ remaining 4, it is evident that at the beginning of the systole the curtains will not be able to float into contact, but will be held apart from each other a distance represented by 1. As the systole progresses they will approach each other, and when the diameter of the cavity is reduced to 4 they will meet, and the valvular sound will be produced. But, meantime, they have been prevented from performing their office, the orifice has not been closed, and blood has been flowing back into the auricle, and giving rise to a systolic murmur, which nevertheless preceded the first sound. Murmurs of this kind are transient, disappearing as the strength is restored, and the heart-muscle recovers its tone. His experience, Dr. Smith said, coincided with that of Dr. Chapin as regards the tolerance of cardiac disease in early life. He had seen children with severe endocarditis, accompanied by very marked valvular lesions, go on for years, apparently suffering but little inconvenience. He recalled especially the case of a boy, three and one-half years of age, who, eight years ago, had a systolic murmur so loud that it could be heard distinctly when the ear was two or three inches from the chest, and who had all along run and played with other boys, apparently in perfect health. This murmur was still there, though greatly reduced in intensity; but the unfavorable prognosis which he had given eight years ago seemed as far as ever from being verified.

Dr. W. H. Katzenbach said that he had recently had occasion to look up some statistics, and he had collected four hundred and twenty eight cases in which the left side of the heart was affected. In considering these he had been struck with the large number of cases of presystolic murmur met with in young women of from eighteen to twenty-eight years of age. It was surprising, he thought, to find how frequently this murmur exists without the presence of any symptoms; and this was the more remarkable from the fact that a considerable proportion of the cases occurred in servant-girls and others who took a great deal of active exercise. It was characteristic of this murmur that it often disappears and then reappears again. In many instances it would disappear when the patient took the recumbent posture, and come back again when an erect position was assumed. In others a moderate amount of exercise was required to make it appreciable to the auscultator. As to the prognosis, he had been astonished to find how well the condition was borne, not only by children, but by adults also. In conclusion, he called attention to one symptom frequently met with in mitral stenosis which he thought had not been sufficiently regarded, and that was bloody expectoration.

Presystolic Murmur.—Dr. Alfred L. Loomis said that he did not suppose that there was any doubt in the minds of auscultators at the present time as to the existence of a presystolic murmur. There was a time when the question of the reality of such a murmur might have been raised; but now he thought there could hardly be two sides to such a question. We had been accustomed to consider three classes of presystolic murmurs, viz.: 1, The hæmic; 2, the congenital; and, 3, those depending on chronic endocarditis.

In the first class of cases, as the blood-making power of the patient was recovered the murmur would disappear; and it would return again whenever conditions having an unfavorable effect upon this function occurred. This hæmic variety he had observed sometimes in connection with nervous phenomena in children. Congenital mitral stenosis he believed to be of not infrequent occurrence, and as an illustration of it he mentioned the case of three sisters, whose ages ranged from eight to sixteen years, whom he had seen when in charge, some years ago, of the class for diseases of the heart and lungs at the Demilt Dispensary. In each there was a very distinct presystolic murmur, with purring thrill and all the conditions necessary for the diagnosis of the condition in question. No cause could be ascertained for the existence of mitral stenosis, and there was no question in his mind that the trouble was congenital. Such a condition did not interfere particularly with the comfort of the individual. It was to be borne in mind that all heart-murmurs, as well as the ordinary sounds of the heart, were much louder and more diffuse in children than in adults, on account of the thinness of the chest-walls; and hence a murmur which might seem very terrible in a grown person ought not to be regarded with as much apprehension in the case of a child.

As to the presystolic murmur due to endocarditis, it seemed to him that no one who was accustomed to see these cases during life, and to observe the pathological conditions met with after death, could hesitate to acknowledge that the condition presented was sufficient to produce such a murmur, through the agency of the "buttonhole slit."

These murmurs were often independent of systolic murmurs, and sometimes were present in addition to the latter. As far as time was concerned, indeed, we might have a large number of murmurs, as the presystolic, the systolic, the post-systolic, the diastolic, and the post-diastolic. It seemed to him that while we were, and had been, accustomed to talk a great deal about cardiac murmurs, they were not really the essential element to be considered, were not really of practical significance. To be of importance they must be accompanied by changes in the cavities and walls of the heart and in other parts of the system, and this was especially true as regards mitral disease.

Rheumatic Children.—In children of a rheumatic habit endocarditis was very frequent, and it often occurred long before any evidence of rheumatism presented itself. It was, in fact, due to the same cause as the latter disease, and if treatment were resorted to sufficiently early the case might never go on to fully developed rheumatism. Although this point had not been referred to in the paper, the connection between endocarditis and pericarditis was also very close, and the latter often occurred in children. Dr. Loomis said that, so far as his experience went, aortic disease was not frequent in chil-

dren. Mitral disease was the variety commonly met with, and if nature provided sufficient compensation, a child affected with such trouble might go on to adult life without suffering any inconvenience.

Dr. H. N. Heinemann said that we must admit that both at the base and apex of the heart we get all sorts of hæmic murmurs. As he understood it, the object of the paper was the discussion of that particular form of mitral disease which is recognized by definite pathological lesions and accompanied by a distinct sign indicative and pathognomonic of it. He had recently collected a considerable number of statistics from the medical clinic at the College of Physicians and Surgeons, the Roosevelt Hospital, and other sources, and of the cases thus tabulated 153 were in children. Of the 153, thirty seventy-fifths were cases of mitral regurgitation, and twenty seventy-fifths of mitral obstruction; while the proportion of aortic affections numbered respectively only one seventy-fifth, two seventy-fifths, and three seventy-fifths. The observations of Dr. Loomis as to the comparative frequency of mitral lesions and infrequency of aortic lesions in children were thus confirmed by these statistics.

For the mitral presystolic murmur we had a satisfactory cause in over eighty per cent. of the cases in the infectious diseases. As to the symptoms accompanying this form of murmur, it had been his experience to find that in a large proportion of cases more or less præcardial pain was complained of. It was well known, too, that of all cardiac murmurs met with, the presystolic was most readily distinguished without applying the ear to the chest; so that it was often possible to make the diagnosis as soon as the ear was brought within two or three inches of the chest, although, of course, no auscultator would depend on this without making a direct examination. The bloody expectoration, to which attention had been called by Dr. Katzenbach, was also a valuable sign.

In conclusion, Dr. Heinemann stated that, according to his observations, the presystolic murmur in children often disappeared when adult life was reached, the mitral disease having developed into aortic trouble.

Dr. Edward G. Janeway said there could be no doubt that there was a presystolic murmur resulting from mitral stenosis; but, as Dr. Smith had remarked, it was diastolic as well as presystolic. For a long time some authorities hesitated to accept the existence of the presystolic murmur, their doubt being based on the supposition that the auricle has not sufficient force to produce such a murmur. It could be positively demonstrated, however, that in reality very little force was required for this purpose.

As regards the prognosis of mitral stenosis, he said that his experience had led him to take a less hopeful view of the condition than had been expressed in the paper, and by some of those who had taken part in the discussion. He had found that quite a number of cases died, and sometimes comparatively suddenly. In illustration he related the case of a young woman who died one hour after her admission to the hospital, the only lesion found after death being mitral stenosis.

The prognosis, however, was not to be based simply on the existence of the murmur, but rather on the condition of the cardiac valves and walls, as well as that of other organs, like the liver, lungs, kidneys, and spleen. Sometimes these patients did fairly well as long as they were free from other troubles; but if they became affected with any other disease, or condition, as anæmia, for instance, serious symptoms would at once make their appearance. It was a fact that well-to-do people, who had easy lives, lived much longer with mitral stenosis than those among the working-classes, whose active life necessitated more work for the heart to do.

Dr. J. Lewis Smith said that he had collected seventy-five cases of organic heart trouble in children from his service at the out-door department of Bellevue Hospital, the oldest of the patients being twelve or thirteen years of age. As to the etiology of the cardiac disease, in fifty-five it was directly attributable to rheumatism, and in five to scarlet fever. In twelve, the previous history of the child, so far as it could be ascertained, threw no light on the causation of the difficulty. He said that his experience coincided with that of others as to the comparative mildness of rheumatism in childhood, and it could not be doubted that there were a great many "walking cases" of the disease. Parents would state that their children had not complained of pain, or, if they did so, the circumstance was attributed to "growing pains," and regarded as a matter for congratulation, as indicating an increasing robustness of the constitution. So far from this being the case, however, such "growing pains" were too often the evidence of a condition which caused irreparable damage to the heart. The occurrence of rheumatism was thus frequently overlooked, and hence the opportunity was missed for the employment of treatment which would avert the impending danger of permanent cardiac disease. As pointed out by Dr. Loomis, an endocarditis might occur without the existence of rheumatism. He had met with a few such cases, and, as a rule, rheumatism made its appearance subsequently in their history.

Scarlet Fever.—As to the causative relation between scarlet fever and organic heart trouble, nothing definite was known at the present time; but it was an undoubted fact that in a certain proportion of cases of scarlatina what is known as scarlatinous rheumatism occurred about the second week of the disease. Endocarditis or pericarditis might also be met with.

Rheumatism.—Rheumatism was now regarded by many bacteriologists as a microbic disease, and it might be that the cardiac lesions were due to ptomaines produced by the rheumatic poison. Of the twelve cases of disease of the heart in which there was no assignable cause, he was inclined to believe that a considerable proportion were attributable to attacks of rheumatism which had entirely escaped notice.

Differential Diagnosis.—Dr. Smith then spoke of the differential diagnosis between true cardiac disease and malformation of the heart. He stated that some years ago he had collected from various sources some two hundred cases of the latter, and he had found that the malformation which was most frequently met with was an absence of the commencement of the pulmonary artery, or its obstruction or occlusion. He thought it not improbable that in a considerable number of instances we had to do with malformation rather than endocarditis. In the two hundred cases of malformation which he had examined he had met no record of congenital mitral stenosis, of which Dr. Loomis had spoken, and it seemed to him probable that in cases which appeared to be of this character the trouble was really due to malformation of the right side of the heart.

In the seventy-five cases spoken of the most frequent murmur met with was the mitral regurgitant, occurring in forty-seven instances. The next most common was the presystolic, while the aortic murmurs were the rarest. As to the matter of prognosis, it was his conviction that we are in the habit of regarding in too favorable a light these valvular lesions in childhood. In dispensary practice most of the cases are lost sight of in a comparatively short time; but he had found in private practice that in many cases dilatation and hypertrophy became developed in the course of two or three years, and subsequently the cardiac trouble terminated fatally. In only one instance, where he was able to follow the case along for six or eight years, did he meet with an embolism. It was perhaps worthy of note that in eighteen out of the seventy-five cases chorea was present, a fact going to substantiate the recognized causative relation between cardiac disease and this affection.

Dr. William H. Thomson said that it seemed to him strongly probable that the disappearance of presystolic murmurs, which had been well marked in early life, was in reality due to the supervention of other conditions. It was necessary to look beyond the murmurs, to look beyond the valves, to the vascular system. On account of the

normal condition of the arteries, children had a great advantage over older persons. The moment that arterial changes occurred, however, a direct effect was produced upon the heart, and the result was hypertrophy and dilatation of the left ventricle. Dilatation and regurgitation through the mitral orifice took the place of the mitral stenosis, so far as the murmur was concerned. Hence it could be seen how such a murmur would disappear by reason of the subsequent changes, the starting-point of which was arterial obstruction. It was a well-ascertained fact that in cases of mitral stenosis in early life the left ventricle was noticeably small; but if the children in whose cases autopsies were held had lived longer, it would have been found that the ventricle had become greatly enlarged.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, December 23, 1889.

ALEXANDER S. HUNTER, M.D., PRESIDENT, IN THE CHAIR.

The Treatment of Chronic Nasal Catarrh.— DR. O. B. DOUGLAS read a paper entitled, "Is the Cure of Chronic Nasal Catarrh as Difficult as has been Supposed?"

What Is a Cold?— After some preliminary remarks on the important position taken by the nose among the organs of the body, the author asked, What is a cold? And replied that we recognize a cold as the beginning of that condition which later became a chronic catarrh. Various theories had been advanced with regard to the process by which such results were brought about. He thought the following was near the truth: The heart, in its action, sent out a definite quantity of blood at each pulsation. At some point the capillaries refused to take their portion. Cold may have constricted their calibre, and this overplus had to be disposed of. Provision had been made for this when the erectile tissue of the turbinated bodies had been created. It accepted the surplus blood, and relieved the arterial capillaries, but itself became over-distended. Safety must be sought. The signal danger was sounded by sneezing, and we called it taking cold. Serum exuded from the cavernous tissue, swelling subsided, and respiration was relieved, or congestion remained and suppuration followed. This, however, was not the whole story. Other factors played their part, but the nose was the adjudicator, the balancer of blood-pressure, giving the danger signal when distant organs were not receiving their allowance of the circulating medium.

Chronic Catarrh.—He had not come with any wonderful and new catarrh cures. In fact, he had no new medicine or instrument to offer. Electricity in its various forces might be convenient, chromic acid was excellent, the nasal forceps, saw, etc., were useful; but skill and judgment were required as much as instruments and medicine. It was important, if possible, to remove the cause of the catarrh, particularly if it consisted of a pathological or abnormal anatomical condition of the nasal passages. Laryngitis, pharyngitis, tonsillitis, faucitis, conjunctivitis, otitis, etc., were all found in patients who had thickening of the middle or inferior turbinated bodies interfering with respiration, or other obstructions in the nose, and the author believed that catarrhal conditions resulted more frequently from these obstructions than from all other causes together. He did not mean occlusion of the passages necessarily. If there was contact, though slight but persistent, of surfaces not normally in contact with each other, one would find inflamed tissue beyond. Perhaps the most frequent obstructive cause was thickening of the middle turbinated body, with more or less pressure on the septum nasi. Secretions were retained, they became acrid, flowed down, and caused congestion and inflammation of the tissues beyond.

The patient complained that he was hoarse, secretions dropped into his throat, he had hawking, coughing, profuse expectoration, headache, ringing in the ears, poor appetite, eyes suffused, spells of sneezing, took cold on the slightest exposure, was nervous, felt feverish, and in general did not feel well. We looked at the tongue, found increased redness at the base, the uvula relaxed, elongated, the tonsils congested, enlarged, the glands inflamed, the lateral walls red and swollen, nasal pharynx generally inflamed, etc.; examination of the nose under the influence of cocaine—he used a ten per cent. solution—revealed possibly as a causative lesion hypertrophy of the middle turbinated pressing on the septum, or other deformity. This might be overcome with the trephine, or the actual cautery, or, in some cases, with chromic acid, or saw, or forceps. Dr. Douglas usually employed the forceps. It was not a difficult operation, but it was done better and easier after practice. One should take away sufficient tissue to free the passage, but was cautioned against unnecessary destruction of tissue. As in all surgery about the nose, there occurred at times more than an ordinary amount of shock. As stated, there were many forms of nasal obstruction, and it was possible that he had lain too much stress on hypertrophy of the middle turbinated. As long as the cause continued to act the results would certainly follow; catarrh was always more or less difficult to cure, and long perseverance was sometimes necessary, but it was not an incurable condition, and the worst cases were frequently those which recovered soonest, because the patients were thoroughly in earnest and were willing to pay the price of success.

The conclusions were: 1, The nose is not an unimportant organ, as some would suppose, but, physiologically and pathologically, is of first importance; 2, its position and functions expose it to injury and disease; variable temperature, chemical and mechanical irritants, as well as its normal functions perverted, tend to produce disease; 3, its diseases yield to appropriate treatment as certainly as those of any other complicated organ; 4, so-called catarrh is not a disease *per se*, but a symptom or result of other lesions; 5, chronic nasal catarrh is usually due to nasal obstruction; by this is meant not necessarily occlusion of the nostril, simply habitual contact of surfaces which are not normally in contact; 6, removal of the cause is always the first step toward cure, and this frequently requires surgical interference. Local and general medication are secondary, but by no means of slight importance; 7, the nose and its diseases are deserving of more attention from the general profession, because the consequence of neglect is far-reaching and serious; 8, chronic nasal catarrh is not as difficult to cure as I formerly supposed.

Operations for Stenosis.—DR. H. H. CURTIS said he could add but little to the subject, which had been presented so tersely and appropriately by Dr. Douglas. Regarding operations upon the nose for stenosis, he might say that he was unable to recall a case in which he had had any important [illegible]

the time when he was in Vienna, and witnessed Schroeder trying to replace the septum, or rejuvenate the mucous membrane of the turbinated bone by the use of gelatine suppositories, and persisting with the treatment three times a week for two and three years, and then looked upon the rapidity with which patients having the same nasal troubles were cured to-day, it seemed to him that we had made greater advance of recent years in the treatment of nasal diseases than any others. Even to-day, however, instruments were for sale in the shops which had been entirely discarded by those who kept pace with the advance in

rhinology, and pointed to the fact that there were some of the general profession whose treatment of nasal affections was little more scientific than that of the quack. He approved of the remarks of Dr. Douglas concerning the influence of hypertrophy of the middle turbinated in the production of nasal catarrh, and believed in some cases there was adhesion between the turbinated bones and the nasal septum. He here took out the entire turbinated bone, and found that in after-years the result of the treatment was very satisfactory. He had never seen an acute attack of gout precipitated by operations on the nose.

Dr. W. C. Phillips found himself in sympathy with the author of the paper. It was generally stated that chronic nasal catarrh was a result of repeated attacks of acute nasal catarrh. We were now confronted with the statement that it was generally the result of obstructive trouble in the nose, and this he believed to be true. Where obstruction from hypertrophy of the turbinated existed with catarrh, it should be removed, and personally he preferred the forceps for this purpose. In the large majority of cases it was the superior, not the inferior, turbinated bone which was hypertrophied. The patient should be kept in the operator's office, say two hours after the operation, instead of being sent home with a cotton pledget in the nose to prevent hemorrhage.

Catarrh a Form of Malnutrition.—Dr. Kitchen thought he must take somewhat the negative side of the subject as far as it had been discussed. He quite agreed with the author that chronic nasal catarrh was not so difficult to cure as was generally supposed, yet he was firmly of the opinion that the profession in general, and the specialists, had nothing to be proud of in this direction. There was no doubt that a certain number of cases could be cured by operative procedures, and he had done his share in the surgical direction, part of which he was ashamed of. The reason why we could not have better therapeutic success in diseases of the nose was the fact that we could not remove the causes. In the vast majority of cases where we operated, it was to remove the effects of the disease, not the cause. When one considered the usual causes, he would admit at once that a cure was often out of the question, simply because those causes could not, under present surroundings, be removed. Chronic nasal catarrh was, in his opinion, a form of malnutrition, as were many other diseases. We were living most unhygienic lives, and it was practically impossible to alter that mode of life in the majority of cases. A change to a correct mode of living and to a suitable climate, would cure most cases of chronic nasal catarrh where the cause was not due to hereditary malformation, traumatism, etc.; but how few people could so change their lives! When they continued in their former course, the specialist might afford some alleviation of the symptoms, but he could not cure the disease. We must not expect to accomplish the impossible.

Hypertrophied Turbinated Bones not always so Bad.

One Nostril Always Freer than the Other.—Dr. Beverley Robinson said he was not prepared to state anything new at all. With part of the discussion he agreed, with other parts he disagreed. He was disposed to think too much stress had been laid upon nasal stenosis and the necessity for surgical interference. Asking the gentlemen present to press first upon one side of the nose and then upon the other, breathing through each nostril alternately—those who could breathe through either side equally well, were requested to raise their hands. Very few hands went up. But nearly all raised their hands when asked if they could breathe through one nostril better than through the other. It followed that a certain amount of obstruction or deformity was not incompatible with health. But where this obstruction was a cause of nasal catarrh in the first place, or of its continuance, it should be removed. But there were other things to be taken into consideration which the specialists were too apt to overlook; such as those relating to food, air, diathesis, general hygiene.

Operations on Rhinologists.—Dr. W. F. Holcombe doubted whether there was a specialist in diseases of the nose present who would undergo the operations upon the nose to which he subjected his patients. He had himself suffered much from nasal troubles, yet as soon as he went to a high altitude in Colorado, his nasal symptoms disappeared. They returned when he came back to New York. Probably all patients called incurable would get better in a higher, dryer climate. Nasal catarrh was often due to reflex irritation from a distant part of the body, and would disappear with the cure of the latter. Those troubled with ethmoiditis had been much relieved by lying down and dropping a few drops of a four per cent. solution of cocaine into the nose (not spraying it in). Quiet the nervous condition, free the sufferer from pain, and the swelling of chronic nasal catarrh would diminish. He wouldn't give a cent for caustic applications.

Believed in Treating the General System.—Dr. Messenger said that he had tried to relieve patients with chronic catarrh of the mucous membrane of the nose and ethmoiditis, which had been incidentally mentioned in the discussion, and had succeeded; he believed also that Dr. Douglas, and others, had relieved their patients for a time, but he did not believe at all that they had effected a cure. Were they able to change the climate, the constitutional influences, the mode of life of their patients? He believed in treating the general system which gave most hope where it could be carried out. In the way of local treatment, nothing was better in his hands than a solution of salt or soda snuffed up the nose.

Dr. Douglas closed the discussion.

Correspondence.

OUR PARIS LETTER.

(From our Special Correspondent.)

THE CAUSE OF FEVER—ANTISEPTIC PROPERTIES OF LIME—CARE OF EYES OF SCHOOL CHILDREN—HEREDITY OF MYOPIA—THE STUDY OF TUBERCULOSIS.

Paris, December 6, 1889.

In a paper recently submitted to the Academy of Medicine, Dr. Roussy stated that fever is often the result of soluble, non-organic principles, but of microbian origin, being introduced into the animal economy. He has ascertained that injecting into the blood or under the skin water in which different organic matter has been macerated, also determines a febrile condition. He has isolated the pyrexogenic element, and concludes from the results of his experiments that certain diastases or zymoses (soluble ferments) have a febrile influence; the water in which the yeast of beer has been macerated is given as an instance.

Drs. Richard and Chantemesse have made a series of experiments published in the *Revue d'Hygiène*, relative to the antiseptic properties attributed to lime against the typhoidic bacillus and the cholera bacillus. According to these experiments, a solution of lime of the consistence of milk possesses properties superior to those of the chloride of lime and of corrosive sublimate, in the proportion in which they are habitually employed. The authors have disinfected fecal matters with this solution of lime, but only fecal matters in a liquid form can be so treated. When it is necessary to disinfect a cesspool in which the dejections of typhoid, choleraic, or dysenteric patients have been emptied, it is sufficient to pour a solution of lime into the cesspool. If the matters in it are in a state of putrefaction, it would be necessary to wait until, in the

first instance, the ammonia which the lime displaces from its saline combinations be disengaged, and in the next, until a portion of the lime be thus lost by disinfection. The liquid should be stirred with a wooden stick in order to facilitate the escape of the ammonia, and to render the mixture homogeneous.

Dr. Matais, of Angers, lately read a very interesting note at the Academy of Medicine on the hygiene of the sight in the schools of France. The author stated that in Germany, in Switzerland, and in some other countries, it was admitted as demonstrated that scholastic studies had a dangerous influence on the sight. Many medical men, however, considered that if myopia was so frequent in Germany, it was owing to a predisposition of race, and the absence of serious researches permitted one to affirm that this ocular affection was rare in France. Dr. Matais had examined 5,000 young subjects in the centre of France, and he found that myopia attained in the students of rhetoric, or of philosophy, the proportion of forty-six per cent. In Germany this proportion is fifty-seven per cent., and it is fifty per cent. in Switzerland. Thus it will be seen that the difference is not very great, and this is sufficient to admit that the causes of myopia in France are analogous to those of myopia in Germany. The influence of the school is otherwise established by the fact that, in the lower classes, myopia is almost completely absent; it rises to seventeen per cent. in the third class, and mounts to forty and forty-five per cent. in the classes of philosophy. Myopia is complicated in three-fourths of the cases of other ocular affections, often very grave, and the importance of remedying such a state of things may be well understood; and this can only be done by modifying the present system of hygiene in schools. To effect this, it is necessary that the pupils should work with a good light, seated on a bench placed near to the table receiving the light from the side, and preferably from the left side. The body should be kept straight, the writing should be straight, and the books should be printed with large new characters, and on yellow paper. The interruptions should be frequent during the hours of study, to which recommendation Dr. Matais attaches great importance. He shows that at the Military Prytanæum and at the School of Arts and Industry at Angers, myopia is relatively rare, although the hygiene is not better than in the colleges, because the interruptions in their work are frequent. At the school of Angers the studies are interrupted by manual work. At the Prytanæum, where the studies are well regulated, and they do not last more than an hour and a quarter, the recreations are passed in games or active exercises. Finally, Dr. Matais proposes that a service of inspection should be created, which would permit the oculist to examine the pupils and to prescribe opportune treatment, which would prevent divers ocular troubles.

At a previous meeting of the Academy, Dr. Matais read a note on the "Heredity of Myopia." The author had examined the familes of 330 young myopic subjects, and arrived at the following conclusions: 1. The hereditary influence of myopia is manifest. 2. It exists in 216 out of 330 families. 3. Hereditary myopia is characterized by its early appearance, its comparatively rapid development, and the high average of its degree. 4. Myopia is transmitted by the father to the daughter 86 times out of 100, and by the mother to the son 79 times out of 100. Heredity is crossed.

The second Congress for the study of tuberculosis will be held at the end of July, 1890, under the presidency of Professor Villemin. The following are the subjects pro-

should send their names with a postal order for 20 francs to the General Secretary, Dr. L. H. Petit, 11 Rue Monge, Paris.

ONCE MORE THE ACTING ASSISTANT SURGEON.

To the Editor of the Medical Record.

Sir: So far as I know the Acting Assistant Surgeons in actual service have been quiet since the last Congress adjourned. But some friends who had the push to get out while still young enough to fight for existence, have kindly taken up the fight which had been laid down by us. And here let me state that I have been requested to correct an error into which you fell in a late editorial. So far as I know, Acting Assistant Surgeons have never been subjected to examination further than to ascertain that they are graduates in regular medicine from recognized colleges, and are men of good character and correct habits.

I have just read the articles of Dr. Brodie, of Detroit, and Dr. Nagle, of New York, in your issue of November 30th, and fully agree with both. The Acting Assistant Surgeon is very like a weasel, and also very like a camel. Certainly he is at perfect liberty to resign if he does not like his position. But when the second lieutenant of infantry received the maximum pay of sixty dollars per month, and all others in proportion, they were at perfect liberty to resign, but very few availed themselves of it. Instead of resigning they worked steadily for more pay, until now the maximum pay of the army is: Second lieutenant of infantry, $163.33; of cavalry, $175; first lieutenants, $175 and $186.67; captains, $210 and $233.33; and so on to the end of the chapter. The staff corps are paid the same as cavalry. They also enjoy indefinite sick leave on full pay, or retirements on three-fourths of duty pay. There is not in all the world another class of men of the same average merit so bountifully provided for.

And yet, considering the nature of the service, and the fact that they forego all the prizes which tempt ambitious men in the world, their pay is none too much. But while this is true, Dr. Brodie might have added to the fact that the Government can get all the Acting Assistant Surgeons it wants at the present rate of pay, the further fact that Congress could reduce the present rate of army pay to $1,000, $1,200, $1,500, $1,800, $2,000, and $2,400—the latter being the pay of a colonel—in addition to incidental allowances, and still fill every position in the army with men of the same average ability as now. The clamor for civil positions is enough to prove this. Men would prefer the fixed to the doubtful tenure. But would such action be just or expedient on the part of Congress? I think not.

But there is no divinity which condescends to hedge about an Acting Assistant Surgeon. Some ten years ago, in the interest of the surplus, his pay was reduced from $1,500 to $1,200 per annum. He cannot get a leave, either for pleasure, business, or sickness, without forfeiting every cent of his pay for the time. Civilian clerks get a month annually on full pay. Commissioned officers get the same, with the privilege of accumulation for four years, when they can go for four months on full pay, and, perchance, a year more on half pay.

But we are not complaining. If we don't like our positions we can resign! We have been told that before.

All this agitation grew out of the cases of a few men who rendered service in the War of Secession, and have served more or less continuously since. The "army habit" got too deep a hold upon them, and they have gone on until too old to take the world by the horns, but still are haunted by the consciousness that even their present pittance is not secure against any caprice of politicians or others who may wish to urge young men for their places.

Let us suppose the case of one of the men responsible

Case II. is one of a tailor, twenty-seven years of age, thin and anæmic, who three and a half years before had contracted syphilis in the usual manner, and had shown the typical sequelæ. When received at the hospital in April, 1886, he showed none but the following florid

[1] Paper read before the German Medical Society of New York, November 4, 1889.

for this agitation. We will assume that he served three years, or four, as Regimental, Brigade, and Division Surgeon of Volunteers. He is mustered out, and enters civil practice, but in a few years finds the "army habit" asserting itself so strongly that he takes a contract, hoping for better to follow. He has served, let us say, twelve or twenty years on the plains, often in surgical charge of important posts and expeditions. In the course of events he is relieved of some post by a gentleman in uniform who is no way his superior in general culture or professional ability and experience, and who has rendered fewer years service than himself, but receives two and a third times his pay, besides all the other blessings which hedge about the army brass and blue. Now, if this old Acting Assistant Surgeon is very foolish and inconsiderate, he may growl and insinuate that he deserves better of his country. It is so easy for men to be self-conscious, and, instead of resigning, persuade themselves that their country is the party under obligation.

It was in this state of mind that, two years ago, about twenty of the ungrateful growlers contributed $350, and signed contingent obligations of a much larger amount, which they entrusted to one of their number who should lead an assault upon Congress for their betterment. There was no attempt made to bribe Congress, the fear of which justified some in withholding contributions, but the money was turned over as a retainer to a prominent Claim Agent in Washington who agreed to look after the interests of his employers.

The Acting Assistant Surgeon entrusted to lead the fight assailed Congress upon its head and not upon its pocket, with a respectful prayer, backed up with strong letters of endorsement from Generals Schofield, Crook, Stanley, Merritt, and Ruger, and possibly others. Result: A bill, introduced "by request," and after the fat was all fried out of it, a substitute was reported restoring our pay to $1,500 per annum, but was never called up for action. And why not! In all probability not one of the subscribers had voted since the war, and only one has been suspected of influencing a vote, so far as I know. And to avoid misapprehension, let the writer assert most positively that he is not the one suspected.

The gentleman who led the assault upon Congress has been urged to renew the fight, but has declined, because he believes that there is between him and Congress an impregnable barrier. All that he now seeks is to be "let alone," and allowed to die with the harness of a grateful country upon him.

Still, for the comfort of those who left us at the right time, and who have notions, I will state that my belief is that Acting Assistant Surgeons should be appointed by warrant; should be uniformed when on duty with troops; should have the same longevity increase of pay as commissioned officers; at least a month's pay annually on leave, if they want leave; and have the same forage and other allowances as Commissioned Surgeons. Why not?

S. S. Turner,
A. A. Surgeon, U.S.A.

* Three cases of suspected typhus fever have been sent to North Brothers Island Hospital for observation.

The Psychology of Living.—What may be described as the psychology of living is the mental state produced by the circumstances of life upon mankind. This condition varies largely not only with each individual person, but almost with each nation, and is, practically speaking, purely a matter of temperament. It is the nature of some persons always to be despondent, however much their surroundings may conduce to serenity of mind and to a favorable view of life. This despondency may not necessarily be due to any mental deficiency; it is oftentimes merely the reflex of a temperament which is as natural in its development as is the growth of an arm or leg. Neither does it necessarily lead to suicide, but when the circumstances of life happen to become somewhat more exacting and are deprived of their roseate hues, then the act of self-destruction is taken seriously into contemplation, and is often consummated. Such a person acts toward himself as in other ways he acts toward those with whom he comes in contact. He shuns a person whom he dislikes, and he claims to decide for himself whom his friends shall be. Similarly, he decides that he objects to living, and proceeds forthwith to destroy himself. It is impossible to believe for a moment that all suicidal acts are the outcome of mental aberration. There is no doubt Voltaire was right in holding that the possession of a large amount of courage was necessary before a person could take his own life. But so much is it the case that most suicidal acts are primarily dependent upon a naturally despondent temperament that it is quite possible to believe if every despondent person with no better prospects than Mr. Micawber were gifted with the sanguine impressions of that individual, we should quickly hear less of the illogical act of suicide, and less of the complaints of the burdens of life. A sanguine temperament is unquestionably a most valuable possession, and, moreover, a highly serviceable acquisition in furthering the aims of life and in advancing the interests of those to whom it belongs. Mr. Micawber was no impossible creation of the great novelist's mind; there are, happily, [illegible] which they are habitually employed. The authors have disinfected fecal matters with this solution of lime, but only fecal matters in a liquid form can be so treated. When it is necessary to disinfect a cesspool in which the dejections of typhoid, choleraic, or dysenteric patients have been emptied, it is sufficient to pour a solution of lime into the cesspool. If the matters in it are in a state of putrefaction, it would be necessary to wait until, in the

ON THE SUBCUTANEOUS GLANDULAR AFFECTIONS OF THE LATE STAGE OF SYPHILIS (GUMMOUS OR TERTIARY BUBO OR LYMPHOMA).[1]

BY SIGMUND LUSTGARTEN, M.D.,

NEW YORK.

SOME personal observations, which I have had the opportunity of making during the past few years, form the basis of the following communication. The chapter to which this subject belongs has not been sufficiently studied, and is not even mentioned in many of the leading works on surgery and syphilis, although, on the border-line between these two branches of medicine, it invites the study of both surgeon and syphilographer.

CASE I.—Male, aged thirty-six, driver, was received in Professor Kaposi's wards in February, 1885. The history concerning previous syphilitic affections is negative. For two years there has existed on the left side of the neck a tumor, which is sensitive on pressure, but rarely painful. Examination shows a waxy, pale coloration of the skin, and relaxation of the muscles. Internal organs normal. In the region of the left side of the neck is a tumor considerably larger than the fist, extending from the mastoid process along the line of the jaw and sterno- cleido-mastoid muscle, and reaching beyond the median line. The tumor is not movable in any direction, and is seen to be composed of nodes ranging in consistence from firm to soft, and, as it were, massed together. The boundary line above is sharply defined, but in the opposite direction is diffuse. At some points fluctuation can be felt. The skin overlying the tumor is in places movable, but for the most part is adherent; it is of normal color or slightly hyperæmic over the firm masses, and dark reddish, tense, and shiny over the softened areas. In the left supra-clavicular region there is to be found a second fluctuating tumor of the size of a walnut, also covered with dark red and very shiny skin. Indolent swelling of the inguinal glands of each side and of the left cubital region. Spleen normal.

Treatment.—Inunctions, Zittmann's decoction, potassium iodidi. As the tumor begins to decrease in size under the specific treatment, its composition becomes more striking, and it is seen to be made up of nodules of different ages, partially bound together by nodulous lymphatic vessels, the softened spots contract, and the fluctuation disappears. After eight weeks of treatment the patient was discharged, his general health was much improved, the tumors having decreased to fibrous indolent nodules the size of an almond or hazel-nut. He was ordered, during the following two months, to alternate each week between potass. iodat., 2.0 gm. a day, and hydrargyrum tannicum oxydulatum in daily dose of 0.2 gm., and to take Turkish baths.

CASE II. is one of a tailor, twenty-seven years of age, thin and anæmic, who three and a half years before had contracted syphilis in the usual manner, and had shown the typical sequelæ. When received at the hospital in April, 1886, he showed none but the following florid symptoms: In the right inguinal region an orange-sized tumor composed of conglomerate nodules up to the size of an English walnut, mostly of firm consistence. The tumor, which was fixed to the underlying tissues, was painful on pressure, and sometimes spontaneously so in the night. Over the summit of the tumor the skin was shiny, of a brownish-red color, and showed fluctuation. In other parts the skin is somewhat movable over the swelling. In the neighborhood the lymphatic glands are affected by scleradenitis in a mild degree, as also in all other palpable regions of the body. Treatment as in Case I., besides tonics and locally emplast. hydrarg.

Involution followed the regular course until, after six weeks of treatment, the patient was cured. Both these cases are types of uncomplicated isolated gummous lymphadenitis.

CASE III.—Differing in some respects from the foregoing was Case III., male, thirty-five years of age, pale and stout, who was recommended to me for surgical treatment by Professor Kaposi. Neither was the patient, who was weak-minded and a descendant of an old family, nor his travelling companion able to give any history of a previous attack of syphilis. Examination showed: Soft sore in the sulcus coronarius, and acute suppurating bubo, the size of an apple, in the right groin; internal organs normal, no signs of syphilis.

Treatment.—Free incision of the bubo, evacuation with a sharp spoon, and iodoform bandage. The course was normal until, in the fourth week, the necrotic parts were eliminated; the wound had taken a healthy action and the cavity was nearly closed, when the picture was suddenly changed. Without pain or fever, the base and surroundings of the wound became indurated, the wound spread open again, and the base appeared lardaceous and of grayish white color.

In spite of all therapeutical efforts, change of local applications, the use of tonics, etc., we had before us again, after three weeks, a firm, indolent, uneven bubo of the size of the fist. I could then not help thinking that metamorphosis *in situ* was due to a new pathological process complicating one already existing; in other words, to a sort of *mixed infection.* As neither the course nor any symptoms indicated scrofulosis or a malignant tumor, a gummous infiltration was thought of as the most probable explanation, and this was very soon proven, by the effect of specific treatment, to be the case. As soon as the latter was begun, involution also promptly commenced, the wound closed, and after three weeks an increased fibrous resistance alone indicated the former site of the lesion.

It is probable that in this case the previous bubo process had produced in the affected lymphatic glands a *pars minoris resistentiæ* in which, supposing a predisposition to exist, a syphilitic infiltration could easily develop. I shall be able to quote in the following pages similar cases from literature. The strikingly rapid involution in this case I would explain by the short duration of the gummous affection.

CASE IV. is one of a girl, aged eleven years, well developed, but a deaf-mute, whom I had the opportunity to examine, at a consultation in a Vienna hospital, in the spring of 1889. The patient, who suffered from nocturnal cephalalgias, showed an oblong, grayish-yellow, caseous tumor of the size of an egg in the left supra-clavicular region. The skin was wanting over its centre for a diameter of six centimetres, while the margin showed the

[1] Paper read before the German Medical Society of New York, November 4, 1889.

characteristics of a syphilitic infiltration, both in color, consistence, and other qualities. The glands in the neighborhood were firm and enlarged in a slight degree. Under a treatment of mercurial plaster and the iodide of potash a cure rapidly followed, as the house physician afterward told me, the headache disappearing and the general health improving.

Whether this case was one of syphilis hereditaria tarda, or one of acquired syphilis, I could not possibly decide, as all history was wanting and likewise all auxiliary aids, excepting, perhaps, the symptom of deaf-mutism, which is of very dubious value. This case is also interesting because it shows us that that form of caseous degeneration may take place in the subcutaneous glands which hitherto had been observed only in gumma of visceral glands.

I beg leave to give, as concisely as possible, a review of the literature of gummous lymphadenitis.

The first reported case is one by Potier, 1842, who described an instance in many respects similar to Case II. Salneuve, 1852, demonstrates the possibilty of tertiary adenitis. Des Ruelles, Sarrhos, Cahen, report single observations on adenitis in tertiary syphilis, which is also the theme Potain discusses in his thesis "Sur les Lésions des Ganglions viscéraux."

General attention was first called to the subject by the publications on "Constitutional Syphilis" by Virchow, and the well-known work upon "Syphilis" by Lancereaux. To the first-named fundamental work I shall repeatedly refer in the course of my remarks. Lancereaux, speaking only of the deep glands, says: "The study of the syphilitic alterations of these glands dates only from recent years. Swediaur acknowledges that in his time there existed not a single authentic observation of these lesions. To-day the deep tertiary adenopathy is anatomically better known than that of the superficial and subcutaneous glands. The reason for this is that there is given a much better opportunity for microscopical investigations." Most frequently the abdominal glands are diseased, and, secondly, the bronchial and mediastinal. He further says: "The affections of the (visceral) glands must be reckoned among the most frequent, and as showing the most constant alterations of tertiary syphilis. They bear the same relation to visceral syphilis that swelling of the subcutaneous glands bears to syphilis of the skin, *i.e.*, they are a necessary concomittance." From this time syphilis of visceral glands was acknowledged without any further opposition.

Verneuil saw in a male patient, after amputation of the leg, the development of a large firm tumor in the groin, which ulcerated; the ulceration extending to the deeper parts as well as to the surrounding surface, and by eroding the femoral artery, caused death from hemorrhage. Verneuil supposes the tumor to have been a gumma of the glands, developing in consequence of the previous surgical trauma. Two additional cases are published by Bourdon, under the auspices of the above observer, both females, with tumors of the glands in the inguinal regions who were cured or improved under the iodide of potassium.

At about the same time an important publication was given out by Campana, upon the swelling of glands in constitutional syphilis. Of the great number of cases which, with the exception of four, belong to the secondary stage, we will refer to the following one only: A female, infected ten years previously, presented an ulcerated gumma beneath the chin, two glands the size of a walnut upon the right side of the neck, and upon the left side an equally large fluctuating swelling, which, upon incision, poured out a small quantity of yellow fluid containing débris of tissue. Cure by iodide of potassium. Fournier also has observed a submaxillary tumor, coinciding with an ulcerating syphilis of the lip and jaw; and Homolle a supra clavicular adenitis, with a gumma of the tonsil and a gumma of the cubital gland, subsequent to a gummous skin eruption of the forearm. Furthermore, two out of the four observations of Virchow contain references to the affection of superficial glands.

Nearly all of the cases mentioned, as well as a number of those which follow, contain instances of gumma of glands complicating other tertiary processes. The observations of glands affected in an isolated manner are of more importance, but are much less frequently referred to (about twenty cases, including our own four observations above given). If the first group demonstrates by the complications the syphilitic nature of the affection, and removes every doubt of their existence, the second is of importance because it shows the difficulty of diagnosis in some cases, and the clinical resemblance to malignant tumor, and especially to malignant lymphomata.

Referring to the last-named affection, I quote from Homolle an observation of Birch-Hirschfeld, in which the gummous infiltration had invaded so great a number of glands that it was thought, until the post-mortem, to be a generalized malignant lymphoma; and a second case of lympho-sarcoma of Wunderlich, which Wagner interpreted to be a gumma of the glands.

Mauriac, in 1878, signalized the similarity of certain gummata of the glands with chancroidal buboes, and mentions three cases in which suppurating buboes of rather acute development had transformed themselves into serpiginous ulcerations. The acute course in these cases makes it probable to me that here, as in Case III., which I have above cited, there was a syphilitic infiltration subsequent to acute suppuration (possibly produced by blennorrhagia).

Gonnet publishes two observations of Fournier and Besnier, respectively: one, a male, with ulcerating syphilis of the lip and submaxillary glandular gummata; the other, a female, who, after ulceration of the face and nose, with perforation of the palate, showed gummata on the supra-clavicular glands. Ramage gives three observations from Fournier's clinic, of ulcerous gummata of the inguinal and submaxillary glands in undoubted syphilitic persons, and from Quinquaud and Fay, each one case of gummous clavicular and cervical glands, respectively.

In an important work on gummy tumors, Langenbeck, 1881, reports the following case: A female, forty-two years of age, who gave a rather dubious history of syphilis, showed in the right groin, below Poupart's ligament, a very painful, rounded, firm tumor, the size of a fist, fixed to the underlying tissue, and with an uneven surface. The diagnosis of the neoplasm, which had been growing during a period of six months, lay between carcinoma and sarcoma. On account of scar-like callous concretions, the operation of removal proved so difficult that part of the tumor which enveloped the vessel was left behind. The extirpated mass was declared, after microscopical examination by Langenbeck and Virchow, to be a gumma. The patient succumbed to pyæmia.

A further case of Langenbeck should probably be classed with these. In a female, aged fifty-three, there was a tumor painful to the touch, of the size of an egg, upon the right side of the neck. The diagnosis of carcinoma was made, and the new-growth excised. As in the former case, numerous firm concretions rendered the operation difficult, and made necessary the extirpation of the jugular vein at the same time. The tumor proved to be a granuloma, and Langenbeck had still less doubt that he had operated on a gumma since two years later the patient suffered a relapse and showed specific ulcerations of the tongue and palate. Had the latter manifestations of the disease not occurred, probably this instructive case, as I dare say many others, would be still in doubt. Langenbeck, being at that time at the very summit of his clinical experience, cannot forbear to observe, on the same article: "It would be of the greatest importance to find some means of recognizing gummy tumors with certainty, a thing which will be so much the more difficult, because characteristic features are in many respects lacking; and we must unfortunately acknowledge that neither the external appearances of the tumor nor the concomitant subjective and objective symptoms will prevent mistakes of diagnosis. To this must be added that not even the macroscopical

and microscopical appearances of the extirpated growth have at all times such characteristic qualities as to exclude errors with certainty. "Pathological anatomists advance similar views. Thus Virchow (on tumors) states that the differentiation of granular tumors from sarcoma is very hard, and that they might be considered a subdivision of sarcomas, to the small-celled variety of which they bear a close connection. In the ante-bacterial period the appellation scrofulous sarcoma was commonly employed. Ziegler says: "There are not rarely formations of tissue to be seen which suggest new-growths, and it is often difficult to decide by microscopical examination whether lymphatic glands enlarged to the size of a tumor should be ranked among the neoplasms or as inflammatory or hypertrophic exuberances. The decision here is rather oftener dependent upon the clinical course of the tumor in question, which is known from experience, than on the histological examination."

After this short digression, let us return to our theme. Cunningham refers, under the title, "Case of Supposed Lymphadenoma," to a male patient, thirty-five years of age, who had an enormous tumor extending from the middle of the neck on the right side to a point several inches below the nipple, while on the left side the glands were enlarged. McCall Anderson, the eminent clinician of Glasgow, whose advice was asked on this case, thought that it might possibly be syphilitic, and ordered kali iodatum, which, indeed, had so striking an effect that the syphilitic nature of the affection could no longer be doubted. Cooper reports briefly the case of a male, whose supra-clavicular regions were both filled with large, soft glands. The pale and cachectic patient was undoubtedly syphilitic, and a cure was effected under a specific treatment. Furthermore, Lannois and Lemoine describe the two following interesting instances: A male, thirty-four years of age, who had four years previously acquired syphilis, developed in the right groin a firm tumor of the size of an orange, painful to the touch, which subsequently softened and suppurated. In the further course of the disease the process extended to the femoral vein, and caused phlegmasia alba dolens. Under a specific treatment the patient recovered after two months and a half. A female, nineteen years of age, vigorous but anæmic, with syphilis of three years' standing, showed very firm and slightly painful tumors in both groins, some reaching the size of English walnuts. Cure under mixed treatment. My friend Lannois has quoted my above-reported Cases Nos. I. and II., the latter of which I had the pleasure of demonstrating to him during his stay in Vienna, while I informed him of the former case by oral communication. I have also previously written upon the present question in the article "Bubo," in Villaret's "Dictionary of Medicine," and I there put forward as a fourth form of bubo the "gummous or tertiary bubo."

Lastly Esmarch, in an important discourse (on the etiology and diagnosis of malignant growths), delivered at the Surgical Congress of last year in Berlin, states, from his own experience, though without citing special cases, the existence of tertiary syphilitic lymphatic tumors. The speaker is positive that a great part of the new-growths, which are generally called sarcomata and extirpated, belong in reality to the syphilomata. "A syphiloma may remain as a tumor during many years without increasing. If syphilomata are extirpated, relapse very soon occurs, together with all other symptoms of malignancy." The above remarks apply especially to tumors of the lip and tongue, but we are justified in applying to glandular gumma what in general is stated in regard to syphiloma. Esmarch goes so far—too far, in my opinion—as to advance the hypothesis that in many cases the development of tumors, especially of sarcoma, has a connection with a disposition inherited from syphilitic progenitors.

Before constructing a clinical picture from the material presented, some points deserve special attention.

In our own Cases Nos. I. to III., as well as in some observed by others, there has been noted a marked anæmia of greater or less intensity. I have no doubt that there is a connection between this and the disease of the glands, though not characteristic of the original process. It is well known that in affections of the numerous lymphatic glands, paleness, chloranæmia, troubles of digestion, etc., as a general rule show themselves. In one group, to insist upon one chief feature alone, the blood is found to be much richer in lymphatic cells at the expense of the red blood-corpuscles (leucæmia and leucocythosis in syphilis). In another group the blood is found impoverished in its formed elements, hæmoglobin and dissolved albuminous substances—oligæmia (pseudo-leucæmia, glandular affections in syphilis, scrofulosis, etc.). In both cases the consecutive disorder of assimilation and respiration may lead to a sort of cachexia and marasmus. Between the two forms transitions may also be observed, and it is very probable that, as Virchow has already supposed, mechanical factors may at the same time be at work. Supposing the hypertrophic glands to be in activity, and the channels leading from them to be free, the blood will be overcharged with lymphoid cells; on the other hand, and which is more frequently the case, if the productivity of the glands is interfered with by necrobiosis or by reason of obstructions in the lymphatic ways, in such manner that the cells are crowded in the hypertrophic tissue, then the formation of white blood-corpuscles is retarded.

Those features are of much importance in a clinical sense, because they may give to a comparatively benign process, as in the present instance to syphilis, provided that it attacks lymphatic glands, the character of malignancy (leucæmia, pseudo-leucæmia).

Concerning the course of subcutaneous gummous adenitis, it corresponds to the schema which Virchow has marked out for gumma in general. According to this we distinguish three stages: (1) Stage of simple irritation. The intercellular substance remains gelatinous and preserves a certain coherence. Similarity to hypertrophic course. (2) Medullary stage. The proliferation of cells prevails, the intercellular substance softens, the mass of the tumor breaks down, with pus formation. Similarity to heteroplastic processes, like medullary carcinoma and sarcoma. A number of the histories quoted in this paper illustrate the propositions just made also for gumma of glands. Finally, (3) the caseous stage. The cell-proliferation is but little abundant, the intercellular substance increases, the cells preserve the character of connective-tissue or granulation cells, fatty degeneration takes place, and results in the formation of a dry yellow node of the internal organs. Of this form we have only one instance in Case IV. above cited. This pathologico-anatomical scheme elucidates and completes in a clear manner that which the clinical course suggests, and it is of much importance to bear it in mind, because it points out the erroneous ways in which the diagnosis may lead.

Now let us review the clinical features.

Of subcutaneous glands, tertiary syphilis attacks most frequently the inguinal, secondly the glands of the neck, especially the submaxillary and intra-clavicular (Cunningham, Langenbeck, Homolle, Cases I. and IV. above cited, etc.); much more rarely the cervical, axillary (Cunningham), and the cubital glands (Homolle).[1]

Rarely a single gland is affected (Langenbeck, our Case IV.); in the rule one chain of glands, or the glands of one or several regions (Cunningham, our above Case I.).

The diseased glands present themselves as roundish, oval, firm, elastic, at times hard, tumors of uneven nodular surface (Cooper alone reports soft tumors), or they appear as masses softening in the centre and possibly fluctuating, or they may appear caseous. The two forms

[1] It may be that the relative frequency of implication of the inguinal glands is only apparent, being less often overlooked. The mental association between inguinal bubo and syphilis is even more firmly established than that between syphilis and other glands. Still it may be that the inguinal glands, which in the early stage of syphilis in genital infection are the most implicated, also show more frequent relapses in the tertiary stage.

first named are often found associated, and observation demonstrates that the second form is evolved more or less rapidly from the first.

The size of these lymphomata varies from a cherry to that of an orange, most of them being of English walnut size.

The glands are in general indolent or somewhat sensitive to the touch; sometimes, especially during the night, a dull or lancinating pain may be felt. The occurrence of excessive pain, such as is common in malignant neoplasms, is rare (case of Langenbeck).

The gummous lymphomata appear in the beginning movable upon one another and upon the underlying tissue. After a longer duration firm cicatricial-like tissue is formed which fixes the glands to one another and binds them to the parts beneath, extending into the septa of the fascias, and enveloping the vessels and nerves in such a manner that operation for their removal may present very great difficulties. In some cases glands more or less distant from each other are seen to be connected by nodular lymphatic bands of the size of a quill.

The skin over many of the glands is movable and remains so, while over others it is coextensive with the capsule. If then the gland softens or becomes caseous, the skin is mostly involved. It becomes infiltrated, and successively red, brownish, or livid. Then, after the capsule of the gland is perforated, the skin becomes thin and shows, at least when ruptured, a mellagenous, viscous mass which contains débris of tissue, or the mass is more puriform and of a grayish-yellow color. More rarely the skin becomes gangrenous and is exfoliated over a diameter of several centimetres, and shows a characteristic syphilitic ulceration of the gland, or one which has become caseous. In other cases the process extends after the perforation to the skin, and causes an extensive serpiginous, ulcerating syphilide (Verneuil, Mauriac). The latter course forms an interesting analogy with lupus vulgaris, developing at times in the skin over scrofulous glands, especially at the point of perforation of the skin.

The tertiary lymphadenitis presents itself (1) concomitant with, or subsequent to, other syphilitic lesions (Virchow, v., vi., xi.; Campana, i., ii., iii.; Gonnet, etc.). At the same time visceral affections may be present. (2) In a predisposed individual, subsequent to surgical or other traumas; or in glands which a previous disease has rendered a *pars minoris resistentiæ* (Verneuil, our Case III., and possibly Mauriac's cases). (3) As single manifestation of the disease (Potier, Verneuil, Bourdon, Cunningham, Cooper, Langenbeck, Wagner, Birch-Hirschfeld, our above Cases I.–III.).

The affection develops and runs its course in general in a chronic manner. The lymphomata may persist during many months, and even more than two years, as hard tumors, though more frequently, after several months duration, single tumors become softened. As is generally the case in tertiary syphilis, the power of spontaneous cure is very slight or totally wanting.

In the beginning of the affection leucocythosis has been observed (Virchow). If the disease is of longer standing and many glands are implicated, the symptoms of a more or less marked oligæmia (chloranæmia) may make their appearance and lead to cachexia.

The age of the affected individuals varies from eleven to fifty-three years, being most frequently found in the third and fourth decennium.[1]

A suitable antisyphilitic treatment brought about a cure in all the cases.

A glance at what has preceded will show that the affection with which we are occupied presents a great similarity in a number of clinical aspects with several other processes. Here also the Proteus-like nature of syphilis is manifest in its imitation of other morbid conditions.

[1] As the disposition, in the first and second decennium of life, to affections of the lymphatic system is well known, the fact that so few observations are reported at this period suggests that the affection is often confounded with scrofulosis.

On the whole, it must be said that tertiary lymphomata will often be properly recognized if, after all, we bear more constantly in mind the possibility of their existence. In which case it may also happen that one will see shades of difference which have an important bearing on diagnosis, and which may be more readily perceived than described, or made understandable to others. In all dubious cases the old rule of experience holds good: *In aubiis suspice luem.*

To touch only upon the question of differential diagnosis—for in the present state of our knowledge it is not possible to exhaust it—it is observed that glandular gumma, when a single gland is affected, may be confounded with primary carcinoma or sarcoma (in a restricted sense) of the glands, enchondroma, scrofulosis, actinomycosis. Sarcoma, in general, will be differentiated among other things by its rapid growth, enchondroma by its very slow development and great firmness, whereas the great rarity of primary glandular carcinoma, in dubious cases, will lead to the supposition of gumma. In scrofulosis, that is to say, tuberculosis, there is, besides the differences of course, complications, color, etc., the theoretical difference shown by bacteriological examination. I use the term "theoretical" because in practice the demonstration of bacilli in glandular pus often does not succeed, and experiments on animals are not always easily carried out; and for the further reason, that unless the latter are made with all the precautions of modern bacteriological technique, they will more than ever give rise to misleading diagnosis. On the other hand, actinomycosis will readily be excluded by demonstration of its characteristic microorganisms.[1]

If many glands are attacked, there come into consideration the primary simple hypertrophies, an affection not elucidated, which is especially described by older French authors as frequently occurring in the army; the scrofulous, that is to say, tuberculous glands; the leucæmic tumors, which, in addition to the examination of the blood, are further characterized by their extension in a flat manner and by softness; and the malignant lymphomata (pseudo-leucæmia, Hodgkin's disease). Although in respect to the latter the gummous lymphomata are characterized in general by greater inclination to softening and ulceration, and by a more slow and benign course; yet the above-quoted cases of Wunderlich, Birch-Hirschfeld, Cunningham, and even our Case I., demonstrate how difficult diagnosis may sometimes be.

If the glandular gummata are secondary to, or followed by, other symptoms of syphilis, there will be no difficulties encountered in forming a just estimate of the process.

In all dubious cases the diagnosis must be determined *e juvantibus*, and this so much the quicker as the possibility of degeneration (more properly called a complication) of gummata which have not been treated for a long time, into malignant tumors, must not be lost sight of. The injury which an uncalled-for specific treatment may produce is without importance in comparison with the beneficial therapeutical effect secured when the contrary is the case.

The treatment should be an energetic one, in preference a mixed treatment of mercurial inunctions and potassium iodidi, together with the administration, during several weeks, of Zittmann's decoction. After the disappearance of the symptoms excitation of assimilation and excretions by warm baths, Russian baths, massage, etc., and alternating weekly the internal use of iodate of potassium and mercury; besides dietetic measures, tonics, etc., according to the indications of each individual case.

Finally, let me say a word in regard to the designation "gummous or tertiary lymphoma," which is employed in the title and again several times in the text. It is desirable that it should be adopted, on practical grounds. Patho-

[1] Till now there exist no bacterioscopic examinations of glandular gumma; the reason being that by far the greater number of the cases have been observed in the ante-bacterial epoch, and that, upon the whole, the opportunity for microscopical examination is rare.

logical anatomy, it is true, defines lymphoma as a new growth having the character of lymphatic tissue. On the other hand, the designation "lymphoma," with the appropriate epitheton added, has been applied to purely hyperplastic or to chronic inflammatory processes, which in a clinical sense have the appearance of new-growths (leucæmic malignant lymphoma). It is in analogy with the latter to add tertiary syphilitic affections of the glands to lymphomata, and it is to be hoped that in consequence—by connecting the latter name with the suffix of lues—one will be aided in the proper recognition of the affection which I have described.

THE PHYSICIAN'S PROPRIETARY ARTICLES, OR UNIFORM PREPARATIONS FOR OUR PHARMACOPŒIA—WHICH?[1]

BY H. H. RUSBY, M.D.,

NEWARK, N. J.

IF any of you, reading the announcement of this discussion, have attended under the impression that commonplace facts or pleasing generalities concerning our Pharmacopœia are to be brought forward, I beg at the outset to assure you that such is not my intention. The facts which we are to consider are not commonplace, and some of the generalities are, unfortunately, anything but pleasing. I ask your most earnest attention to certain considerations of the utmost importance to your success and to the welfare of the public whom you represent. Among the hundreds of subjects which will command the attention of the next Revising Convention—all of more or less general interest to us—one or two surpass all the others in importance. They underlie our success as practising physicians, decide annually the question of life or death for thousands of patients, ought to have been taken up and settled long ago, and present no hope of being thus taken up and settled until their discussion shall be undertaken by such bodies as your own. These are sufficient reasons why everyone present should take a peculiar and active interest in this discussion.

It is very generally claimed and admitted that the interest of physicians in the Pharmacopœia has declined, while that of pharmacists has correspondingly increased. If the interests represented by these two bodies were identical, such negligence on our part might be overlooked. But they are not. Not only are the relations of the pharmacist to the patient not such as to impress him fully with the result of pharmacopœial dictums, but his personal interests are in certain ways directly opposed to our welfare and to that of our patients. It is apparent that the pharmacist is a pecuniary gainer by the continuation of a looseness and an indefiniteness in official requirements. It is true that he ought, under such circumstances, to lay aside selfish considerations and conform his action to scientific and humanitarian standards. And so, in many cases, he does; but I fear that to a great extent such is not the case, as will be indicated by the following extract from the report of the Committee of the New York State Pharmaceutical Association on Adulteration:

"Of dilute acetic acid 15 samples were examined, the strength ranging from 1.9 to 26.8, only two being alike. How can it be possible," asks the committee, "for a doctor ever to be sure of his dose when the same prescription will in one store bring fourteen times more than in another? Seven samples of spirit of nitrous ether varied so greatly that the patient would need to take about a pint of one to equal a teaspoonful of another. Of 50 samples of Hoffmann's anodyne only 8 were of good quality, and only 5 others were even fair. Of 17 samples of iodide of potassium none came up to the pharmacopœial standard, and only 7 could be accounted fair. Of 40 samples of crocus, United States Pharmacopœia, not one contained any crocus at all. Out of 48 samples of precipitated sulphur only 18 were good, while a large number were positively dangerous." Almost all the other articles examined showed similar shocking imperfections.

This, gentlemen, is an official report, unwillingly rendered, it is to be presumed, by a committee upon the action of its confrères, and may therefore be considered as thoroughly trustworthy. I cannot believe that the situation is so bad in all States as it is in New York. I firmly believe, for instance, that a less bad state of affairs would be found to exist in the State of Pennsylvania. But, on the other hand, there can be no doubt that in seventy-five per cent. of our States the condition of things would be found even worse than that which I have here described. The illustration is quite sufficient to sustain my claim that in a large number of instances the pharmacists in active business in our country at large will concern themselves but little in reference to the quality of the goods which they handle, so long as we shall allow them to profit by neglecting such attention. So it is necessary that we should make, through the medium of the Pharmacopœia, and vigorously enforce upon them, our demands in those matters which materially affect the success of our efforts in combating disease. To two of these matters I shall confine my remarks.

I wish first to call your attention to the fact that it has been proposed, by a majority of the Committee of Revision, to introduce into the Pharmacopœia the protected article Antipyrin.[1] As regards the propriety of prescribing so useful and important a substance, there can scarcely be a negative vote. But the full significance of the introduction into the Pharmacopœia of so fully protected an article should not be lost sight of. The question of right in this case is one of extreme difficulty, and it is possible that it may at length be decided affirmatively; but if so, it should be only after the most thorough consideration and the freest discussion, and, being finally decided upon, the action should be taken in such a manner as to free it from its natural tendency toward opening the door to an official recognition of all manner of objectionable proprietary articles. If introduced, it should be only under some carefully framed proviso specifying the conditions which determine the action, and carefully limiting its effect as a precedent. Under no circumstances should the name Antipyrin be printed, either as the official name or as a synonym. Either the entire chemical name of the substance should alone be used, or an abbreviation of it should be coined for the occasion and duly advertised. It is a matter of some difficulty to induce physicians gener-

[1] Read before the Philadelphia County Medical Society, December 11, 1889.

[1] It should be noted that this proposition on the part of the committee was made in good faith. It seemed to them desirable that this important question should be discussed, and they took this method of promoting such discussion. At the same time, they were not fully informed as to the degree and character of protection which applied to the substance.

ally to discriminate between the different forms of protection in drugs and medicines. The ordinary patent insures to its beneficiary a monopoly for a limited time, and fully provides for the publicity and freedom of manufacture at the end of such time. Many of our ablest and most ethical members believe that it is both just and expedient that such privilege should be accorded the inventor in medicine and surgery, the same as in the mechanical arts. But the registering of a trade-mark gives to its owner a monopoly for all time, and places the question of supply and its regulation absolutely and forever at his pleasure. A trade-mark of this nature, which affords perpetual protection in the manufacture of an article, is not to be confounded with the perfectly justifiable trade-mark indicating the origin of an article. Thus a firm may select and register for its trade-mark the sign of an anchor, a seal, a combination of letters, or other device, designed solely to guarantee to itself the credit and to assume the responsibility for the quality of all goods bearing that mark. But a protecting trade-mark which is the name of a substance prevents anyone else from applying such name to the substances as manufactured or produced by them. Thus the owner of the trade-mark "Sulfonal," a foreigner, by the way, having registered the same under our laws, is forever freed from competition, either as to price or quality. He may become more avaricious with age, and impose upon consumers such a price as shall place the substance out of the reach of all but the wealthy. He may grow careless, and in the future supply a product comparatively useless, or even dangerous. Yet we have no redress. As in the case of antipyrin, the process by which it is produced is patented, the product as a product is patented, and the name under which it is known is trade-marked. Such a possibility is opposed to every principle of justice, humanity, expediency, and even good law. Our laws permitting it should be modified at the earliest moment, and, preceding such modification, every member of your delegation should plant himself firmly against the recognition by the United States Pharmacopœia of any trade-marked name, whatever may be decided in reference to the substance itself. Merely calling your attention to this point in passing, I leave it to be more fully discussed by your next speaker.

The second subject to be treated is of far more practical every-day importance to us, as it points to a defect in pharmaceutical preparations upon which depend nearly all the failures in medical treatment which do not proceed from the actual ignorance of the practitioner or the carelessness of the patient.

One of the most chilling and disheartening influences to which the student and the young practitioner are subjected is the want of faith by the older practitioners in the efficacy of drugs, and particularly of those of vegetable origin. This scepticism, either real or professed, is so wide-spread as to be almost general. But I believe that it results almost wholly from defects in the preparations of the drugs. Given perfect pharmaceutical preparations, and I believe that a want of faith in the reasonable certainty of medication should be construed as an indication of unfitness on the part of its author. And the attainment of such perfection, in the case of many of our most important pharmacopœial preparations, is not only possible but eminently practicable. My text will be found in this statement: *Adherence to the present directions of the Pharmacopœia for the preparation of fluid extracts and similar preparations insures no degree of uniformity.*

Which one of you who has practised physiological experiment would not deride the physiologist who would administer an experimental dose of the strength of which he did not have an idea which approached nearer than within two hundred or three hundred per cent.? If the distinguished physiologist of the University of Pennsylvania, or he of the Jefferson Medical College, were to read a paper on the action of some new alkaloid in which he should inform you that certain symptoms had succeeded the administration of one, or two, or three centigrammes, or thereabout, what an audible smile would go up from every part of this room; and yet you, when administering to your patient a uniform measure of a pharmacopœial preparation, are doing just exactly this thing. The dose which your patient at Tenth and Walnut Streets is receiving in a drachm of a given tincture may be two or three—yes, even six or eight—times as strong as that with which you are treating him at Nineteenth and Race Streets. Not only, gentlemen, do I say it may be so, but I tell you that it is more likely so than otherwise. I doubt if you, as a class, are well aware of the irregularity in strength of the preparations ordinarily dispensed at the prescription counter. The Pharmacopœia prescribes that for the manufacture of a pound of the fluid-extract coca, a pound of coca-leaves shall be used. If, instead of this, it directed that any amount from one to three pounds were to be used, according to the inclination of the pharmacist, what would you think of its value as an authority? Tell me, then, what is the difference between using one to three pounds, and using a single pound whose strength is allowed to vary between one and three hundred per cent.! It is certainly true that a pharmacopœial rule for the manufacture of fluid-extract jaborandi, for instance, by the use of a specified amount of leaves of a strength ranging between the ratios of one and three, is strongly, totally, effectually antagonistic to the efforts of the physician in treating the disease to which it is applied. I hold that, if such direction were to read, "from one to three pounds of leaves, according to their strength," such direction, however indefinite and absurd it might be, would be infinitely superior, in the results which it would produce, to the directions as they now stand. However ignorant any pharmacist may be as to the effect of the administration by a physician to a dozen patients of a dozen doses supposed to be equal, but in reality varying widely, it is positively certain that a competent physician is not at all ignorant upon this point. And certain it is, also, that that portion of pharmacists who are contending for the right to compel the physician to work with such dangerous preparations at his own risk, the pharmacist himself being protected by pharmacopœial permission, ought to secure nothing else than the hostility of such physicians. But, you ask, do our ordinary crude drugs vary to any such extent? I doubt if there are more than a dozen persons before me who have any approximate conception of the wide variation in quality and strength of the drugs from which the preparations of the Pharmacopœia proceed.

Two conditions of such variation confront us. The first I have already indicated in the tendency on the part of a great many practising pharmacists to work with the cheaper article, when—as is usually the case—money is to be made by so doing. Through this lack of principle alone, hundreds of tons of drugs are annually used which are nearly—perhaps absolutely—inert. Let me read another extract confirming my statements concerning the unscrupulous nature of many pharmacists. Commenting on a sale of drugs which took place in London on June 30th, the *Chemist and Druggist* says: "Cumin-seeds at 5s., gum elemin at 3s., and Curaçoa aloes at 16s. per hundredweight were only a few of the unparalleled bargains. There were jaborandi-leaves that might profitably have been passed through a wringing-machine; 40 bales of senna at $\frac{1}{32}$ of a penny per pound; areca-nuts at 1s. per hundredweight; and, finally, 66 pounds of scammony at 3d. per pound."

These drugs, gentlemen, were purchased by pharmacists for the purpose of being made up into pharmaceutical preparations; and there is not the slightest reason why a portion of them should not have been dispensed upon the prescriptions of some of you. Will you not, then, see to it that the proceeds of a similar sale in June, 1890, shall not find their way into the hands of your patients.

Secondly, we have to consider that many pharmacists who are disposed to deal honestly are careless, or even incompetent, in selecting the better of two samples.

. Lastly, and the clinching argument in the discussion, be the pharmacist ever so honest, capable, and careful, it is in many cases an absolute impossibility for him to ascertain, from its appearance, the imperfection of a given sample. We cannot, and we need not, here consider in detail the conditions on which such variations depend. But I will mention that I have myself demonstrated that in the case of coca-leaves very wide variations in strength are caused by age of plant, degree of maturity of leaf when picked, soil, altitude, and mode of drying, all resulting in variations which it is very difficult or impossible to determine by the physical examination of the sample.

I have here prepared a list showing the degree of variation in some of our most important drugs, with the average strength which ought always to be secured. It is to be understood that these strengths refer to samples which on inspection would be pronounced upon the market good. If we were to include in the consideration the large amounts—constituting perhaps a majority of the total annual consumption—of crude drugs which are classed as inferior, this variation would be greatly increased.

Aconitum varies in the ratio of 3 to 5 or 6. Belladona-leaves, $\frac{2}{10}$ to $\frac{1}{10}$ per cent., or a variation of 250 per cent., with an average of $\frac{4}{10}$ per cent.; in this case it is to be noted that the poorest and the best leaves were absolutely identical in appearance. It is also to be noted that such vast differences are very generally caused simply by the quality of the weather during the season when the leaves were produced. Colchicum root, .4 to .52; colchicum-seeds, .5 to .9—average, .7; conium, exceedingly variable—average, .6; coca-leaves, .33 to .8—average, .6; nux vomica, 2 to 3 per cent.—average, 2½ per cent.; stramonium-leaves, .25 to .45—average, .35; stramonium-seed, .3 to .65—average, 45. Jaborandi-leaves (where uniformity is of the highest conceivable importance) show the wide variation between .3 and 1.1 of pilocarpine, with an average of .75. Cantharides, the powdered varying greatly owing to adulteration—average, .7.

In considering the above substances we are enabled to take cognizance of some definite chemical principle upon which the action of the drug chiefly depends, and which, by chemical or physiological methods may be readily estimated. There is another class of preparations, represented by zanthoxylum, buchu; and cannabis indica, where uniformity is highly desirable but cannot be secured by the estimation of such definite bodies. In many of these cases, however, we are enabled, by estimating the percentage of extractive matter yielded by some specified process, to arrive very closely at the relative strength of the drug.

Now I have said enough, I am sure, to convince you of the gravest want of uniformity in our preparations as at present defined. Considering the importance of the medicinal agents which I have named, and the extreme value of getting your patient promptly under their influence, I do not see how you can fail to be startled by observing the manner in which your best efforts are handicapped. At present your only guide to the strength of a preparation lies in its trial, and by the time you have established your dose your case may be lost. Yet you must thus establish your dose for each of your druggists, and every time he changes his stock—a sheer impossibility.

Am I not safe in saying that a medical practice which has no more reliable basis than our present method of supply is not better than semi-barbarous? Do not wonder, gentlemen, at the great number of failures which attend your treatment, and the irregular results which follow the administration of your medicine, but, when you remember that in a row of fifty consecutive drug-stores the same preparation exists in forty different strengths, ranging from twenty-five to one hundred and fifty per cent., wonder, on the other hand, that you have done one-half so well as you have, and never permit anyone to say in your presence that medication at its best is unreliable or uncertain. Let us take the lesson to heart and resolve that, as the remedy for the evil is so close at hand, we will apply it, and render in the year 1890 a greater service to medicine than has resulted from any convention which has preceded it. A long step may be taken at once, and if it be taken vast progress will follow in the next ten years. If this step be not taken in 1890, perhaps if you do not act to-day, the year 1900 may find us in the same disgraceful position that we now occupy.

Do not wait for your pharmaceutical brethren to institute this reform. Many of them stand ready and eager to help you. But for the most part they see a hundred lions in the way. While some of these lions may be fierce and strong, it is not for us to contemplate the situation. We are informed that not all our drugs admit of assay; but let us assay such of them as we can, and hope and work for such a knowledge of the remainder as shall shortly bring them within the same category. The pharmacist tells us that it does not pay him to assay his drugs for the preparation of the small lots that he is to manufacture; but what is that to us? It means simply that it is inconvenient for him to do justice to us and to our trusting patients. As well might the highwayman plead against a law forbidding murder because it will deprive him of an easy opportunity for transferring $3,000 to his purse. The pharmacist, gentlemen, is the caterer to our profession, and it is our business to make all reasonable demands upon him, and his business to concede those demands, or to stand aside and let another who is willing, for of such there is an abundance. The plea of the practical pharmacist in this matter is based upon the assumption that the primary object and design of medicine and pharmacy are for his emolument! We, on the other hand, have always recognized that it is the relief of suffering mankind, and that considerations of gain are secondary and incidental. But the use of these uncertain and irregular preparations is annually bringing bereavement and desolation to great numbers of homes. Looking upon the facts nakedly, we can only see that the position which we are here condemning is one whose virtual, however unintentional, object is the destruction of human life. This being true, we are led to inquire upon what claim the justice of such recommendation is based. Merely this—and I challenge any of my hearers to bring forward in plain and concise language any other—it is inconvenient at the present time for pharmacists to satisfy the requirements of justice and humanity. When we have once reduced the argument to this, we shall not combat it, but leave it to die the death which its shamelessness must invoke. If it is really true that after half a century of such a pharmaceutical education as our country has afforded, and which has brought the profession here confessedly to rank first in the world, our pharmacists are incompetent to assay a few preparations after specified formulæ, then the fact is a most disgraceful one, and there is not the slightest hope that after another half-century the case will be markedly different. But, emphatically, it is *not* true. If it be once admitted—which no well-informed person can deny—that one drug, for instance, if you please, erythroxylon, varies, in the strength of well-appearing commercial samples, between the ratios of one and two, that is to say, to the extent of one-hundred per cent., and that our present method of preparing a fluid extract allows this wide variation to appear in the preparation, we ask nothing more. If, thereupon, the medical profession and all decent pharmacists do not insist that this element of irregularity shall be eliminated, then do I entirely mistake the American character.

Progress does not require that we should go more rapidly than prudence shall dictate. But when it has been proven that coca, belladonna, and jaborandi leaves of good appearance vary widely in medicinal power, and that in the case of these particular drugs regulation of the strength of their preparations is perfectly feasible, we do not see how there can be any honest objection raised to taking this step in the case of those specific articles. Let the other hundreds of pharmacopœial substances

stand on their merits. If it be proven that three or six or twenty or only one substance admits of thus being taken out of the category of possible death-dealing or death-permitting agents and placed among the certainly life-saving ones, let it be done; and at a succeeding revision let as many others be added as shall by that time have been brought within the permissible circle.

Furthermore, the claim of the pharmacist that he must thus assay each of his small lots is false in itself. Assayed whole or powdered drugs are now offered by responsible dealers, so that the retail pharmacist may readily purchase 1 or 100 pounds of a given drug of known strength.

Our advice to the physicians who shall assemble at Washington next May for the revision of our Pharmacopœia is, that they shall solidly demand and persistently insist that something shall be done by that convention in the direction here indicated. Furthermore, and what is more to the point, we fully expect that this action is to be taken, and that this demand on the part of physicians is to be ably supported by the best and most powerful element in American pharmacy.

AN OPERATION FOR CORRECTING DEVIATION AND THICKENING OF THE CARTILAGINOUS NASAL SEPTUM.

By JONATHAN WRIGHT, M.D.,

BROOKLYN, N. Y.

The variety of operations proposed and performed for the correction of deviations of the cartilaginous nasal septum is very great. This, as usual, is due to the fact that no one operation is applicable to every case, nor is there any operation which is entirely devoid of objections. The solution of the problem at first sight seems an easy one, but it is really far otherwise. The exceedingly limited space in which operative procedures must be carried out, the impossibility of keeping the field clear of blood, the difficulty of etherization if general anæsthesia is resorted to, the restlessness of the patient and the shock to his nervous system if cocaine alone is used, in addition to the operation itself, all combine to try the surgeon's ingenuity to the utmost.

It is the exception to find a straight cartilaginous septum. It is nearly always deviated to one side or the other—more frequently to the left. Local thickenings when excessive are dignified by the name of ecchondroses, and are quite as frequently met with as deviations. Of course the nasal fossa toward which the deviation occurs is narrowed by the convexity of the curve, and the opposite side is correspondingly enlarged by its concavity. This deviation may be either in a horizontal or in a vertical direction, and is frequently a combination of both. At the angle, or rather at the most salient part of the convexity, there is always a thickening of the distorted cartilage, so that there is a redundancy of tissue not only from the curve of the septum but also from its thickening.

The degree of stenosis thus produced varies, of course, from the slightest narrowing to complete occlusion. The degree of stenosis which indicates the advisability of operation ought to depend entirely upon the patient's symptoms. As a matter of fact, however, the question of operation depends largely upon the personal bias of the adviser and the readiness of the patient to follow the advice given. Probably not one-half the number of operations are now performed upon the septum that were undertaken two years ago with the greatest alacrity. The difficulty of the operation is an excuse for the failures to correct the deformity; but frequently, when this has been accomplished, the symptoms for which it was performed have remained unrelieved, and this is due to a mistake on the operator's part in the selection of his case. It cannot be too strongly urged that every hypertrophic rhinitis, post-nasal catarrh, enlarged tonsil, or chronic laryngitis does not depend upon the deviation or ecchondrosis of the septum which may coexist. That such sequelæ often do hang upon a septal deformity is too evident for discussion. It is also true that extreme deviation of the septum and nearly complete occlusion of one nostril may exist with comparative freedom from any resultant obstructive symptoms.

The question of operating, therefore, must in each case be left to the judgment and conscience of the surgeon.

The object of all the operations proposed is the same—to obtain room for the passage of air through the stenosed nostril. This I have succeeded in accomplishing by removing enough of the redundant cartilage from the convex side of the septum to make it perfectly pliable at the point of its greatest convexity. The septum is then pushed over toward the free nostril and held in position by means of plugs until healing has occurred. Reference to the very complete review of the subject in Bosworth's latest work on the nose is enough to show that it is only the method of accomplishing this object which has even the feeblest claim to originality.

After cocainization and illumination of the parts, the thickness of the septum at the point where it most projects into the stenosed nostril is carefully made out, and the length of the deviation in an antero-posterior direction. A nasal trephine, operated by an electric motor, is used to make a hole from the anterior to the posterior surface of the deviation in such a manner that it goes as close to the mucous membrane of the concave side as possible without perforating it. This gives a little round tunnel through the substance of the thickened cartilage in an antero-posterior direction, beginning and ending in the stenosed fossa. A Bosworth nasal saw, or, better, an electric saw, is inserted into this tunnel, and so used as to separate the outer segment from the inner by sawing upward and downward, keeping as close to the middle line as possible, and thus taking a large portion of the thickened cartilage from the convexity.

The trephining is the work of a second, and is usually entirely bloodless, and with cocaine is nearly painless. The reason for this preliminary use of the trephine is that not only can a considerable portion of cartilage be taken away, but it is possible in this way to go very close to the concave side of the septum without perforation, and it thus makes a groove in which to start the saw. If a saw is used from the start, neither can the work be so accurately done, nor is it possible to make the septum thin enough. The sawing, if by hand, is slower, more painful, and very bloody. Although I have never used one, the electric nasal saw would no doubt greatly facilitate this part of it.

In the diagram the trephine entrance is seen at A, and the dotted lines indicate the direction of the saw above and below. It is evident that this procedure is applicable to a deviation either in a horizontal or in a vertical direction.

The septum should now be found pliable on pressure with the probe. In wedging it over toward the other side I have used absorbent cotton plugs soaked in sublimate solution (1 to 5,000), and renewed daily or every other day. Thick rubber drainage-tubing or Gleitsmann's tupelo dilators might be used for the same purpose.

The after-treatment is, of course, very important. Careful daily cleansing of the parts with an antiseptic

solution should be attended to for several days. Shreds of tissue should be cut away with the scissors; any small protuberance should be burned down with the galvanocautery. The wedging process and the antiseptic douching should be continued until the septum has been firmly fixed in its new position. If the septum has been sufficiently thinned down, the swelling which follows the operation should not cause excessive pain to attend the renewal and retention of the cotton or other plugs. I have never performed this operation by the flap method, though, of course, this could be resorted to as well here as in the ordinary operation; but it would render it longer and more difficult, and I doubt if any great advantage would ensue, as I am inclined to think that the granulation and cicatrization in themselves tend to draw the septum toward a straight line.[1]

As my experience with deformities of the septum which require a straightening of the deviation is limited, I have described the above procedure in the hopes that others will give it a trial, and refute or confirm my favorable experience with it.

MEDICAL CASES IN THE COURTS.

By HENRY A. RILEY, Esq.,
NEW YORK.

Unchastity Must be Proved in Defence for Slander.—In an Indiana court there was recently an action for slander, based on the alleged publication that the plaintiff, who was unmarried, was unchaste, and had become pregnant. It was further stated that she had committed an abortion on herself. The defendant applied to the court to issue an order requiring the plaintiff to submit her person to a medical examination, for the purpose of furnishing evidence to sustain the defence. The order was refused, and on appeal the decision was sustained as follows: "We are not cited to any case where any court has held such an examination to be proper, and we think none can be found. One should not publish and circulate slanderous charges against a young, unmarried female, as proven in this case, without being able to substantiate them, when called upon to do so, without calling upon the court to aid in the search for evidence in his behalf by ordering and subjecting her to an indelicate examination of her person, with the hope of obtaining some information advantageous to the defence, and call to his aid the power of the court as a means of humiliating her still more.

"When one voluntarily asserts a slanderous charge against another, and defends by alleging the truth of his assertion, he must be able to substantiate the truth of the charge, without invading the privacy of the person about whom the charge is made. The court very properly refused to make the order requiring the plaintiff to submit her person to an examination."

A Proof of Insanity.—In Arkansas the courts seem to hold that insanity, as a defence in murder cases, must rest on the inability to distinguish between right and wrong. If the accused was conscious of the act and its consequences, he must have been, by reason of insanity, wrought up to a frenzy, rendering him incapable of controlling his actions. If reason was dethroned, temporarily, merely by passion or revenge, the accused could not thereby be shielded from the consequences of his criminal act.

The facts of the case at bar were as follows: Defendant when a child received a wound on the head, which was followed by a fever—the result, in the opinion of medical experts, being to render him liable, in case of exciting causes, to an attack of insanity. He had been moral, quiet, chaste, and religiously inclined until after his acquaintance with deceased, who led him astray, and with whom he was criminally intimate; he was nervous, and would act strangely, wanting in stability, possessed of personal pride to extreme vanity, with great regard to the opinion of others. He had been arrested with deceased upon a charge of larceny, and was laboring under great excitement, exhibiting distortion in facial expression, and on the same day he went to the room of deceased, locked the door, and shot her and then himself. When he was seized he attempted to shoot himself again, exhibiting extraordinary strength.

On his person was found a telegram, ready to be sent, announcing his death, and another paper in his handwriting, stating, that having lost the respect of all, he had lost all, and that this was the cause of his "rash act," having determined to end his life with the one beloved. Upon this testimony, medical witnesses gave their opinion, that, if true, defendant was insane, incapable of reasoning correctly, and so completely deprived of the control of his mental faculties as not to know that what he was doing was wrong. The verdict in the case was guilty of murder in the second degree, and this was sustained on appeal.

Practicing Without a Certificate.—The question of not permitting a person to practice medicine without a certificate from the examining board has been under consideration in Iowa, and the wisdom of such a law seems to be clearly shown. The law stated that continuous practice for not less than five years was to be considered a *prima facie* qualification but that a certificate could be refused any person convicted of a felony, or it could revoke a certificate for a like cause, or for palpable evidence of incompetency.

The Board of Examiners declined to issue a certificate in one instance on the ground of incompetency, and the right to take such action was the matter before the appellate court for decision. The law was upheld as a requirement, and the decision, which is of much interest, is in part as follows: "We think the legislative purpose is best subserved by holding that the Board, upon the application of the defendant, had the right to inquire as to his incompetency, and that the established fact of his prior practice was no more than equivalent to the possession of a certificate, which might be overcome by a showing of palpable incompetency. The defendant, in his testimony, denies having been examined before the Board as to competency, but his testimony in this respect is conclusively overcome by the record. His examination, as shown by the abstract of appellant is brief, and in these words: 'Dr. S. Mosher was sworn; said his name was Sidney Mosher; that he was fifty-two years of age; says he began reading medicine in New York State when twenty years old with Kelly & Robinson, near Batavia. Never attended lectures; been in the practice about twenty years; began treatment of medicine before the war; began in Iowa, when Government first required revenue tax; said he did a general practice; did but little surgery; could not say how many cavities there were in the heart; cannot give the origin or insertion of any one muscle in the body. Select any one? Said he could not answer now, as he was not prepared to be examined. Can you give the therapeutic action of any single drug, and you select the drug? Could not say.' The examination discloses that the defendant was either palpably incompetent, or stubbornly silent, in either of which cases he had no grounds for complaint as to the action of the Board. If he knew, and would not tell, the Board was justified by his misconduct in believing him incompetent. If he did not know, the result is a vindication of the law."

Contributory Negligence.—A very important branch of law is termed contributory negligence, which means that a person cannot recover damages for an injury when he himself was negligent, even though the railroad company or some other means of harm was also negligent.

It has long been a question of dispute whether the same rule applied to a little child, who, though negligent, did not know that he was so, or could not devise means to escape the consequences. In such cases many courts have decided that the negligence of the child was imputable to the parent, and would prevent the latter from re-

[1] I have never seen the remark made in literature, but I have certainly noticed that much more than the usual proportion of straight septa are found in cases of atrophic rhinitis.

covering for the injury on the ground that the parent was in duty obliged to look after the child and keep him out of dangerous places. This rule has been declared in New York, Massachusetts, Minnesota, Illinois, California, Missouri, and other States. The opposite rule allowing a recovery has been established in Ohio, Nebraska, Texas, Pennsylvania, Connecticut, etc. One of the latest decisions of the latter kind is in Iowa, where the Court says: "In this case the child was taken into the wagon, and exposed to the accident which resulted in his death without volition on his part. He certainly was free from fault. If his parents, by their negligence, contributed to his death, that does not seem to us to be a sufficient reason for denying his estate relief. Such negligence would prevent a recovery by the parents in their own right. But it appears to us unjust and contrary to reason to hold that the irresponsible child should be responsible for the wrongful acts of his parents or others who may have him in charge. He is incapable by himself of committing any act of negligence, and cannot authorize another to commit one."

Valid Trust for Support of Horses and Hounds.—The English Chancery Division has recently decided that it is a perfectly valid trust to leave money for the support and maintenance of horses and hounds. The will gave £750 to trustees to use the income for fifty years in maintaining the said stables and in providing a home for the faithful horses and dogs.

Christian Science.—The Christian Scientists seem to be running foul of the courts. In Brooklyn recently several practitioners of the school were sent to jail in default of paying a fine on account of violating the law in regard to the spread of contagious diseases, and in a number of places the newspapers state that public sentiment would warrant criminal actions for malpractice and neglect of the patients. Clairvoyants do not escape actions for malpractice on the ground that their system does not require knowledge of anatomy or of the nature of diseases, and Christian Scientists and Faith Healers cannot hope to avoid responsibility for the failure to administer medicine, on the plea that prayer or mental treatment is the only method of practice with them. The Brooklyn Faith Healers regard themselves as martyrs, and do not seem to object to punishment.

THE GLYCOGENIC FUNCTION OF THE LIVER AND ITS RELATION TO ANIMAL HEAT, FEVER, AND DIABETES MELLITUS.

By GUSTAVE MAHÉ, A.M., M.D.,

NEW YORK.

"FEVER is a peculiar condition of the system in which there are present the phenomena of rise of temperature, quickened circulation, and disordered secretion."

The human body needs, for the proper physiological performance of its functions, a certain definite amount of heat. This amount is sufficient to keep the average temperature at about 98.5° F. At that temperature the various physiological functions are satisfactorily performed. When the heat-generating apparatus, through various influences to be hereafter discussed, produces an additional amount of heat, the temperature rises, reaching, in extreme cases, 108° and 109° F. At such high temperatures pathological conditions occur which are highly injurious to human life. Fever in itself is not a disease, it is a consequence of various maladies. It may be of the simple variety, a sudden elevation of temperature, lasting but a short while, and as abrupt in its disappearance as it was in its inception. Such a fever involves no permanent pathological or organic change, being due to such conditions as quickened cardiac action, over-activity of the glycogenic function of the liver, peculiar but temporary nervous conditions. Fever, as a rule, however, is not simple, it accompanies other ills, and, producing its high temperature, enhances the ravages of the mother disease. This fact is so well known to the medical profession that almost our first act, when called to the patient's bedside, is to take the temperature, and if it is found more than a degree above normal, medication to reduce it is immediately begun. This is done irrespective of the disease of which the fever is an accompaniment. It is unnecessary to state that we do not omit to direct other remedies at the cause of the fever, but neither do we fail to administer an antipyretic. In order to understand the phenomenon of fever, it is necessary to give a brief sketch of the theory of the production of animal heat.

Blood, average temperature, 98.5° F.; hottest in the hepatic vein, where it reaches 107° F. Heat of the body due to the combustion within it of human sugar, or glycogen. Glycogen decomposed in the body into alcohol and carbonic acid. Alcohol undergoes decomposition, uniting with the oxygen of the blood to form water and carbon dioxide, generating animal heat. Liver generates glycogen, therefore it is the heat-generating organ of the body. Liver, in health, generates glycogen from the carbohydrates, taken as food and introduced into the circulation as glucose. Carbo-hydrates contain carbon, oxygen, and hydrogen in the proportion to form water. When from any cause the carbo-hydrates are no longer supplied to the liver, it seizes upon and converts the fats into glycogen, finally attacking the nitrogenized principles until, finally, when the patient's weight becomes reduced about four-tenths, the individual dies.

The quantity of animal heat depends upon the amount of glycogen poured into the circulation by the liver through the hepatic vein, and its perfect or imperfect consumption in the system. The quantity of glycogen produced by a healthy liver is dependent upon two things:

I. Upon the amount of blood forced through the liver; and,

II. Upon the degree of activity of its glycogenic-forming cells.

The amount of blood forced through the liver depends upon:

I. The force of the heart's action.

II. The amount of resistance offered to the entrance of the blood into the portal circulation, and the greater or less directness of its course in reaching it.

The degree of activity of the glycogenic-forming cells depends upon the amount of controlling influence exerted over them by the right pneumogastric nerve. This influence is probably an inhibitory one, similar to that of the left pneumogastric over the heart-muscle. That the pneumogastric presides over the glycogenic function of the liver is proved by the fact that when its origin in the brain at the floor of the fourth ventricle is injured, by puncture with a sharp instrument, there is an immediate stimulation of the glycogenic cells, an over-abundance of glycogen is produced, it is eliminated by the kidneys, passes out in the urine, and we have diabetes mellitus. This irritation of the floor of the fourth ventricle can be produced in various ways: By certain drugs, such as ether, chloroform, etc.; by traumatic injury; by pathological changes at the spot itself. If the injury or irritation be only temporary, this over-activity will disappear after a time. If the lesion, however, be permanent, then the over-activity of the glycogenic cells becomes also permanent. The liver seizes upon the sugars, fats, nitrogenized substances, converting them into glycogen, until the patient dies from exhaustion, or the cells themselves may be destroyed by overwork, death ultimately closing the scene. Space does not allow here to treat of the intercurrent maladies which occur, such as phthisis, Bright's disease, colliquative diarrhœa, and in which the simultaneous injury to the other filaments of the pneumogastric nerve going to the lungs, kidneys, and intestines, plays an important part.

That diabetes mellitus is always due to an injury of the floor of the fourth ventricle is not true. This injury is not necessary to the existence of the disease. Repeated autopsies have revealed lesions only in a certain proportion

of cases. I farther on offer another cause for glycosuria. If the amount of sugar in excess, instead of being thrown off by the kidneys, be consumed in the system, it would produce an extra amount of heat; hence, instead of diabetes, we would have fever. This intimate association of two great pathological conditions opens up a large field of investigation which will doubtless lead to great results.

If, however, the controlling action of the pneumogastric nerve over the liver is normal, the cells are not over-active; they merely convert into glycogen the saccharine constituents of the blood, storing them up and distributing them *pro re nata*. If we increase the quantity of saccharine constituents of the blood by an excessive consumption of carbo-hydrates, we will increase the quantity of glycogen poured into the circulation. If the amount of blood forced through the liver is increased, the quantity of glycogen formed will naturally be greater. This increase in the amount of blood poured in the portal circulation has already been stated to be possible from two causes: Increase of the general circulation, and increase in the portal circulation. The first proposition is self-evident; the perception of the second requires a few anatomical details.

The blood entering the liver from which glycogen is normally formed is venous blood, entering by the portal vein, emerging by the hepatic vein, which empties its contents into the inferior vena cava; from this vein it enters the right auricle, which throws it into the right ventricle, thence through the pulmonary artery passing to the lungs, and so on. The liver also receives a comparatively small amount of arterial blood through the hepatic artery. The venous blood entering through the portal vein in health is the only supply concerned in the formation of glycogen. When, however, there is a deficiency of blood-supply to the portal system, through obstruction or otherwise, then a certain amount of glycogen may be formed by the cells directly from the arterial supply. The portal system is formed by the union of the superior and inferior mesenteric, gastric, and splenic veins, which collect the blood from the digestive viscera, and, joining each other behind the head of the pancreas, form the portal vein. Now let us begin at another point. The arterial blood, passing out of the left ventricle of the heart, enters the aorta, a certain portion being forced into the cœliac axis formed by the gastric, hepatic, and splenic arteries. As the names of these various vessels imply, they, in a general way, supply the stomach, liver, and spleen, a large number of anastomosing branches being given off from them, and going to form a complete net-work around the stomach. The blood, having passed through the stomachic substance in a minute capillary system, and having in its course therein taken up certain constituents of the food, forces its way into the gastric and thence into the portal vein.

Farther down on the aorta the arterial blood passes into the superior and inferior mesenteric arteries, which are distributed to the intestines, forming their main blood-supply; those two arteries have also anastomosing branches. In the intestinal walls the arterial blood circulates in an immensely rich capillary plexus, absorbing here again constituents of the food, and finally emptying into the superior and inferior mesenteric veins. A great many anatomical details I have, of course, passed over. It is sufficient, for the purposes of this paper, that we describe in a general way the portal circulation; and we have so far traced the blood entering it from the mesenteric and gastric veins. We have observed that these veins bring to the liver the assimilated contents of the stomach and intestines. We have found that the blood-circulation must be naturally slow. This sluggishness is due to the resistance offered by the length of the channels and the extreme minuteness of the capillaries. The only remaining one for us to consider is the splenic vein, and our chain will be complete. The splenic vein conveys to the portal vein alone the blood which has passed through the spleen. A few radicles from the pancreas are of no interest here. The blood going to the spleen is supplied by the splenic artery alone. The splenic artery is of large calibre, enters the body of the spleen by four or five large branches, gives off numerous ramifications, finally entering the splenic capillary system and passing into the vein. Hence it will be seen that the course of the blood is direct, and the only resistance to its passage in large quantities from the aorta to the liver is offered by the splenic substance itself. In its normal condition the spleen is contracted, squeezing down and compressing the calibre of its own vessels, and preventing an over-rapid passage of the blood through it. Now if, through any cause, the spleen relaxes, the calibre of the vessels would naturally become largely increased. An inordinate amount of blood is forced directly into the portal circulation. This increases the amount of glycogen formed by the liver, and we have it introduced in over-abundance into the circulation. But in the blood-supply entering the portal vein through the splenic vein there are neither carbo-hydrates nor fats. Very true. The glycogenic cells will have to fall back upon the nitrogenized constituents of the blood for their material; and so they do, appropriating the necessary elements and casting off the nitrogen in the shape of urea, which is increased. As a clinical fact, it has been observed that urea is increased in all fevers, except, perhaps, yellow fever, and also in diabetes mellitus.

It has long been an accepted proposition that urea is the result of the burning up of the tissues of the body. This is only partially true. One of the symptoms of diabetes mellitus is a large increase in the amount of urea. The temperature, however, is not feverish, and the abnormal quantity of urea is due to the fact that the over-active glycogenic cells are converting the nitrogenized principles of the blood into *glycogen* and *urea*.

Why, in certain cases, the surplus amount of glycogen should be converted into alcohol and carbonic acid, and in others be eliminated as glycogen, has as yet been unexplained.

The glycogenic ferment is presumably formed in the ductless glands of the liver, and that it is the active principle that converts sugars in the blood coming from the portal vein into its allotropic modification of glycogen is generally accepted as a physiological fact.

Diabetes is stated to be a nervous disease, and when the disturbance causing it is central, it is more than probable that the lesion to the great pneumogastric centre will disturb other functions than that of the liver.

Fever, on the other hand, if due to nervous disturbance at all, directs its effects in the main toward increasing the rapidity of the circulation of the blood, and the rise in temperature is generally accompanied by an acceleration of the movement of the heart and lungs. In all fevers, splenic disturbances are more or less marked. Now it is a fact that the chemical decomposition of sugar into alcohol and carbonic acid is performed by the aid of a micro-organism or ferment; hence such a ferment must exist in the blood. Therefore, supposing the quantity of the calorigenic ferment, if I may be allowed the term, to be present in the blood in normal quantity, it follows that the increase of glycogen dependent upon over-activity of the splenic circulation will be accompanied by a corresponding increase of calorigenic ferment passing through the liver, it will decompose the glycogen into alcohol and carbonic acid, a larger amount of heat will consequently be evolved, and fever will result.

It must be borne in mind, however, that cases may exist where there is an abnormally small amount of calorigenic germs in the blood, coexistent with an increased splenic circulation, and that the consequence in that case would also be glycosuria.

To recapitulate, therefore, it appears that diabetes mellitus can be caused by two conditions:

I. Over-activity of the glycogenic cells of the liver.

II. Increased quantity of blood passing through the splenic circulation, and in which the quantity of calorigenic germs is abnormally small.

Fever is also dependent upon two conditions :

I. An abnormal amount of calorigenic germs in the blood.

II. An increase in the quantity of blood passing through the spleen into the liver and containing a normal amount of calorigenic germs.

The argument has been advanced that the spleen cannot play an important part in the phenomenon of life, as its removal has not materially interfered with its prolongation. That, however, it is the great equalizer, a regulator of the correlations of the functions of the internal organs, I am firmly convinced. It holds the balance of power, so to speak, and the disturbance of its integrity is always attended finally by more or less grave complications. It is more than probable that a portion of the calorigenic germs are generated in the spleen while it is performing its function of altering the proportion between the different amounts of red corpuscles and leucocytes in the blood. That it is not the sole organ thus employed is patent from the fact that animal heat is still generated after its extirpation. At the same time, it must be borne in mind that important compensatory changes take place in the marrow of bone after its removal, and that Mother Nature, like the hydra of Lerna, has more heads than one, and that in the complex mechanism of life, so simple in some things, so indescribably mysterious in others, one of the great principles, without which human existence would be narrowed down to even a shorter compass than it now enjoys, is that of compensatory function.

Clinical Department.

PERFORATION OF THE SEPTUM.

By S. MITCHELL, Jr., M.D.,

HORNELLSVILLE, N. Y.

Many cases of ulceration and perforation of the cartilaginous portion of the septum occur, that are entirely independent of any syphilitic disease, but induced by the patients themselves, as I had occasion to observe in a case recently under treatment, and the one that serves as a text in presenting this subject. I have noticed that perforation of the septum, in its cartilaginous portion, is most frequently found in thin-featured people, where the lateral cartilages that should present convex surfaces outward, thus giving free, open nares, are reversed by a collapse of these cartilages, thus bringing their convex surfaces toward the septum. The constant contact of surfaces thus induced creates a feeling of obstruction that the sufferer seeks to remove by frequently introducing the finger into the nostrils. The result is, the septum is injured by the sharp finger-nail, a crust forms at the seat of the injury, which is torn away by the sufferer as often as it reforms, thus giving great relief (to his mind), but inflicting upon the septum each time a deeper injury, that finally results in a perforation of this thin partition, with ulcerated edges, and becomes a source of pain and annoyance until the edges are healed. When once healed, there is really great relief from the feeling of obstruction. The case above referred to I saw at the very outset of his trouble, and warned him of the result toward which he was hastening. In addition to warning I tried to induce him to wear, immediately under the cartilages, small dilators, made of silver wire—an idea first suggested to me by Dr. R. Jefferies, Jr., of Brooklyn. These appliances were discarded by him after a short trial, and, despite my continued warnings, his finger-nail was still employed as the best means of relief, until a short time ago, when he presented himself at my office with a perforation of the cartilage of the septum as large as a ten-cent piece. The edges around the whole circle were ulcerated, and the seat of considerable pain that extended to all parts of the nose and forehead. I informed him that the practice of removing the crusts must be discontinued, and the edges constantly protected in order that healing might be favored. With this end in view I removed all the crusts, prepared a thin pledget of cotton, exactly fitting the opening in the septum, smeared it thoroughly with ung. hydrargyri nitratis dil., and placed it in the opening, with directions to allow it to remain for twenty-four hours. This was complied with, and when he presented himself at my office the next evening he informed me that the pain was greatly diminished, and, contrary to his expectations, he had breathed more freely through his nose than usual. Upon removing the cotton I found the ulceration already rapidly healing. It was dressed as before, directing him to allow it to remain the same length of time. This treatment was continued for about two weeks, when healing of the ulcerated edges was complete. After the first few dressings this part of the treatment was delegated to my patient's wife, who devised a very novel and ingenious improvement on my cotton pledgets by stitching to either side of these circular pieces of canton-flannel, the diameter of which exceeded that of the cotton by one-eighth of an inch, thus making a flange on both sides of the cotton. Between these flanges the ointment was placed, and when this novel dressing was in position the projections of the cloth rested on the septum in both nostrils, and the cotton, with the ointment, was in contact with the ulcerated edges only. No one knows better than a doctor does that "necessity is the mother of invention," yet they sometimes wait for patients, or their ministering friends, to give an illustration of the fact.

PHTHISIS IN HAYTI.

By R. PERCY CRANDALL, M.D.,

ASSISTANT SURGEON, UNITED STATES NAVY.

A curious idea exists among the natives of Hayti in regard to phthisis pulmonalis. They believe it to be both contagious and infectious, and fear it much more than yellow fever or small-pox.

A native who is believed to be affected with this disease is avoided and shunned by all who know him, and becomes an object of prayer for the priests and of pity for the people.

When a consumptive dies, the entire contents of the room in which he died are either destroyed or thrown into some place set aside by the government for that purpose. This sacrifice of property not only includes the furniture of a room, but also articles of value, such as jewelry, gold, and precious stones. This idea of destruction is carried to such an extent by some, that the paper is sometimes removed from the walls, and the floors torn up. Cases have even occurred where small houses, in which deaths from phthisis have taken place, were burned down to the ground to prevent the spread of disease.

While riding one day near the suburbs of Cape Haytien, the commercial capital of Northern Hayti, I came across a sort of marsh or lake of mud known as the "*Cimetière des chevaux*." Scattered over its surface and half sunk in its muddy depths, were innumerable household articles, furniture of all kinds, sewing machines, pianos, bookcases, books, etc. Here and there also appeared the whitened skeletons of animals.

My curiosity being excited, I asked of a native, standing near, the reason for this apparent waste of property. He informed me that the *Cimetière des chevaux* was a repository for the dead bodies of animals, and for everything that was found in the room of one who had died from *la poitrine* (consumption). When asked if anything was ever removed from the cemetery, he answered that nothing would induce a Haytien to even touch anything that had been placed there.

I found this to be strictly true, as on several occasions I offered natives sums of money to bring me articles from the cemetery, and was always refused with looks of horror and repugnance.

On careful investigation, I found that phthisis was regarded as contagious by all classes throughout Hayti. En-

deavoring to trace this idea back to its origin, I found that it existed among the early African tribes who inhabited Hayti under the French rule, and that it was probably brought over with them when they were brought from Africa. This conclusion is rendered more probable by the fact that the majority of the West India negroes of African origin entertain the belief that phthisis is contagious.

I examined many cases where phthisis was supposed to exist, and found in every case well-marked and characteristic symptoms, the most common pathological condition being small cavities in the upper lobe of the left lung. Hemorrhages are frequent and night-sweats rare. The disease is much more frequent among women than men, and prevails chiefly among the lower classes.

In regard to etiology, heredity, sedentary habits, high temperatures, bad ventilation, and the faulty construction of the houses, with their damp earthen floors, may be considered as the chief causes. The average Haytien affected with phthisis will never admit that he has the disease, and to convince such an one that he is a consumptive is simply to shorten his life through fear.

Here, then, is an additional point for those who hold that phthisis is infectious.

ARTIFICIAL ANÆSTHESIA DURING SLEEP.

By J. W. CARHART, M.D.,
LAMPASAS, TEX.

On May 6, 1889, at about 5 P.M., I was summoned to attend a child about three and a half years of age, who had fallen, a short time previous, and fractured the right thigh at about the middle third.

The family were living in a tent, in a sheep camp, about five miles from town. It was raining at the time, the road was obscure, and the tent in an out-of-the-way place, and it was accordingly somewhat late when I reached the bedside of my little patient. I found him asleep. He had suffered, cried, and worried until exhausted with fatigue, and sleep, "nature's sweet restorer," had come to his relief. I said to my wife, who had accompanied me: "We will now make the attempt to chloroform the little fellow without awakening him. Experiments lately reported in our journals, as having been made in hospitals, would go to show that it cannot be done."

I was desirous, if possible, of negativing the hospital experiments, but more especially of treating my little patient without any more suffering and excitement. Accordingly, I commenced with the paper cone enclosing napkin, at considerable distance from his face, perfect quiet prevailing in the tent. I made very slow and gradual approaches until the cone covered the face, when the breathing soon indicated that anæsthesia was accomplished. Before touching the broken limb, I satisfied myself that he was profoundly under the anæsthetic. I then applied the silicate of soda splint, or fixed bandage, according to the method I reported, in my paper on the subject of "Silicate of Soda Splint or Fixed Bandage," to the twentieth session of the Texas State Medical Association, which report is published in the "Transactions" for 1888, p. 97.

He did not awaken until after the anæsthetic was withdrawn. There was no excitement, no struggle, and not the slightest indication of the transition from natural sleep to artificial anæsthesia, except the respiration.

I am satisfied that artificial anæsthesia can be produced during sleep, in suitable cases; in other cases failure would doubtless result. The reasons for such success or failure are admirably stated by Dr. B. F. Hart, in THE MEDICAL RECORD for November 9, 1889, p. 526, under the caption "Both Right and Both Wrong."

The Supreme Court of New Hampshire has decided that the State law requiring a license for the practice of medicine, surgery, and dentistry is unconstitutional.

Progress of Medical Science.

Observations on Tricuspid Stenosis.—From certain facts collected by Dr. Leudet, it would appear that the comparatively rare condition of stenosis of the tricuspid orifice may be either congenital or acquired. The former arises either in fatal endocarditis, or from a malformation producing an excessive amount of muscular tissue at the auriculo-ventricular junction. In consequence of the stenosis, there may also be patency of the foramen ovale and incomplete formation of the ventricular septum. Sometimes it is associated with pulmonary stenosis or lesions on the left side. Cyanosis is the most frequent symptom; and a systolic bruit, rarely a diastolic, may be produced; while the enlargement of the right auricle may occasionally be detected by percussion dulness crossing the sternum. Dr. Leudet has collected details of 114 cases of acquired tricuspid stenosis, 86 females and 22 males (in 6 the sex not stated); and in 57 no antecedent disease, such as rheumatism, chorea, typhoid fever, or scarlatina, was noted. The degree of stenosis may be considerable, and it may be produced by 1, cohesion of the valves; 2, true stenosis of the orifice; 3, obstruction by vegetations, etc. The first is the most frequent. It corresponds to a chronic, slow endocarditis, generalized rather than deep, and tending to cause the damaged valves to unite at their margins. In only 11 cases out of the 114 was the tricuspid stenosis solitary; usually there is concomitant mitral stenosis, which is always more marked than the tricuspid. Presystolic thrill and bruit at the xiphoid and above may be present, but do not appear to be common.—*L'Union médicale.*

Some Cases of Intestinal Obstruction.—Dr. Gelpke reports four cases of intestinal obstruction, of which two had been operated on, one with success, and two had been successfully treated with metallic mercury. From these cases he concludes that quicksilver is a valuable remedy in cases of obstruction, and that the metal seems to be quite innocuous to the system if not too long retained. It had been so retained in one of the two cases, in which four teaspoonfuls of quicksilver had been given, and the fæces and urine of the patient contained the drug for twelve weeks; there were other distinct symptoms of mercurial poisoning, such as great emaciation, excitement, loss of hair, and some stomatitis. The other patient, on the contrary, showed no signs of mercurialism whatever. He considers that in hernia it is generally advisable to commence the abdominal section from the orifice of the sac. Finally, considering the uncertain and not very successful results of laparotomy, he would not operate before other means, such as quicksilver, have been tried for from four to six days. Dr. Reitz has reported the case of a laborer suffering from obstruction of the bowels, who, after three days' fruitless administration of purgatives, was brought to the hospital. Fecal vomiting was present, and a tumor could be felt on the left side of the umbilicus. Enemata of water by the long tube, though as much as six pounds of water were injected, were unsuccessful, but the vomiting and sickness improved under repeated washing out of the stomach. The next day the patient was considerably worse, and fecal vomiting returned, with cold perspiration, restlessness, meteorismus, a pulse of 120, and a temperature of 100° F. After the enema with the long tube had been again used, and the stomach repeatedly washed out, without any improvement, seven drachms of bicarbonate of soda in five ounces of water were injected into the rectum, followed by three drachms of tartaric acid in the same amount of water, and the anus closed. The patient, who was on his knees and elbows, complained at once of severe abdominal pains, and in five minutes the injection came away with exceedingly offensive flatus. Shortly afterward the patient felt considerably better. In three hours the enema was repeated with half the previous doses, and was shortly followed by a large loose motion, and by a second later on. The patient completely recovered.—*The Lancet.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, January 11, 1890.

MURDER BY CHLOROFORM.

THE recent alleged case of the murder of one woman by chloroform, while asleep, and the narrow escape therefrom of her female companion in the same room, has brought up for discussion the possibility of such an occurrence, and the ventilation of many theories of the supposed means to such an end. Two women are said to have been sleeping in one bed, burglars enter the room, chloroform both the sleepers, and decamp. One of these is found dead in bed, with a portion of the coverlid, said to smell of chloroform, over her face; the other lying in a helpless condition on the floor, and apparently too dazed to give any consistent and intelligible account of her condition. The husband of the dead woman, a dentist, was away from home at the time. The results of the autopsy upon the woman are said to be so unsatisfactory as to cause the coroner to inquire into other probable causes of death than the one suggested.

Without attempting to anticipate a verdict in this case, the questions of possibility and probability of murder by chloroform, and while asleep, offer some interesting points from purely unbiassed and strictly scientific stand-points.

Very soon after the discovery of chloroform as an anæsthetic, and the wide publication of its wonderful powers, grave fears were entertained of its more or less extensive use by burglars and other criminals. Notwithstanding, however, this feeling of alarm, which at the time was shared by many legislators and other leading men in Great Britain, agitated as it was by all sorts of exaggerated propositions, there has been little, if any, experience in the jurisprudence of such cases up to the present time. Scarcely a dozen of these have come before the courts, and these were either for burglary or felonious assault, but never yet, as far as we can ascertain, for murder. In no instance has it been proven that chloroform, when alleged to have been used at all for either of these crimes was to any purpose.

Dr. Snow, the eminent authority on anæsthesia, boldly expressed his belief in that direction many years ago, and more recently the exhaustive paper on the subject by the late Stephen Rogers, of this city, placed the possibility of the use of chloroform for burglarious purposes at least almost beyond the pale of argument. After examining with critical care the alleged cases in which such attempts were made, he very properly concludes that there is great liability to err on the part of courts, unless upon detailed inquiry into the circumstances and manner of giving the chloroform they be found consistent with the thoroughly well-known facts and phenomena uniformly attending the administration and action of the agent.

The same conclusions would apply with especial force to the supposed cases of murder, especially when the crime is alleged to have been committed while the victim was asleep. Concerning the latter element of this proposition, enough has already been written to place the settlement on a very well-recognized basis. The numerous observations regarding the possibility of inducing anæsthesia during sleep have quite conclusively shown that it is only with the greatest care on the part of an experienced practitioner that such can be accomplished at all, and then only in exceptionally favorable cases with particularly fortunate surroundings. Again, while this condition of things can be sometimes produced with infants and young children, as shown in many cases, one of which is reported in this issue, it is virtually impossible in the cases of adults.

The interesting observations of Dr. J. H. Girdner, of this city, on this point, prove how easy it is to awaken suddenly and with alarm the soundest sleeper at the very commencement of the inhalation, even when the napkin containing the chloroform is held a considerable distance from the face. Aside from the favorable surroundings necessary for success in these cases the element of time in the effective administration of the drug is no inconsiderable one to take into account, adding as it does a proportionate risk of detection in the act.

Considering also the comparative rarity of induced anæsthesia without struggle, noise, or vomiting by the victim, the chances of being discovered are increased in proportion. Such incidents also would be likely to alarm the criminal even more than the victim, in fear that, if not detection, actual murder might be the result.

To return to the case which forms the text of these comments, a few pertinent inquiries suggest themselves as bearing upon the theory of chloroform-murder by burglars. How could the deed be accomplished as explained by the fact that one of the victims was found dead in bed and the other lying on the floor? Which one was chloroformed first? Is it possible to conceive that, lying side by side, one or the other would not be awakened to give an alarm, even if the drug was administered to both at once? Or, was one promptly strangled, and the other simply overcome in her struggles subsequently? With one murder staring them in the face what would have been the incentive of the criminals to commit another against such desperate chances as a determined and desperate resistance by the remaining victim?

The autopsical revelations may make many points clearer than at present. The main one to prove is, whether or not chloroform was the lethal agent at all; but more difficult than all will it be to explain how the deed was actually done, consistent with the well-recognized difficulties of chloroform administration under such circumstances. The responsibility of settling these questions must, however, rest with the jury which shall try the case.

COLORADO AND CONSUMPTION.

IT is important that we should have, from time to time, reports from the practising physicians of health-resorts in regard to the advantages to be gained by sending patients

to them, for the resident practitioner alone knows to what extent the patients conform their habits to the needs of the locality, and what are the special drawbacks to which foreign residents are subject. He can decide better, also, in what forms or stages of the disease residence in his district is beneficial. In the Trans-Colorado State Medical Society, 1889, Dr. Fisk, of Denver, gives what seems to be a very impartial review of the influence of the climate of Colorado on the health of consumptives sent there from other States; basing his statement on an analysis of a hundred recorded cases in which he has been able to keep the patient long enough under observation to tell what the effects of his sojourn have been.

Fifty per cent. of all cases received so much benefit that they were able to pursue their occupations without serious inconvenience.

Seventeen per cent. of all cases were somewhat improved, but had always to use certain precautions, and to limit their exertions. Many of these returned to their homes.

Seven per cent. of all cases became worse, largely because of their own imprudence.

Twenty-six per cent. of all cases died.

Thus two out of three received benefit from their residence in Colorado. Nearly all of those who were entered as "worse," and nine out of the twenty-six who died were doing well until some imprudence caused a permanent relapse.

His figures show that men are more apt than women to secure an arrest of pulmonary disease by going to Colorado. Perhaps one of the most potent causes of this difference is the greater ability of men to endure separation from home and change of surroundings.

The chances for improvement are better after thirty years of age. The general law for all countries holds here too; that in fatal cases the course of the disease is shorter in women than in men.

In only twenty-five per cent. of the hemorrhagic cases did hemorrhage return in Colorado, and in many of these instances it was brought on by immoderate exercise. In only two non-hemorrhagic cases did hemorrhage occur in Colorado, and then it was due to unusual exertion. This proves that the climate is suitable for hemorrhagic cases.

The prognosis depends very greatly on the ability of the patient to sleep and to eat and digest food. Thus, a patient with good appetite and good digestive powers, with regular action of the bowels, is likely to improve, while a patient with equal hereditary predisposition and equally advanced disease of the same form, but with poor appetite, bad digestion, and constipated or irregular bowels, is likely to receive little or no benefit.

As might be expected, rapid pulse and high temperature are indications that the course of the disease will be unfavorable.

Realizing the difficulty which even skilled diagnosticians find at times in determining the exact stage in which the disease presents itself in certain patients, and the uncertainty of their prognosis in such cases, Dr. Fisk has adopted a classification of his own.

In the first class, where there is "slight trouble," a small part of the apex of one or of both lungs, or of the base of one lung, being involved, there is a good chance for improvement in Colorado.

When the patient presents "marked trouble," the whole of one lobe being affected, or râles being heard in two separate lobes without softening, he may be sent with the hope of getting some improvement.

If dulness is very distinct over one or more lobes, and if there is at the same time tubular breathing and unmistakable bronchophony, with râles of various sorts, even though he cannot positively diagnosticate cavities (as, indeed, he is very slow to do), he considers that there is "considerable trouble," and thinks that the patient had better be kept in his own home, especially if there is impaired appetite and digestion, with hectic and rapid pulse.

Of the one hundred cases five exhibited undoubted tubercular laryngitis. Two of these recovered, one made some improvement, one became worse, and one died. A patient with an empyemic cavity on the left side submitted to resection of the ribs, and recovered so far as to attend to his business without difficulty. Two others, in whom the fibroid condition on the left side caused the heart to be drawn up and to the left of the nipple, were very much improved, and still improving. Another was taken with acute endocarditis about six months after his arrival, but came through it safely and is doing well. Five had had syphilis. Two of these were much improved, one somewhat improved, one became worse, and one died. Several weathered rheumatism or typhoid fever without additional damage to their lungs.

THE POSSIBILITIES OF LAPAROTOMY.

It will certainly be an encouragement to laparotomists to learn what can be done with the intestines without adding danger to the operation by sudden shock. A report comes to us from California of the following remarkable instance of vitality. A maniac performed hara-kiri in the presence of his companion, who was wakened from a sleep by the noise. Standing in the middle of the floor was the suicide, with protruding intestines. Policemen were summoned, and thus the account runs: "The man was still in the middle of the floor, standing in a lake of blood, tearing out his vitals, and cutting them off in sections and throwing them in a heap on the floor.

"The officers grappled with the maniac, but, notwithstanding his frightful loss of blood, he still possessed the strength of half a dozen men.

"After a desperate struggle, however, they succeeded in overpowering him. He was then handcuffed and taken to the Receiving Hospital. A great pile of intestines were left stringing about the room. When he was brought into the hospital three or four feet of his bloody vitals dragged upon the floor."

Nothing further in the shape of an operation could be done after getting the patient to the hospital, save trimming off a few of the remaining intestines to make him more comfortable. But he died two hours afterward.

THE ASH-CART NUISANCE.

One of the greatest nuisances of this city, and one that calls for a speedy abatement on the score of its menace to the health of our citizens, is the mode in which the ashes and garbage are removed. At one time it was the

practice to empty the dusty and foul-smelling barrels in the night-time, when most respectable people, except policemen and doctors, are safe at home, and this was perhaps the best that could be done. Lately, however, we have noticed that the rounds of the ashman are made once more in the daytime, and the lungs of passers-by are filled with the possibly disease-laden dust, and their stomachs are turned almost inside out (to speak after the mode of the ordinary citizen, and not in scientific terms) by the villanous odors of decaying animal and vegetable refuse. Cannot this nuisance be abated, and one of the miseries of life in a great city be thereby prevented?

News of the Week.

The Treatment of Influenza. — M. Henri Huchars, writing in the *Revue générale de Clinique et de Thérapeutique* of December 12, 1889, offers some suggestions concerning the treatment of influenza which may be of interest at this time. "In all epidemics of the disease," he says, "the most marked clinical feature is the adynamic character of the symptoms, and it is against this that treatment should be chiefly directed. For this reason preparations of cinchona, alcoholic beverages, and the like should be prescribed early; and in grave cases, when the prostration is profound, injections of ether or of caffeine may be needed. Quinine is usually indicated by the remittent character of the fever, and, for the control of this, should be given in one dose of from eight to fifteen grains in the forenoon. If the fever persists in spite of this, it may be well to give fifteen grains of antipyrine in the evening. But even when the fever is not high the use of quinine in tonic doses is advisable. In the rheumatoid or neuralgic forms, characterized by severe pains in the joints, muscles, and other parts of the body, we may resort to antipyrine in doses of fifteen grains two or three times a day. Instead of this drug we may use phenacetine or salol in eight-grain doses. When the disease assumes the broncho-pulmonary form the adynamia is commonly very pronounced, and the necessity for stimulants becomes even more pressing. The nourishment should consist chiefly of milk, which acts as a diuretic, and favors the elimination of the waste-products. Blisters are inadmissible in the pneumonia following influenza, which is pre-eminently a local manifestation of a general disease, for they do not benefit the local process, and only aggravate the general condition. Occasionally the dyspnœa, even when the pulmonary affection is apparently limited in extent, becomes extreme. In this case much benefit is often derived from the use of strychnine. Sometimes, especially in the renal form of the affection, the only thing that will relieve the dyspnœa is a venesection, though ordinarily this is the last thing to be thought of in a disease in which the adynamic tendency is so pronounced. In the gastro-intestinal form it is necessary to employ mild purgatives, such as castor-oil or calomel, and to obtain intestinal antisepsis by means of salicylate of bismuth, or of magnesia, naphthol, etc. If an emetic is at any time indicated, tartar emetic should never be used, but ipecac given in preference."

The Epidemic Influenza of 1847 was accompanied, according to Dr. Horace Dobell, with severe catarrhal symptoms of the upper respiratory passages. While this is not the case with the present epidemic, yet the directions for treatment given by Dr. Dobell in such cases are sensible, and will apply occasionally now. He enjoins the following measures: 1. It is best to go to bed at once, and take hot gruel, hot tea, and beef-tea for diet during the more acute state, resuming ordinary solid meals as soon as practicable. 2. The bowels should be kept well open (but not much purged) by any aperient known to act most kindly with the patient. 3. The use of the following inhalation should be begun immediately: ℞. Creasoti, 3 j.; olei caryoph., 3 j.; olei eucalypt. glob., ℥ j.; tr. camph. co. ad ℥ ij. Shake the bottle, and put one teaspoonful into a four-pound jam jar, nearly fill it with boiling water, wait two minutes to let the hottest steam pass off, and then hold the face well over the jar, and throw a large light handkerchief over the head and the jar; shut the eyes, and let the forehead and face be thoroughly exposed to the steam, which should be drawn up the nostrils and blown out at the mouth. Continue this as long as steam lasts (about fifteen minutes), and repeat every two hours. 4. In the interim, gargle occasionally with hot water, and let all secretions from the nose and throat be ejected. 5. Soon after the first inhalation, begin the following restorative febrifuge: ℞. Sp. camphoræ, 3 j.; sp. ætheris nitr., ℥ j.; tr. quin. ammon. ad ℥ ij. Ft. Guttæ. One teaspoonful stirred in a claret glass of water every three hours. 6. If the temperature rises above 101° F., take gr. v. of antifebrin in two tablespoonfuls of beef-tea, and repeat every hour till the temperature falls to 100°, continuing the inhalations and drops as before. 7. If pain or oppression at the chest sets in, apply hot poultices.

The Grippe or the Dengue.—At a discussion before the Académie de Médecine of Paris on the prevailing epidemic, the question was raised whether it was the epidemic influenza *la grippe*, or the dengue. The general opinion was that it was not the dengue, but that this latter disease has a striking similarity in some respects to the *grippe*.

A Brief Account of the Present European Epidemic. —The following brief history of the epidemic of influenza, so called, shows how closely the European disease resembles that which is prevailing in this country. It may briefly be described, says the Vienna correspondent of the *Medical Press*, to have taken its origin in or about Wassili-Ostrow and Kolomna, southwest of St. Petersburg, about the last week of October or the first of November, and rapidly spread north to the capital, filling the hospitals, barracks, etc., and paralyzing commerce. At this season of the year the atmosphere was unusually warm, moist, cloudy, with west winds. Within three weeks after its appearance the half of the population of St. Petersburg were rendered prostrate from its influence. Its contagion or infection is not at all satisfactorily proved. One in a family may be very ill, while all the others enjoy immunity. Again, whole families are laid down in rapid succession, and in others the half of the family may be exempted. It has no decided predilection for age or sex, although the very old are believed to escape its ravages. The incubation period is definitely fixed at two days, while the prodromal symptoms are but a few hours, whose description is given as prostration, headache, shivering, etc., as given in other infectious dis-

eases. The varieties of the fever itself are divided into three groups: 1. Those with pure nervous symptoms, as headache, pains in the limbs, neuralgic pains in trunk, as in pleuritis. The respiration and pulmonary mucous membrane normal, as well as alimentary canal. This form is the most common, and has on many occasions been diagnosed as typhoid. 2. The catarrhal form: Bronchial catarrh, sneezing, continuing several days after the fever subsides. 3. Gastric: Catarrh of the alimentary tract with persistent vomiting. Besides these varieties, a great number of other symptoms are given, common to all, as giddiness, hyperæsthesia, etc., which soon disappear. The temperature rises rapidly to 40° or 40.5° C. (104° to 105° F.); continues at this about two days and rapidly falls. The duration of the fever is usually three days; seldom five or six. Very little alteration of the spleen is observed. Convalescence is very variable, and seems to depend more on the intensity of the attack. Many feel themselves fit for work the day after the fever has subsided, while others suffer from nervous or catarrhal symptoms for days after. Relapse is not uncommon. Seven days after the patient has recovered, and is seemingly quite well, shivering again commences, and the whole symptoms are repeated.

The Man who Started the Grip.— Agrippa.

Pneumonia Prevails in this City to a greater extent this season than for many years past. In the meantime the epidemic of influenza is declining.

"Grip" patients have a Disagreeable Odor, so says Dr. W. Washburn, of this city, who has noticed it in several of his cases.

Chinese Physicians cannot Practice in New York without a License, so says the coroner's jury in the case of a Dr. Nam, who attended a Chinaman who died recently. The "Dr." has left his diploma in China!

Big Fees.—The doctors who attended the late King of Portugal during the last few weeks of his illness presented bills for their services amounting to nearly $100,000. One of them demanded $14,000 for ten visits, another demanded $17,000 for fifteen, while a third thought that $30,000 was not too much to ask for his attendance at eighteen consultations. Eventually the new King succeeded in effecting a settlement of their claims by means of a lump sum of $60,000. Of course this was polite robbery. In too many cases such estates are robbed. It seems to make no difference whether the patient is killed or cured, the bill for services is too often made out according to the size of the sick man's estate.

The New York Pathological Society.—The following officers were elected at the annual meeting of this Society held January 8, 1890: *President*—Dr. J. West Roosevelt; *Vice-President*—Dr. H. P. Loomis; *Treasurer*—Dr. J. H. Hinton; *Secretary*—Dr. T. L. Stedman; *Editor of the Transactions*—Dr. G. C. Freeborn; *Committee on Admissions and Ethics*—Drs. W. P. Northrup, H. P. Loomis, R. H. Sayre, J. S. Ely, and R. G. Freeman; *Committee on Publication*—Drs. T. M. Prudden and W. B. James.

Trichinosis.—Seven cases of trichinosis occurred in one family in Austin, Minn., last week, one, a boy ten years of age, died. The pork was not properly cooked, as usual.

City Lodging-houses. — Dr. Henry C. Crampton, of this city, read a paper before the Section on Public Hygiene of the Academy of Medicine advocating the enforcement of the law for city lodging-houses. We shall give his views on the subject in a coming issue.

A Healthy Society.—It is worthy of note, says the *Boston Medical and Surgical Journal*, that the average age of the decedent members of the Massachusetts Medical Society, so far as recorded, reached the high figure of *sixty-eight and one-half* years, a fact which speaks well for the salubrity of the conditions attending medical practice in the Bay State.

A Kilometric Title.—The Spanish Gynecological Society held its first meeting this winter on December 4th, under the presidency of Dr. Francisco Alonso Rubio. The introductory address was delivered by Dr. Enrique Oliván; the gist of it is sufficiently indicated by what the Spanish reporter calls its "kilometric" title: "Some reflections tending to show that the confidence at present inspired by anæsthetics, and the use of modern antiseptic methods, neither justifies nor excuses the practice, far too frequent nowadays, of intra-abdominal operations, and more especially of those termed exploratory laparotomies."

Politics and Pension Boards.—The *Kansas City Medical Index* states that the Pension Board of that city does not contain any of the regular and representative medical men, but has been selected from an "irresponsible horde" of "uneducated quacks" whose merit lies, it is presumed, in their political influence. The Kansas City physicians should take some interest in promoting civil service reform, if affairs are as their local journal indicates.

The American Physiological Society held its annual meeting in New York, December 29th. The Society elected the following council: H. P. Bowditch, J. G. Curtis, H. N. Martin, S. Weir Mitchell, and H. H. Donaldson.

A Fair Division of Service.—The Board of Charities and Correction of Philadelphia have decided to distribute the medical service of the Blockley Hospital equally among the medical colleges. But what about the good men and true who may not be professors? Naturally, they must be outside and look on.

The Late Professor Volkmann.—It is said that Schede, of Hamburg, will succeed the late Dr. Volkmann as Professor of Surgery at Halle.

Money for Charities.—The Brooklyn Board of Estimates has finished its labors for 1889 by apportioning among the various local charitable organizations the sum of $100,000, set apart for them from the money collected for excise fees. Sixty-five societies benefited by the fund, but, as usual, the Catholic organizations took more than half the entire sum distributed. Ten of them received $55,614.47. The fortunate ones were St. Catherine's, St. Mary's, St. Peter's, and St. Mary's Female Hospitals, the Holy Innocents' Union, the Home for the Aged in Eighth Avenue, and the Home for the Aged in Bushwick Avenue, St. Paul's Industrial School, the Roman Catholic Orphan Asylum, and the Convent of the Sisters of Mercy.

To Keep out Lepers.—The following order has been issued by Secretary Windom: Until further orders, no vessel shall be admitted to entry by any officer of the Customs until the master, owner, or authorized agent shall produce a certificate from the Health Officer or Quarantine Officer of the port of entry or nearest United States Quarantine Officer, that no person affected with leprosy was on board the vessel when admitted to free pratique, or, in case a leper was on board such vessel, that he or she, with their baggage, had been removed and detained at Quarantine. Second—Medical officers in command of United States Quarantines are hereby instructed to detain any person affected with leprosy found on board any vessel, but such officer will permit the departure on outgoing vessels of persons detained at Quarantine in pursuance of this regulation, provided such vessel shall be bound to the foreign country from which the said leper shall have last sailed.

The New City Hospital of Baltimore, Md., was formally taken charge of last week by the faculty of the College of Physicians of that city, on which occasion a reception was given to the medical profession at large.

Deaths from Hydrophobia.—The deaths from hydrophobia in London were fewer last year than in any year since 1868. As compared with 60 deaths in 1885, 26 were recorded in 1886, 29 in 1887, and only 14 in 1888, so that muzzling appears to have had good results.

The Middleton Goldsmith Lecture will be delivered by Dr. William Pepper, LL.D., Provost of the University of Pennsylvania, on the evening of January 15th, in the hall of the Academy of Medicine, at 8 o'clock. Subject, "Hepatic Fever."

The Late Dr. Lewis Hall Sayre.—At the annual meeting of the Alumni Association of the Bellevue Hospital Medical College, January 4, 1890, on the announcement of the sudden death of our much-esteemed President, Lewis Hall Sayre, M.D., the following resolutions were adopted: 1. That the Association receives this intelligence with deep sorrow, and mourns the loss of a member so efficient, so kindly, and so generous withal. 2. That we extend to the family our sincere sympathy in this their greatest hour of affliction. 3. That we attend in a body the funeral services of our late President. 4. That copies of these resolutions be sent to his family and to the prominent medical journals of this city for insertion. V. P. Gibney, M.D.; Henry Goldthwaite, M.D.; David Webster, M.D.

Non-tubercular Hæmoptysis.—Dr. T. J. Whitney, of Frewsburg, N. Y., writes: "I was much interested in your article from Sir Andrew Clark, on 'Non-tubercular and Non-cardiac Hæmoptysis.' The conclusions were sound. And allow me to add to conclusion 5: all of which relieve portal engorgement, a possible source, and, I think a frequent one, in all venous hæmoptysis. A half a grain to a grain of calomel, followed in twelve hours by a saline, giving perfect relief.

The American Medical Association of Vienna is the name of an organization founded with the object of looking after the interests of British and American medical students who go to Vienna to study. The Rev. Francis Gordon is secretary.

Equine Laryngoscopy.—Professor Polansky and Dr Schindelka, of the Vienna Veterinary School, have constructed a laryngoscope for horses, by means of which active treatment in cases of glanders can be carried out.

Castor-oil Sold by Druggists.—A French tribunal has recently decided that castor-oil, not being a pharmaceutical product, may be sold by grocers. The decision suggests the query whether the retail stores of this city, which deal in a great many pharmaceutical products, such as quinine, coca-wine, iron, etc., are doing this legitimately.

The Death of Dr. David Prince took place at his home in Jacksonville, Ill., on December 19, 1889. Dr. Prince was born in Connecticut, in 1816. He graduated in medicine at Cincinnati, and practised and lectured for a time in St. Louis. Dr. Prince was well known for his wide learning and his surgical skill. He was the first Illinois surgeon to use ether. For some years he had been at the head of a successful surgical sanitarium.

Salt for Headaches.—An English doctor reports over thirty cases of headache and facial neuralgia cured by snuffing powdered salt up the nose.

A New Antipyretic, called phenyl-urethan, is announced by Giacomini, of Turin. Its dose is about half that of antipyrin, viz., seven or eight grains.

Cleveland has a New City Hospital containing one hundred and fifty beds. The patients are all under the care of one physician, who receives a salary of $1,200. There is no visiting staff, and all the work, surgical as well as medical, falls upon the single medical officer.

Koch and the German Sanitary Department.—The great centre of the official sanitary inspection system of the German empire is "Das Reichs-Gesundheitsamt," and "Das Hygienische Institut," both presided over by the illustrious Koch. There is really no more unpretending physician or teacher in the whole Fatherland than Professor Koch, although his name is a household word all over the world, and the government has showered money, titles, and honors on him. A week or two ago I saw him enter a third-class car on the elevated railroad, while possibly none of his students would regard it consistent with the dignity of a "Musensohn" to travel in any but the second-class. Koch's charming simplicity is a refreshing contrast to the usually exhibited presumption of German celebrities, and reminds one of a distinguished American anatomist, who, inquiring once for the cause of the students' applause as he entered the lecture-room, learned that a tribute was paid to his new suit.—*Therapeutic Gazette.*

Zinc in American Dried Apples.—The Berlin president of police issued a few days ago an official warning against the use of American evaporated apples, which, it is stated, contain salts of zinc. This warning having been published in all German papers, it cannot fail to react on the American wholesale dealers of this article, who have thus far supplied the German market.—*Therapeutic Gazette.*

Remarkable Fecundity.—A lady in Corry, Pa., is reported to have given birth to three children within thirteen days' time. This would make on the average one every four days. One infant died, but the parents are reported in good health.

Gottingen, the famous German university, recently celebrated the inauguration of a new surgical clinic, which is probably the finest institution of the kind in the German Empire.—*Therapeutic Gazette.*

The New York Death-rate, last week, was 39.31, the absolute number of deaths being 1,202.

The Salem (Mass.) Hospital Trouble is caused by disagreements between the medical staff and management, occasioned by the overt attempt of the latter to insult and humiliate the former. The natural consequence has been a resignation of the medical staff. Thus history repeats itself.

American Association of Anatomists.—At the meeting of this society, held last week in Philadelphia, Dr. Leidy presiding, papers were read by Professor Burt G. Wilder, of Ithaca, N. Y., on "The Transition from Stratified to Calomnar Epithelium;" by Professor Harrison Allen, of Philadelphia, on "The Value of the Studies of Variation;" also by Dr. Wilder on "The Heart as a Basis of Intrinsic Toponymy," and by Dr. J. L. Wortman, of Washington, D. C., on "The Superiority and Cheapness of Bichloride of Mercury as a Preservative of Anatomical Specimens as compared with that of Alcohol."

A Curious Trial of an Unlicensed Practitioner.—In a recent trial of an unregistered quack in St. John's, N. B., it appeared that a member of the medical society appealed to the said quack for medical advice, pretending to be a patient. The quack responded, and prosecution followed, with conviction. On an appeal of the case, the justice decided in favor of the defendant, on the ground that the plaintiff prostituted a high and honorable calling by tempting the victim to a violation of the law.

A Suit for $5,000 Damages has been brought against Dr. Herman Knapp, of this city, for alleged neglect of a patient in his hospital, resulting in death from pneumonia after an operation for cataract. The defence is that there was no neglect whatever, as every medical man will readily believe.

Proposed Down-town Hebrew Hospital.—A movement has been on foot for a month past to start a new Hebrew hospital, the object of the founders being the benefit of resident Hebrews of the poorer class, and especially those living in the lower wards of the city, and on the great East Side. In Mt. Sinai Hospital Hebrews are admitted after a certain period of residence in the United States, but it is understood that in the proposed hospital all Hebrews may be admitted who are not otherwise cared for by the Jewish Immigration Society.

Boston's High Death-rate.—The number of deaths in Boston last week reached the probably unequalled number of 327, of which forty per cent. are due to acute lung disease and are traceable in a great part to the prevailing epidemic "la grippe." The death-rate is 40.77, whereas in the corresponding week of 1889 the rate was only 21.67.

Dr. Charles McMillan, medical referee of the Pension Bureau, and well known in army circles, died in Washington, D. C., January 7th, of pneumonia. Dr. McMillan was appointed surgeon in the volunteer service from New York, August 3, 1861, and was mustered out, October 7, 1865.

Testing the Electrocution Apparatus.—During the past week Harold P. Brown's instrument for execution was tested in the presence of experts, a horse and calf being the subjects. The old horse was killed first. A quantity of cotton was fastened to his head and around his right hind leg. Then the wires were attached and the current turned on. The contact of the current with the horse's body was less than half a minute. He was killed instantly. The current registered about 1,000 volts. Dr. Macdonald said that this confirmed the experiment which he and Dr. Rockwell had had with a horse at Edison's laboratory last summer. The horse killed then did not struggle. In the case of the calf, Dr. Macdonald said that the current was of the same voltage as the one used on the horse. The contact on the calf was less than ten seconds. As soon as the calf fell over, Dr. Fell went to work on its body to see if animation had simply been suspended. He performed the operation of tracheotomy, opening the windpipe, and kept up an artificial respiration for half an hour, but there was no sign of returning life. The heart of the calf could not be made to beat again, and the members of the commission were in high glee, because Dr. Fell's apparatus has been used with success in five cases upon human patients.

Syms Operating Theatre.—Work has just been begun on the construction of the new building to be known as the William J. Syms Operating Theatre of Roosevelt Hospital, which the late Mr. Syms, a wealthy New York business man, who died last spring, willed $350,000 to construct and endow. The new building, as we have previously stated, will be of granite, and will occupy the present garden-plot on the Ninth Avenue front of the grounds of Roosevelt Hospital. It will have a frontage of ninety feet on Fifty-ninth Street, and a depth of seventy-five feet, and will cost between $150,000 and $175,000, leaving nearly $200,000 for maintenance. The theatre will be for the free instruction in surgery of students and practitioners. The theatre proper will occupy the centre of the building, will rise to a height of three stories, and will have amphitheatre tiers of seats capable of accommodating three hundred persons. Around the amphitheatre will be built a one-story structure with plate-glass skylights, to be used for the manufacture of surgical dressings, implements, etc.

St. Louis Medical Society.—Dr. J. K. Bauduy was elected president of the St. Louis Medical Society at its recent annual meeting, and Dr. F. D. Mooney, vice-president.

The Risk of Fire in Hospitals.—By the direction of the Commissioners of Charities and Correction, Battalion Chief Fisher and Captain Welsh, of the Fire Department, have been making an examination of Bellevue Hospital, with a view to suggesting means for the better protection of the hospital from the danger of fire.

How is this about the Medical Law in Alabama?—At the recent trial of a quack in Alabama, for violating the provisions of the medical statute, and his conviction, it was ascertained that there was no penalty affixed to the crime. The alleged reason for this is that the law was so tampered with during its passage through the Legislature that the penalty was omitted.

Hay in Street-cars.—Medical Inspector Taylor, of Philadelphia, very properly declaims against the use of swamp hay in street-cars, as follows: "I have investigated the complaint about the use of swamp hay in the cars of one of the passenger railway companies," said the doctor, "and find that, during wet weather, the hay becomes saturated with water and loaded with the expectorations from scores of tobacco-chewers, the sputa from tuberculous lungs, and street filth from passengers' shoes. The moist exhalations from this mass of filth are pernicious and prejudicial to public health. If this hay is dried and used again the dust that is given off from the movements of the passengers finds lodgement in many delicate mucous membranes." Perfectly right, doctor, we agree with you in declaring the practice a public nuisance.

The Standard of Vision in the War Department.—The Secretary of War has directed that the standard for vision prescribed for the army may be departed from for the enlistment of members of the hospital corps, to the extent that applicants may be accepted who are subject to refractory errors, such as myopia, hypermetropia, presbyopia, and astigmatism, provided these errors are not excessive, and are not accompanied by ocular disease.

Twenty-five Cent Fees.—Camden pays its doctors twenty-five cents for each case of contagious disease reported. In many places the law makes it so clearly the duty of physicians to report such cases that a fee is not given, but if this fee stimulates the reporting of contagious diseases, the money is well spent.—*Sanitary News.*

Habitual Arsenic Eating.—On this subject Dr. Norman Kerr contributes a paper to the journal of the Society for the Study of Inebriety. The observations he records are sufficiently startling. He has known persons so to habituate themselves to the poison as to be able to take ten to fifteen grains daily, and profess to feel better for it. Ladies, he states, swallow arsenic to improve their personal appearance, and also use it externally for the complexion. Gentlemen are also addicted to this practice, and both sexes take doses of arsenic as a fillip and general tonic. Cases of this kind have been reported in this country.

Obituary.

JAMES H. HUTCHINSON, M.D.,

PHILADELPHIA, PA.

Dr. James H. Hutchinson died suddenly, December 27th, of uræmia. On Wednesday night he retired in good health, and on Thursday morning arose to take his bath. Some considerable time later he was found unconscious. Drs. Ashhurst and Sinkler were summoned, but medical skill failed to revive him, and he died without having uttered a word from the time he was stricken.

Dr. Hutchinson's is one of the oldest families in Philadelphia on both sides. His widow was formerly Miss Ingersoll, daughter of the late Charles Ingersoll. His father, the late I. Pemberton Hutchinson, was widely known and held a number of important public positions. It was during his consulate at Lisbon, Portugal, in 1834, that James H. was born. At the age of about four years the deceased came to Philadelphia with his parents. In early life he was sent to a boarding-school in New Haven, Conn. Later he returned to Philadelphia and entered the University of Pennsylvania, from which he graduated in arts and medicine in 1858. He then served a term as resident physician of the Pennsylvania Hospital, after which he spent a year in Europe, visiting the hospitals in Paris and Vienna.

Upon his return to Philadelphia he took up the practice of his profession and became prominent in a number of professional, philanthropic, and educational institutions. He was vice-president and honorary librarian of the College of Physicians; was an influential manager and chairman of the Household Committee of the Pennsylvania Institution for the Instruction of the Blind; was a trustee of the University of Pennsylvania, and took a deep interest in its progress. He was a director of the Philadelphia Library, and was an attending physician at the Pennsylvania and Children's Hospitals. Dr. Hutchinson was widely known in both professional and social circles, and was also a vestryman of St. James's Protestant Episcopal Church. He leaves a widow and five children.

The College of Physicians of Philadelphia passed appropriate resolutions to his memory.

LEWIS HALL SAYRE, M.D.,

NEW YORK.

Lewis Hall Sayre, a son and assistant of the eminent surgeon, Lewis A. Sayre, died suddenly, some time during the night of January 2d, of heart failure. He had been somewhat run down with overwork, and was in addition a sufferer from the prevailing epidemic, la grippe, but was not known to be suffering from any other disorders, and did not refrain from his professional duties. On Thursday he went to New Jersey to attend a patient, and returned to his father's residence, No. 285 Fifth Avenue, which was also his own home, late at night, after the other members of the family had retired. As he did not appear at breakfast, and his room and bed not having been disturbed, it was supposed that he was detained overnight in New Jersey.

While the family were at breakfast the office-boy arrived, and upon opening the office-door was terrified to find Dr. Sayre sitting bolt upright in a chair, cold in death. He had returned in the night, and, after throwing off his overcoat, had seated himself in the office. Apparently he had been taken with a difficulty in breathing, for he had torn his shirt and collar open. An autopsy held by Dr. Delamater and Coroner Jenkins showed a disordered condition of the liver and kidneys—a fact for the first time made known to his father and brother, with whom he was engaged in practice.

Dr. Sayre was born in this city in 1851. He obtained his general education in the College of the City of New York, and his professional diploma from Bellevue Hospital Medical College. He was an assistant professor of orthopedic surgery in Bellevue Hospital Medical College, a member of the Academy of Medicine, and of several State and national medical societies.

Everyone will feel the deepest sympathy for the bereaved father, who has thus twice been suddenly robbed of a son.

GEORGE D. PARMLY, M.D.,

SPOKANE FALLS, WASH.

The news of the death of Dr. Parmly, on Monday last, was a surprise to men who remembered Dr. Parmly as one of the strongest athletes that ever entered a college. He was a Princeton man of '76, and was in his thirty-fourth year when he died. His name is well known to all old Princeton men who took an interest in intercollegiate sports in 1875 and 1876. Mr. Parmly was a heavy-weight athlete. His chest measured 45 inches, he was 6 feet 1 inch in height, and weighed 185 pounds. He was very successful in his medical studies, and gave promise of a brilliant career, until his health broke down.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON THEORY AND PRACTICE OF MEDICINE.

Stated Meeting, December 17, 1889.

R. C. M. Page, M.D., Chairman.

Heating Carbonic-Acid Water without the Escape of Gas.—Dr. J. West Roosevelt exhibited "Warker's Ingenious Apparatus for Heating Carbonic-Acid Water without the Escape of Gas." In this apparatus, in order to deliver the gas in the water, when the latter is heated, a very ingenious valve is provided, by means of which the pressure of the gas is relieved by the gas being separated from the water and collected in what is called a pressure-chamber. The water passes off mainly by gravity, and a very large proportion of the gas is thus retained. Dr. Roosevelt said that he had nothing to say as to the therapeutic effect of thus retaining carbonic-acid gas in waters used medicinally while heated.

The Chairman said that at Carlsbad and other places where heated mineral waters were used, the process of heating invariably drove off all, or nearly all, the gas which they contained when cold, and he believed that the retention of the gas by means of the apparatus described would therefore be of very great practical advantage.

A Clinical Study of Cocillana.—Dr. R. W. Wilcox read a paper on "Cocillana." He said that his studies in apomorphia, the results of which had modified his treatment of acute bronchitis and given him a clearer idea of the characteristics which an expectorant should possess, had led him to seek further to find one which should be effectual in doses of longer interval and without the addition of the bromide, which was frequently objectionable. In May of this year there was placed in his hands a supply of the concentrated tincture of cocillana. The source of this drug was the bark of an undetermined species of guarea, which was discovered in Bolivia in 1886 by the eminent botanist, Professor H. H. Rusby, of the College of Pharmacy, who first brought specimens to this city. The principal physiological action of the drug in its crude state (powdered bark) was the production of nausea and a desire to vomit, with metallic taste in the mouth within half an hour after its administration; this nausea being accompanied by an early discharge of mucus, and later by dryness of the throat. Its action, then, might be stated to consist of stimulation for some hours of the vessels and glands of the mucous surfaces, more especially of the respiratory tract, with subsequent diminution of activity (sedation).

The dose of the concentrated tincture of the bark used varied from one-half to two fluidrachms, given every two to eight hours. He believed, however, that the fluid extract, in doses of from five to twenty-five minims, at the above-mentioned intervals, would, on account of the avoidance of alcohol, be more satisfactory in acute, and, probably, in chronic diseases. Having made a comparison of the effects of the drug with those of apomorphia in acute bronchitis, he stated that the expectorant effect of cocillana was not the first stage of nausea, as was shown by the fact that an increase of appetite was usually observed even under the administration of full physiological doses, while the fulness of the pulse under them remained unchanged.

Useful in Chronic Dry Bronchitis. — Dr. Wilcox related a number of cases in which cocillana was used, and went on to say that it was probable that in subacute and chronic dry bronchitis we found the larger field for its employment. The facts that its expectorant effect was more sure than either apomorphia or ipecacuanha in liquefying bronchial mucus, that it increased the appetite, and that it acted to some extent as a laxative, perhaps by stimulation of the intestinal muciparous glands, all commended it to us. Further, expectoration was not so much influenced by warm diluent drinks as in the case of apomorphia, ipecacuanha, or carbonate of ammonia, although cocillana itself would produce a slight perspiration. In chronic bronchitis with viscid expectoration it would render the sputum liquid somewhat more surely than ipecacuanha, and it had the further advantage of not causing nausea. At times, also, the formation of mucus seemed to be checked. On the other hand, in cases of senile bronchitis, particularly in cases of calcified costal cartilage, it might so markedly add to the bronchorrhœa that it became absolutely dangerous, and particularly because it was not a stimulant to the respiratory centre, like belladonna and strychnine. In these cases, then, it was useful only so far as it liquefied secretion.

Also in Chronic Pulmonary Disease.—Having related another series of cases, he said that in chronic pulmonary disease it could be seen that cocillana had almost its only use in liquefying secretion and relieving the acute exacerbations of associated chronic bronchitis. Under its use the cough and expectoration diminished, and the night-sweats, inappetence, and constipation were relieved, and in general it might be said to be preferable to ipecacuanha. Naturally, when cough was due to pleuritic exudation, or was laryngeal or pharyngeal, cocillana would fail, as would all the other expectorants. In the latter instances he doubted whether local applications of the drug would be effectual.

In conclusion, he stated that he believed cocillana to be superior to apomorphia, except in cases of acute bronchitis, when taken within the first forty-eight hours. It was certainly preferable to ipecacuanha, in that it did not so readily cause nausea and metallic taste in the mouth, and, moreover, assisted regular movement of the bowels. It must yield to carbonate of ammonia in chronic senile bronchitis, although the heart-beat and pulse became stronger under its use; nor could it stimulate the respiratory centre like strychnia. It was immeasurably safer in any stage of acute bronchitis than pilocarpine, because it did not depress the heart's action. On the whole, he believed that it could fully replace ipecacuanha (which was now becoming expensive from exhaustion of the supply) in every sphere of action, and that in many cases it could be substituted with advantage for apomorphia, carbonate of ammonia, strychnia, and other drugs, classed with more or less reason as expectorants.

Dr. H. H. Rusby, of Newark, N. J., exhibited some of the bark of the plant and also herbarium specimens, showing some of the immature fruit. He said that while many of the observations recorded in the paper had been confirmed by others who had experimented with the drug, Dr. Wilcox's investigations upon certain other points relating to this new medicine had resulted in positive discoveries. It was his own practice, if a case of bronchitis came under observation early, to push the cocillana vigorously, giving from 15 to 45 drops of the fluid extract every hour for twelve hours, if necessary. At the end of six or seven hours it could usually be seen whether it was going to have the desired effect or not. He said that he became acquainted with the plant in Bolivia, where his attention was first directed to it by the accounts given of it by the natives. As soon as he could get the opportunity he commenced experimenting with it upon his friends, in doses of 20, 30, and 40 grains of the powdered bark, and he found that these accounts were for the most part fanciful. The natives, he remarked, knew of only two uses for drugs of any kind, viz., to produce emesis and to produce catharsis; and he learned that they sometimes gave the cocillana in such large doses as to destroy life by the vomiting and purging caused by it. He had anticipated that it would prove a very useful remedy in pharyngitis and laryngitis; but in this he had been disappointed, since it proved too irritating when given in sufficiently large doses to produce the desired effect upon the system.

Eye Symptoms as Aids to Diagnosis.—Dr. D. C. Cocks read a paper on "Eye Symptoms as Aids to Diag-

nosis." The indifference of a large number of medical men to the eye he believed to be due to a lack of appreciation of the important bearings that eye symptoms have on diagnosis and treatment. He therefore proposed to bring to the notice of the Section an outline of the more important facts about the eye and its diseases, a knowledge of which was essential or helpful in diagnosis. Diagnosis, he said, was sometimes made from one pathognomonic symptom; at other times it could only be made by the careful study of the symptoms for months or years. It was therefore evident that an organ such as the eye, which gave pathognomonic signs in some cases, and in others symptoms which proved to be the key to the situation, could not well be turned over to the specialist on all occasions.

Diseases of the Lachrymal Apparatus.—He first took up the diseases of the lachrymal apparatus. Epiphora, he said, was at times the first symptom of facial paralysis. The orbicularis failing to keep the puncta in contact with the globe, the tears flowed over the cheek. The presence of dacriocystitis indicated something more than a localized inflammation. It indicated probably an obstruction in the canal or sac, the most frequent cause of which was a neglected nasal catarrh; or, if this was excluded, exostosis and periostitis, the result of syphilis. Where the inflammation persisted, in spite of judicious treatment, some other constitutional trouble would sometimes be found to account for it, as, for instance, diabetes mellitus.

Herpes Zoster Ophthalmicus was pathognomonic of changes (probably inflammatory) in the fifth nerve and gasserian ganglion. It was frequently mistaken for erysipelas, although its situation, on one side of the head, should prevent this; while the persistent neuralgia which followed the disease could not satisfactorily be accounted for when the case had been diagnosed as erysipelas.

Morning Œdema of the Lower Eyelids.—He next alluded to the universally known symptom of Bright's disease, morning œdema of the lower lids, and then said that the reddened margin of the lids (blepharitis marginalis) indicated a lowered condition of the general system, as well as errors of refraction, chronic conjunctivitis, and muscular insufficiencies. Pediculi of the cilia were sometimes mistaken for this condition, but they were usually associated with others on the pubis. The primary lesion of syphilis was sometimes formed on the eyelid or its margin, and the history of an indurated sore of this region should be carefully investigated. Ptosis by itself might mean pressure by syphilitic or rheumatic swellings, a trauma (such as fracture of the apex of the orbit), or a nuclear trouble suggestive of general or posterior spinal sclerosis.

The Exophthalmos of Grau's Disease gave the diagnosis of this condition before the history was taken. Exophthalmos of both eyes might indicate the presence of œdema, and cellulitis of the orbit, associated with and dependent upon a thrombus of a cerebral sinus. When exophthalmos was limited to one eye we might have tumors of the orbit or its neighborhood, or a syphilitic periostitis, or even an orbital hemorrhage from whooping-cough.

Derangement of the Ocular Muscles.—In speaking of the derangements of the ocular muscles he said that as a rule they sympathized with the general system, and wonderful results were at times obtained by the relief of oculo-muscular strain, where this had been the exciting cause of various symptoms in nervous individuals whose health had been below par. The correction of insufficiencies by prisms or tenotomies would often give an entirely new aspect to cases that were formerly obscure. When all the external muscles of the eye were paralyzed we had ophthalmoplegia externa, a disease not of the eyes, but of the central nervous system, the nuclei of the third, fourth, and fifth nerves in the floor of the fourth ventricle and the aqueduct of Sylvius being implicated. A recurring paralysis of the fourth, or third, or sixth was frequently the first indication of spinal sclerosis or of a general sclerosis. The nerves which supplied the ocular muscles traversed the cranial cavity for such a distance that, frequently, the first symptom of a basilar trouble or intracranial disturbance was evinced by the paralysis of one or more of the muscles supplied by these nerves; and the progress of morbid growths could often be watched by successive muscles being involved, and the exact location of the neoplasms thus accurately marked out. The nature of the diseased condition also could often be diagnosed by the grouping of symptoms, aided by the condition of the muscles.

The conjunctiva afforded many suggestions to the observant practitioner. Having referred to its condition in various febrile diseases, he stated that phlyctenular conjunctivitis was almost always indicative of lowered health, of eye strain, or of unsanitary surroundings. Chronic conjunctivitis had about the same significance, but was also associated with nasal or pharyngeal catarrh. Subconjunctival hemorrhages in pertussis were indicative of the presence of some paroxysms, while in the adult they seemed to have no pathological significance. An indurated ulcer of conjunctiva, as of the lid, might mean, and often was, the initial lesion of syphilis.

Phlyctenular Keratitis indicated eye strain, either with or without reduced health and unsanitary surroundings; and chicken-pox, measles, and scarlet-fever sometimes preceded this trouble. Interstitial or diffused keratitis was indicative of some constitutional trouble, and in a large proportion of cases it occurred in the young and was due to congenital syphilis. A smaller percentage of cases were due to secondary syphilis, and still others to some other form of dyscrasia, such as latent or hereditary gout. The presence of keratitis with hypopyon indicated the presence of infection from some quarter, possibly nasal catarrh, dacriocystitis, or carious teeth. In those cases where the cornea sloughed away without pain or distress in old people, we might know that their vital powers are much depressed, and their blood-vessels probably atheromatous. When the cornea was found to be cloudy or ulcerated, while the patient complained of no pain or photophobia, we had a keratitis due to a lesion of the fifth nerve. Sclerotitis and episclerotitis rarely occurred except rheumatism or the rheumatic diathesis was present; and Dr. Cocks said that he had now a lady under observation in whom this was the only symptom of rheumatism, and it was yielding to anti-rheumatic remedies, while her general condition was also improving.

Affections of the Iris.—Next, as to the iris. When we were confronted with an attack of iritis it was necessary that we should look for the cause of the inflammation, and an enumeration of the constitutional conditions which might give rise to iritis would show how important it was to make a thorough investigation of each case. Among those referred to were hereditary, secondary, and tertiary syphilis, gonorrhœa, malaria, variola, tuberculosis, rheumatism, and gout. At a recent meeting of the New York Ophthalmological Society he had reported a case of tubercular iritis, in which Dr. Richmond Lennox demonstrated microscopically the presence of tubercle bacilli, and then an examination of the child showed the presence of a phthisical process in progress within the chest. In his experience it was the presence of some one suggestive symptom that had often led to a diagnosis, where otherwise the case would have remained unsolved.

Condition of the Pupil.—After some remarks on the condition of the pupil in various affections, he said that in complete paralysis of the third nerve there were mydriasis and paralysis of accommodation, and that he had had under his care cases of diphtheria which were not recognized as such until dilatation of the pupil and paralysis of accommodation had occurred. The existence of mydriasis, together with other symptoms, might clear up a doubtful case of cerebral tumor or of syphilitic trouble of the base, or be indicative of a fracture through the apex of the orbit. Headaches not yielding to ordinary treatment might be due to weakness of the ciliary muscle, and the recognition of this condition would lead to its cure.

Ophthalmoscopic Signs.—Dr. Cocks next passed to the interior of the eye. The ophthalmoscope, he thought, should be in the hands of every practitioner, and as illustrating the facility with which a knowledge of its application might be acquired, he said he had had medical students clearly describe the fundus of the eye after one lesson. A choroiditis of the macula of each eye, occurring together or consecutively, attended with numerous dust-like specks in the vitreous, was almost pathognomonic of syphilis, either congenital or acquired. Its early recognition was of the utmost importance to the patient, and as the changes could be readily seen (when looked for) he had a right to feel aggrieved if his central vision was lost through neglect. That terrible lesion, metastatic choroiditis, so destructive to the eye, and at times to the lip, might occur in puerperal fever, in pyæmia, in typhoid fever, and in cerebro-spinal meningitis. In regard to the normal fundus he would say that its negative value in diagnosis could only be appreciated by those accustomed to look to the ophthalmoscope for aid; and in this connection he referred to a case of recent blindness, in which, after an examination of the urine, he was enabled to make the diagnosis of uræmic amblyopia by reason of the fundus being normal. A rapidly forming or soft cataract might be the first symptom that attracted attention to the presence of diabetes mellitus; while the existence of a soft opaque lens, with a scar in the cornea, besides proving that an injury had been inflicted, might also indicate the presence of a foreign body in the eyeball which required immediate attention.

Intra-cranial Changes.—Probably the most interesting part of this subject was the light thrown on intra-cranial changes and on general diseases by changes in the retina and nerve. The neuro-retinitis of Bright's disease, with its accompanying and almost pathognomonic changes in the neighborhood of the macula, were well known; and one of sufficient importance to demand the attention of every physician. Having referred to the retinitis of syphilis, he said that optic neuritis, especially if double, was one of the greatest aids to diagnosis, and related an illustrative case in which the patient suffered from vomiting and slight headaches, with vertigo at times, and in which, after careful examination, he pronounced the condition ophthalmoplegia externa, and the lesion, therefore, nuclear. Shortly afterward, however, he found double optic neuritis, which overthrew the nuclear theory, and established that of a slowly growing neoplasm. Atrophy of the optic nerve was one of a series of symptoms which might prove the previous existence of cerebro-spinal meningitis, basilar meningitis, gumma in the same region, alcoholism, fracture of the base of the skull, with involvement of the apex of the orbit, or tumor of the base pressing on the nerve or chiasm.

Disorders of Vision.—In speaking of disorders of function he said that a central scotoma for red was almost pathognomonic of tobacco-poisoning. Night-blindness occurred in commencing atrophy of the optic nerve, in extreme cases of anæmia from fasting, and in retinitis pigmentosa. Word-blindness, as a rule, accompanied lesion of the cortex cerebri; while acquired partial or complete color-blindness was indicative of nerve atrophy. Limitation of the field of vision was found in optic atrophy, glaucoma, and retinitis pigmentosa. When monocular hemianopsia existed, the condition was probably one of intra-ocular lesion, as of detached retina, etc., but when binocular hemianopsia was present, an intra-cranial lesion certainly existed, and this lesion was along the optic tract or in the occipital lobe of the same side as the loss of vision.

Sudden Blindness in Bright's Disease.—In conclusion he alluded to two points. In Bright's disease the patient sometimes suddenly became completely blind without a lesion of the fundus. The difficulty in such cases was evidently central, and due, in all probability, to œdema of the centres; for it should be distinguished by the aid of the ophthalmoscope from the loss of sight due to albuminurial retinitis. Acute glaucoma was sometimes mistaken for a bilious attack or hemicrania, and chronic glaucoma for incipient cataract. Here the increased tension of the eyeball, the dilated and immobile pupil, the limited range of accommodation, and the contracted field would soon settle the diagnosis, even without the aid of the ophthalmoscope, were these signs looked for.

Discussion.—Dr. H. D. Noyes said that the particular significance of the paper was its advocacy of a closer affiliation between the eye-specialist and the general practitioner. He regarded it as a great misfortune that in every specialty the tendency of the work was to narrow the field and shorten the view of the physician devoting himself to it; and if it should follow as a result of Dr. Cocks' paper that general practitioners should less frequently than now omit to make an examination of the eye, when this was called for in the course of their daily work, he believed that it would have accomplished a most excellent purpose. The whole subject, he thought, had been admirably presented in the paper. The range of affections in which the eye was concerned, to a greater or less extent, was immensely large. Not only was it connected with those of the entire cerebro-spinal nervous system and the peripheral nerves, but also with remote organs and the condition of the blood.

Pernicious Eye Symptoms in Anæmia.—Having referred to the eye symptoms met with in pernicious anæmia and diabetes mellitus, he stated that one of the latest contributions to our knowledge of this subject was the demonstrated fact that acute myelitis was able to give rise to lesions within the eye. In this connection he mentioned a case reported by Dr. E. C. Seguin, to the study of which he had himself also contributed, which was the first on record in which the results were confirmed by post-mortem examination. The autopsy showed that the central fibres were affected throughout. During life there had been a singular affection of the sight, and it was found that there were spots of inflammatory softening along the tractus opticus on one side only, while there was a small focus of inflammatory trouble in the papillæ of both optic nerves.

Dr. Noyes went on to speak of the implication of the ocular muscles, the impairment of accommodation, such as occurs in diphtheria, and certain appearances of the retina, and said, in conclusion, that, working as he did, constantly in a comparatively narrow field, he had often felt a sense of lonesomeness, of isolation from the rest of the profession. If, now, it could be brought about that the specialist and the general practitioner would not hold themselves so far apart from each other, he thought great good would result, not only to the community at large, but to the cause of medicine.

Dr. J. E. Weeks said that he entirely agreed with Drs. Cocks and Noyes, that if the general practitioner would make himself more familiar with eye symptoms, the community would be greatly benefited. It was not necessary that he should make himself acquainted with all the minute details of ophthalmic pathology (which, indeed, would require years of study), but he should at all events be familiar with certain symptoms constantly liable to be met with, by the early recognition of which the most serious consequences could sometimes be avoided. In illustration he mentioned the case of a gentleman residing in a neighboring town, who suffered very greatly from neuralgia, and was finally sent to New York for examination. Here it was found that he had already irretrievably lost his eyesight by glaucoma. Any neuralgic pain which was not clearly understood should, at least, awaken the apprehension of the attending physician, so that any such calamity as this might be averted, if possible.

The appearances of the lids sometimes were indicative of systemic conditions, and he had known the diagnosis of nasal diphtheria to be made in this manner. The diphtheria of the nasal passages had resulted in diphtheritic conjunctivitis, and if the attending physician had been familiar with the appearances of the latter, the diagnosis could have been made much earlier, and the life of

the patient (who died of the disease), might, perhaps, have been saved. It was only the grosser appearances of the eye in various conditions that it was necessary for the general practitioner to be able to recognize.

Ophthalmoscopic Examinations.—Dr. W. F. Mittendorf thought that since we had at our command such a mydriatic agent as cocaine, and since the ophthalmoscope was now so perfect an instrument, there was really no excuse for not examining the fundus when light was needed on a diagnosis, and he felt sure that if physicians in general would take the trouble to familiarize themselves with the use of the ophthalmoscope, they would find it, not only profitable but exceedingly interesting. He referred to interstitial keratitis as an indication of congenital syphilis, and in speaking of the retina, said that while sudden blindness was liable to occur sometimes in connection with disease of the kidneys, it occurred more frequently in cardiac troubles.

Cereberal Hemorrhage with Usual Difference in Size of Pupils.—Dr. Andrew H. Smith said that, as illustrating the point that sometimes a single symptom will enable one to make a diagnosis, he would relate a case which occurred some years ago, when he was attending physician to St. Luke's Hospital. A gentleman in one of the private rooms, suffering from some acute trouble, had so much pain one night that it was necessary to give him two hypodermic injections of morphia before he could be relieved. Some time after the second injection the patient was found to be in a state of coma, and the house physician, supposing that he was one of those individuals sometimes met with whose systems are abnormally affected by narcotics, naturally attributed the condition to the morphia. Dr. Smith was hastily sent for, and on arriving at the hospital he found that all the preparations had been made for a vigorous campaign against opium-poisoning. Before resorting to any active measures, however, he made a careful examination of the patient, and the first thing that struck him was the fact that the pupils were not so contracted as they would have been in the latter condition. He noticed, moreover, that there was some difference in the size of the two pupils, and that there was a deviation of the axis of one eye. In consequence of these appearances in the eyes an expectant treatment was adopted, and it now became evident that the patient had had an attack of cerebral hemorrhage, from which, indeed, he died the next morning. But for the information derived from an examination of the eyes, he would have been subjected to flagellation and the other ordinary active measures employed in narcotic poisoning.

Dr. Noyes, he said, would no doubt remember a case which he had seen with him, where the patient, in addition to a nervous twitching of the hand, something like writers' cramp, and a slight paresis of the leg, suffered from occipital pain, which appeared to be brought on by straining the eyes in reading. Under the use of the glasses prescribed by Dr. Noyes, not only was the occipital pain cured, but the trouble in the hands and legs was also very greatly relieved.

Dr. T. R. Pooley said that the paper of Dr. Cocks covered all the classes of cases in which eye symptoms were of service to the general practitioner in the way of diagnosis. There were some points, however, in which he could not agree with the reader. For instance, in his experience he had found that atrophy of the optic nerve in cerebro-spinal meningitis was not at all common. The disease of the eye which was most frequently met with in this affection was purulent choroiditis, and from this there generally resulted atrophy of the globe. He then went on to call attention to the significance of intra-ocular hemorrhage. This occurred, he said, where changes, either atheromatous or syphilitic in character, had taken place in the arteries; and where retinal hemorrhage was observed the chances were very strong that hemorrhages would occur elsewhere also. He regarded this as a very important point; so important, indeed, that whenever the retina showed this condition he believed it was the duty of the oculist discovering it to call the immediate attention of the regular medical attendant to it, since such a patient was liable to have intracranial hemorrhage at any moment.

Inadequacy of Ocular Muscles and Exhausting Diseases.—There was one thing that Dr. Cocks had said that was worthy of special attention, viz., that inadequacy of the ocular muscles may be due to exhausting disease of any kind. It was just now the fad to attribute immense importance to such inadequacy, and to perform repeated operations for the relief of the same. If many of these cases were left to themselves, or, what was better, if the patient were treated for his general condition by a sensible and intelligent family physician, the insufficiency of the ocular muscles would entirely disappear of itself. What such a patient needed was proper attention to his general health, and not special treatment from an oculist. He did not, however, of course, mean to say that cases did not sometimes occur which required to be treated by prisms, or even by tenotomy. As to the effect of general disease in producing asthenopia, he said that he desired to call special attention to uterine disease in this connection. In only a very small proportion of these cases of asthenopia was there any error of refraction; and the deficiency in accommodation would generally disappear under treatment appropriate to the general condition of the patient.

The Chairman said he heartily agreed with Dr. Pooley as to the great diagnostic significance of retinal hemorrhage. A year ago he was treating an officer of the United States Army, who was staying at the Sturtevant House, in this city, for Bright's disease. Dr. Loomis had been called in consultation, and the case was believed to be progressing very favorably, marked improvement having been shown. The patient was about to start for the South; but as he complained of some difficulty in his eyesight, it was deemed best, before leaving, to have his eyes examined by a specialist. Dr. David Webster was accordingly called in, and he found that the trouble was due to retinal hemorrhage. He also expressed the opinion, based on the condition revealed by the ophthalmoscope, that the patient was liable to die at any time from cerebral hemorrhage; and the correctness of this opinion was attested by the fact that he did die from this cause within twenty-four hours.

General Practitioners should watch Eye Symptoms.—In closing the discussion, Dr. Cocks stated that his object in writing the paper was to impress upon every general practitioner the importance of looking at the eyes of his patients. He had again and again heard physicians say: "I know nothing about the eye." It was their business, however, to know something about it, and he believed that no one could be fully equipped for the practice of medicine without this was the case. He did not mean that the general practitioner should be a specialist, but that he should have a general knowledge of those conditions of the eye which were associated with various diseased conditions in other parts of the body. Hence he did not believe that physicians were doing their whole duty to their patients in simply referring them to a specialist when any symptom about the eye attracted their attention. In conclusion, he referred to the differential diagnosis between glaucoma and cataract by means of the ophthalmoscope.

Treatment of Gonorrhœa by Sea-water.—Dr. R. F. O'Brien reports in the *British Medical Journal*, November 30, 1889, a number of cases of gonorrhœa treated by means of injections of sea-water. He had the injections given seven or eight times in the twenty-four hours, each injection being retained for a few minutes. The average duration of the disease under treatment was 8.87 days. In addition to the injections, the general treatment consisted in rest, dieting, saline aperients, and the avoidance of stimulants.

PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, December 6, 1889.

DR. FRANCIS P. KINNICUTT, PRESIDENT, IN THE CHAIR.

New Method of Opening the Brain.—DR. DANA showed a specimen illustrating "A New Method of Opening the Brain." The common method of opening the brain was Virchow's. As ordinarily carried out, this left the brain so mutilated that its subsequent preservation as a whole was impossible. Besides, the cuts were longitudinal, and, for immediate inspection as well as for subsequent microscopical examination, such cuts were very bad.

The method employed by the speaker was to make a single longitudinal cut through the corpus callosum, and the roof and floor of the fifth and third ventricles, entirely separating the two hemispheres and opening up the lateral third and fifth ventricles. The longitudinal cut is then continued through the corpora quadrigemina down to the aqueductus, and through the middle lobe of the cerebellum, laying open the fourth ventricle and aqueductus. Transverse incisions are now made in the cerebral hemispheres, beginning anteriorly and on the median surface.

These incisions are carried just to the cortex, but not through it, and they are made as closely together as was deemed necessary. The speaker described the levels used by himself. In finding the exact location of hemorrhages, and in determining the relations of the parts, he found this method vastly more satisfactory than the older one, and he very much wished that it might be generally adopted. It was not a new method, except in the essential point of leaving the cortex uncut, and in a few minor details.

Pachymeningitis Hæmorrhagica. — Dr. Dana also presented a specimen of "Pachymeningitis Hæmorrhagica." He said it was not a particularly rare lesion in his experience, although it was put down in many text-books as being only a pathological curiosity. He had seen three cases within a year. The one presented was rather interesting in connection with the symptoms. The patient, a woman about fifty years of age, was a chronic alcoholic, and entered the Bellevue Hospital in a state of alcoholism. Although she had not taken any liquor for several days, yet she lay in the state which usually characterized chronic alcoholics. She was stupid, and partially unconscious at times, and occasionally showed muttering delirium. She took food with difficulty, answered only a few questions, had no special fever. She continued this way about a week, and died of symptoms of pulmonary œdema and exhaustion. There was no sign of paralysis at any time. At the post-mortem he found a very typical form of pachymeningitis hæmorrhagica affecting the convexity of the right hemisphere. The dura showed at least four different fibrinous layers, indicating that there had been, at different times, as many as four effusions of blood with organization of the clot. The symptoms had resembled very much those of so-called wet brain, or œdematous brain. That had been his diagnosis, with, perhaps, a low grade of meningitis such as characterized alcoholism.

He believed it was beginning to be an accepted fact that these forms of meningitis were due to disease of the blood-vessels of the dura mater, perhaps very much like that which affected other blood-vessels of the brain in old alcoholics, syphilitics, etc.; that these vessels ruptured, a layer of clot formed which organized, the newly formed vessels in these clots again rupturing, and so on.

Cerebellar Hemorrhage.—Dr. Dana further presented two cases of "Cerebellar Hemorrhage." J. S——, aged sixty-one, laborer, admitted November 16th, 4 P.M., died at 5.45 P.M. Had been well, and was working, when suddenly fell down in an apoplectic stroke. He had no convulsion. He was brought to the hospital at once. He was unconscious, his breathing was labored, but not strictly stertorous; it soon assumed the Cheyne-Stokes character. There was no puffing-out of one cheek, as in ordinary cerebral hemorrhage. The pulse was about 100, hard, full, irregular. The eyes looked straight forward, but the head was inclined to turn to the left. There was a slightly greater resistance to movements of limbs on right side than on left, but not distinct evidence of paraplegia. The coma was so great, however, that positive determinations were impossible. There was no vomiting. The urine was drawn, and shown to contain considerable albumin.

The post-mortem revealed hemorrhage into the left cerebellar hemisphere, probably due to rupture of a branch of the superior cerebellar artery, the branch which goes to the dentated nucleus.

The second case was in a man about forty years of age, who was sent to a cell as an alcoholic, and it was therefore inferred that he must have shown some symptoms of ataxia and inco-ordination, as well as mental confusion. There was no paralysis, no hemianæsthesia, no evidence of central nervous lesion. He was in a cell a few hours, when he rapidly developed stertorous respiration, and died.

The post-mortem revealed a blood-clot in the posterior part of the middle lobe and a part of the right hemisphere of the cerebellum. This clot had burst into the fourth ventricle. The patient evidently had this clot when he entered the hospital, but it had not yet burst into the fourth ventricle. When the accident did occur, some hours later, it caused death. Dr. Dana thought it likely that his apparent alcoholic condition was due to this hemorrhage into the middle lobe of the cerebellum. Clots in the lateral lobe did not necessarily produce any change, but when they took place into the middle lobe one would expect some disturbance of that kind. He had looked over the records of the hospital, and had found that cerebellar hemorrhage had not been so very frequent. Among about fifteen cases of cerebral hemorrhage occurring in two years there were two in which the cerebellum was affected. He did not know whether that was the usual proportion, but he presumed it was not far from it.

DR. G. L. PEABODY said he would have to differ from Dr. Dana in his condemnation of the Virchow method of opening the brain. It seemed to him that there was less liability to overlook lesions of the white matter in that method than in his. Nor had he found Virchow's method one which distorted the brain, or prevented hardening the brain, or localizing lesions afterward. No portion was detached, and the brain could be folded up again like the leaves of a book. It seemed to him that it would be very difficult to improve upon.

Pachymeningitis Hæmorrhagica.—Regarding the frequency of pachymeningitis hæmorrhagica, he thought it was far more frequent than was commonly supposed. He had seen it a great many times, and in some cases in which it had not been suspected at all. Some had simply given a history of more or less headache, some had given no history whatever, and yet had died from rupture of the thin-walled, newly-formed blood-vessels. One who had had one attack was likely, on account of the thin walls of the newly-formed vessels, to have other attacks.

DR. V. P. GIBNEY said the case of pachymeningitis recalled one which he had treated very assiduously for several weeks, two years ago, under the impression that it was a case of tubercular meningitis. The boy had suffered from prolonged suppuration; had enlargement of the liver; gave a family history of phthisis; and for these reasons the head symptoms were believed by those who saw him to be due to tubercular meningitis. He recovered, but died about two years subsequently, when Dr. Gibney and Dr. Janeway made an autopsy, and found extensive pachymeningitis. There was no evidence of previous tubercular meningitis, although, as stated, the boy had shown a train of symptoms supposed by those who saw him to belong to the different stages, except the last one, of tubercular meningitis.

DR. ROBINSON inquired whether it was possible to make anything like a definite diagnosis of pachymeningitis before death.

Dr. Dana said he thought it was very difficult, the symptoms taking such various forms. Sometimes one observed hemiplegia, and symptoms very much like those of subcortical hemorrhage. Sometimes they took a course much like in an alcoholic subject. He had seen cases in which there were convulsions, and others in which there were none. He thought the main factors in the diagnosis related to the etiology. The cases were usually seen in pretty old people, or alcoholics, or the insane. If a person were not insane, were not alcoholic, and was of middle age, those factors would tend strongly to exclude pachymeningitis hæmorrhagica.

Dr. A. H. Smith asked whether he would include syphilitics.

Dr. Dana replied that he thought both syphilitics and alcoholics were to be included.

Dr. Peabody thought one was not likely to have an acute lesion of the interior surface of the dura mater without having a great deal of acute pain. That, he believed, was a factor almost always present in the class of cases under discussion, while it was not likely to be present in any marked degree in ordinary apoplexy. If with evidence of a cortical lesion there was a sudden development of acute pain (not gradual and progressive) of non-specific type, taking place in an elderly subject, he would say that the chances were rather in favor of pachymeningitis hæmorrhagica. He would not put it stronger than that.

Dr. Dana, in reply to Dr. Peabody, said that in skilful hands, no doubt, the Virchow method answered. But for ordinary routine use it was a bad method and was fundamentally defective, in that it left the brain sliced longitudinally instead of transversely.

Operation for Stenosis of Pylorus.—The President reported the condition of a patient eighteen months after "Loreta's operation for cicatricial stenosis of the pylorus." The case referred to had been published by Dr. William Bull and himself, twelve months after operation. On the first of the present month the patient's weight was one hundred and seventy pounds, a gain of thirty pounds since leaving hospital. His general condition was excellent, and he was able to pursue his usual vocation. On an ordinary mixed diet, with the exclusion of "sweets," he suffered from no distress of any kind during digestion at present, with the exception of occasional "heart-burn." There was a tendency to constipation, which was easily corrected by a mild saline laxative. The dilatation of the stomach, as estimated by filling and emptying the organ by means of the stomach-tube and noting the lower limit of dulness when full, was found to be the same as six months previous. The President believed that little further change in this respect was probable, the continued dilatation being due to overstretching of the stomach during a long period before the operation, and not to any present stenosis. The latter condition seemed very improbable in view of the present digestive power and the condition of the patient.

The Therapeutics of Typhoid Fever.—Dr. George L. Peabody read a paper entitled "A Contribution to the Therapeutics of Typhoid Fever." He said the results in the treatment of typhoid fever continued to be so bad in general, in this country, as to constitute a chronic opprobrium to the art of medicine here. We did not seem capable of approaching, at least in New York, the low rate of mortality which had rewarded the efforts of the medical profession in many cities of Europe; it was not sufficient explanation to say that we had a larger percentage of bad cases. He believed, too, that the fact that we had not yet arrived at anything at all resembling a general consensus of opinion regarding its treatment was further evidence that very many cases must be improperly treated, and that thus much of our high mortality was to be accounted for. Those who still adhered to the expectant plan of treatment were in the large majority here. In this plan practically nothing was done unless symptoms in themselves disturbing or grave, or even threatening, developed, and then much was often done that was likely to be pernicious. Doctors of this class seemed to be pretty well in accord as to the proper plan of procedure, and to believe that a simple symptomatic treatment was the rational one. If the patient had headache he received the bromides, or an ice-cap, or both. If a bronchitis developed he was given opium, or cough mixtures, or inhalations; if hemorrhage from the bowel occurred, to opium was added tannic acid or gallic acid, or some other equally useless or disturbing drug; and so on. But most pernicious of all, if his temperature reached what was considered a dangerous height, an elevation which, if long continued, would become incompatible with life, he was given a large dose of some antipyretic drug, and the temperature was suddenly reduced perhaps several degrees below normal. Often this objectionable procedure was repeated in an almost rhythmical way for several days or weeks; and if, accompanying the fall of temperature thus produced, there were a degree of prostration and feebleness of the heart which was alarming in itself, then to counteract this bad symptom, for which the drug and the doctor were responsible, alcoholic and other stimulants were given in large amount. This method its advocates dignified by the appellation *rational*. Dr. Peabody thought it would be difficult to devise a more *irrational* method than the *symptomatic* one carried to its logical issue. It would be quite as proper to treat perityphlitis symptomatically, giving purgatives for the constipation; and in any disease, withholding food or drink because the patient might have no appetite or thirst.

Unfortunately, those of us, on the other hand, who believed in treating the disease upon some other and more definite system, were very far still from being in accord as to the best method to pursue in the average case. One possessed of any facts bearing on the therapeutics of this disease need offer no apology for presenting them.

During the past year it had fallen to the reader's lot to treat about fifty typhoid patients, chiefly in the New York and Bellevue Hospitals. It would be premature to say the results were due to the treatment, inasmuch as this number was small. They were in the main satisfactory. The fever prevailing last year seemed of less severe type than usual in New York; this year it seemed fully up to the average degree of severity.

Antisepsis.—Last year he had made systematic trial of treatment by antisepsis, resorcin and beta naphthol being used in the New York Hospital. These drugs were given in full form, and always coated with keratine to insure them against effects of stomach-chemistry. When the patients entered the hospital within the first ten days of the disease, the routine method was to administer a calomel purge of ten grains, and immediately follow it by a dose of one of the antiseptics, which was repeated at varying intervals day and night, as a rule, until the temperature became normal and remained so. Thirty-three well-marked cases of this disease came under his care in the New York Hospital last year, and of these twenty-seven were treated antiseptically. But little use was made of any of the newer antipyretic drugs, though in some cases occasional doses of phenacetine were administered, but formed no part of the treatment.

He remarked that the effects of the antiseptics upon Ehrlich's reaction were interesting. This reaction, even though it might have been ever so plainly present when the patient began treatment—and it was so almost invariably—usually disappeared after the first few doses, and remained constantly absent while the drug was being given. It promptly reappeared if the drug were stopped during the pyretic period.

Beta Naphthol.—Of unpleasant consequences of beta naphthol he had to record the occurrence of blood, albumin and casts in the urine in a few patients, which, however, disappeared promptly when the drug was stopped. Resorcin produced absolutely no unpleasant effects.

The effects upon the temperature and duration of the disease seemed sometimes quite unmistakable, and to be

about the same with either drug. In six cases the fever lasted seventeen days or less, in three it lasted only two weeks, in nine it ceased entirely in just three weeks from the date of commencement. In the other cases it lasted generally about four weeks, and did not seem to be materially influenced by the treatment. Five of the twenty-seven patients died, but of these one was under treatment only one day, two only two days, and a fourth only six days. Death was due in one case to extensive ulceration of the colon, with profuse and wasting diarrhœa, in one to profuse hemorrhage, in one to lobar pneumonia, and in two to parenchymatous nephritis. The two latter were treated by beta naphthol and resorcin, respectively, one and six days, and in consequence of its short duration the treatment could hardly be considered the cause of this grave symptom. The height of the fever seemed to be more markedly affected than its duration, and the comfort of the patients was proportionately promoted. Usually it ranged between 100° and 102° F. Milk was always the chief, and usually the only, food.

Antipyretic Effect of Cold Water.—The author said it would be a source of great regret to him to give the impression that he considered this method of treatment as worthy of comparison with the antipyretic method, *i.e.*, the antipyretic effect of cold water applied to the surface of the body. It seemed to him that anyone at all open to conviction by statistics could not but admit that the recent statistics of Brandt, as quoted by Professor H. C. Wood in a recent edition of his text-book on therapeutics, made a marvellously good showing for the cold-water treatment. Unfortunately, two apparently unavoidable facts strongly militated against as good results from this form of treatment here as were obtained in Germany and Austria. Patients here entered the hospitals later, scarcely ever in the prodromal stage, and we had a constantly shifting attendance of doctors, house-staff, and nurses. In the face of these discouraging facts, he had lately been trying to accomplish the principle of Brandt to a certain extent by other means than the cold bath. They received into Bellevue Hospital a considerable number of patients suffering from typhoid fever, but they were largely from the poorly-fed, badly-nourished, and intemperate classes, and they usually came under treatment late in the disease. Many of them did not bear the cold full-bath well; the depression which it caused seemed to be too profound, and the reaction slow. Accordingly, he had been trying to keep the temperature of these patients constantly at or below 102° F. by the cold pack, however frequently it might be necessary to apply it. Only occasionally was one encountered in whom the pack, when properly applied, was not capable of causing a prompt reduction of temperature. In that event a small dose of an antipyretic drug was administered. Large doses should not be given. Used in small and frequent doses, to supplement the effect of the cold pack, he believed they became of distinct value. The cold pack proved rarely necessary oftener than four or five times in the twenty-four hours, in keeping the temperature under 102° F. During the past few weeks he had subjected eleven cases in Bellevue Hospital to treatment by the cold pack, with very satisfactory results. All recovered. All were adults, most of them made up of poor material; in most the temperature had been persistently high; they came under treatment late in the disease, that is, after it had lasted two weeks or longer. It was a matter of greater importance than was commonly supposed that these patients should not be kept too warmly covered in the intervals between the packs.

On the whole, the method of treatment by the wet pack had been more gratifying to him than that by the internal use of antiseptics; but he wished again to emphasize the importance of using it systematically, and so frequently as to keep the temperature always below 102° F.

[The interesting discussion which follows this paper will appear in our next issue.—ED.]

(To be continued.)

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from December 29, 1889, to January 4, 1890.

JARVIS, NATHAN S., First Lieutenant and Assistant Surgeon. By direction of the Secretary of War, par. 1. S. O. 180, December 6, 1889, Department of the Missouri, transferring him from Fort Lewis, Col., to Camp Wade, Kingfisher, Indian Ter., is confirmed. Par. 6. S. O. 303, A. G. O., December 30, 1889.

MEARNS, E. A., Captain and Assistant Surgeon. By direction of the Secretary of War, the leave of absence granted him in S. O. 244, October 19, 1889, from this office, is extended two months. S. O. 303, A. G. O., December 30, 1889.

POWELL, JUNIUS L., Captain and Assistant Surgeon. By direction of the Secretary of War, ordinary leave of absence for two months is granted him, in extension of the leave of absence on account of sickness granted him in S. O. 258, November 5, 1889, from this office. Par. 1, S. O. 1, A. G. O., January 2, 1890.

CAHILL, JULIAN M., First Lieutenant and Assistant Surgeon. By direction of the Secretary of War, the leave of absence granted him in S. O. 249, A. G. O., October 25th, is extended one month. S. O. 304, A. G. O., December 31, 1889.

Official List of Changes in the Medical Corps of the United States Navy for the week ending January 4, 1890.

CLARK, JOHN S., Medical Inspector. Ordered to the Baltimore.

DIEHL, OLIVER, Passed Assistant Surgeon. Ordered to the Baltimore.

STILT, E. R., Assistant Surgeon. Ordered to the Baltimore.

SMITH, HOWARD, Surgeon. Ordered to the Alliance.

GATEWOOD, J. D., Passed Assistant Surgeon. Ordered to the Despatch.

TRYON, J. R., Surgeon. Ordered to the Naval Medical Examining Board.

SCOFIELD, W. K., Medical Inspector. Ordered to special duty at New York City.

GUITERAS, D M., Passed Assistant Surgeon. Ordered to the Naval Hospital, Philadelphia. Pa.

A Vigorous Centenarian.—There is living in Bolivar, Pa., an old gentleman, named William Reese, who was born in England on June 15, 1778. He has always enjoyed excellent health, the only illness that he can recall being a slight attack of sciatica a few years ago. His hearing is impaired, but his eyesight is still good, and he can read without the aid of glasses. He was always very temperate in every way, having made it a rule to rise from the table unsatisfied, and although he is a pretty constant smoker, his method is to go out on the porch for a few whiffs and then return to his seat at the fireside. He is a very interesting old man to talk with, and steadily declines all assistance but that of his cane in going about. His father and grandfather are both said to have lived to be over a hundred years old, and his mother also had passed the century line at the time of her death. He has had five sons and five daughters, all of whom lived to maturity, but the special strength of constitution seems to have been inherited only in the male line. Of the sons but one is dead, and he was killed in the war, while of the daughters three are dead, one from phthisis, another from cancer of the breast, and the third from ovarian cyst.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending January 4, 1890.

	Cases.	Deaths.
Typhus fever	1	0
Typhoid fever	11	7
Scarlet fever	75	11
Cerebro-spinal meningitis	1	1
Measles	37	7
Diphtheria	95	31
Small-pox	0	0
Varicella	0	0
Cholera	0	0

The Epidemic Influenza—Report of the Committee on Hygiene of the County Society.—When reports on the "Grippe," which tended to alarm the public, began to appear in the newspapers, the Chairman of the Committee on Hygiene of the County Medical Society, Dr. S. Baruch, called the members together for the purpose of discussing measures for allaying public alarm, and at the same time investigating the true status of the epidemic. The Chairman thought that the large number of deaths reported was probably due, indirectly, to the influence of the epidemic upon the numerous cases of chronic disease which in every large community are hovering at the brink of the grave, and he asked the Committee to take whatever steps they thought proper in the premises. It was resolved at the first meeting to request Dr. Hunter to call a meeting of the County Society, to which alone the Committee is responsible. Upon a conference between the Chairman and Dr. Hunter, a change was decided upon, which, being submitted to the Committee, was adopted, viz., to invite a number of active practitioners to a conference at the house of the Chairman, 47 East Sixtieth Street, to discuss the subject of Epidemic Influenza. The discussion was entered into by Dr. Lewis Smith, Dr. Hunter, Dr. Rodenstein, Dr. Tuttle, Dr. Lustgarten, Drs. Chapin, Emerson, Page, and the Chairman. The contagiousness of the disease was thought probable by Drs. Smith, Tuttle, and Lustgarten. Its specific character presenting all evidences of an infectious disease was universally accepted. The various types presented by the epidemic were of interest. Drs. Chapin and Baruch cited cases of children, each one case, in which it was initiated by a convulsion. Dr. Baruch reported two cases with an erythematous, and one with a papular, eruption; gastro-intestinal disturbance was referred to by Dr. Hunter. Dr. Chapin thought that we may distinguish one type as an acute febricula. There was a consensus of opinion with regard to a tendency to lower the vital powers in nearly every case. Purgatives had produced faintness, and Dr. Page dwelt especially on distinct evidence of heart-failure in many cases. Dr. Hunter reported three deaths, one in a case of chronic fatty heart, and two in cases of chronic bronchitis. It was the opinion of the gentlemen present that, up to the present time, the epidemic does not present alarming features. There are certain phases of it, however, that tend to develop bronchitis and pneumonia. A prominent characteristic of the disease, the tendency to lower the vital powers, calls for great caution on the part of those attacked to avoid exposure and fatigue during convalescence. The ubiquitous reporters, whom the Committee had thought to escape by changing the place of the meeting from the Academy to the residence of the Chairman, discovered the plot, and insisting upon obtaining the results of the discussion, were furnished the "opinion" above given.

Vaccination on the Congo.—It is stated that vaccination is being introduced among the natives of the Lower Congo by the doctors of the Belgian Expedition.

Phosphorus in Diabetes.—Dr. Balmanno Squire relates the history of a gentleman, sixty years of age, who was brought to him suffering from eczema. He also had diabetes. Phosphorus was ordered for the relief of the eczema, which it benefited very much, but at the same time it seemed to exert a most favorable influence upon the diabetes. The amount of urine passed in the twenty-four hours was greatly diminished, and the thirst, from which the patient had suffered greatly, caused very little annoyance.—*British Medical Journal*, November 30 1889.

Iodide of Ethyl in Bronchitis.—Dr. Robert Main has found iodide of ethyl in 10-minim doses, sprinkled on a handkerchief and then inhaled, very beneficial in cases of bronchitis complicated with Bright's disease, and fatty heart with feeble circulation (*British Medical Journal*, November 30, 1889). It is especially useful when the bronchial secretion is viscid and there are urgent symptoms of dyspnœa. About five minutes after the inhalation the patient coughs and expectorates freely, which relieves the distressing dyspnœa.

Madrid is blessed with one physician to every seven hundred of its inhabitants.

Medical Schools in Turkey.—A Hungarian journal gives the following particulars as to medical education in Turkey. In the whole Turkish Empire, including Egypt, there are five medical schools; two (one at Constantinople, the other at Cairo) which rejoice in the title of "Imperial," and three founded and kept up by missionaries, two at Beyrout and one at Aintabia. The Medical Faculty of Constantinople was established by Sultan Mahmud in 1833; at first the official language was French, but this is now gradually being replaced by Turkish. The curriculum extends over six years. Up to the present time fourteen hundred diplomas have been conferred by this Faculty. The Cairo school was established in 1827. The course of study there lasts six years and eight months. The average number of practitioners who yearly obtain their qualification from the Cairo Faculty is twenty. In the missionary schools the curriculum extends over four years, but they cannot give a legal license to practise; in order to obtain this candidates must pass an examination at Constantinople or Cairo. Foreign practitioners have to undergo a *vivâ voce* examination, the scope of which, however, is merely to discover whether the candidate is a genuine medical man or not. This examination is usually held in French, but if the candidate is ignorant of that language he may be examined in any other, with the help of an interpreter if necessary.—*Medical Recorder*.

Poisoning by Potatoes.—Dr. Cortail reports in the *Archives de Médecine militaire* a number of cases of poisoning by new potatoes. The most prominent symptoms were headache, dilatation of the pupil, colic, diarrhœa, sweating, feverishness, epigastric pain, vertigo, and sick stomach.

Ricord's Paste consists of pure sulphuric acid and powdered charcoal mixed together to form a thin paste.

Compulsory Notification of Disease.—Dr. Charles H. Bowen, of Washington, suggests the passage of an act in all the States giving to physicians a fee of two dollars for every certificate of birth, death, and contagious disease, and one of from ten to one hundred dollars for testimony at a coroner's inquest, or in any judicial proceeding.

Putting New Wine into Old Bottles.—Dr. Theodor Clemens, writing in the *Allgemeine medicinische Central-Zeitung*, proposes the injection of the freshly passed urine of a child into the bladder for the cure of chronic cystitis in aged persons. The bladder is first thoroughly washed out, and then filled with urine which has just been passed by a healthy child. He claims to have obtained excellent results with this novel therapeutic agent.

THE PHARMACOPŒIA OF THE UNITED STATES.

BY OSCAR OLDBERG,

PROFESSOR OF PHARMACY IN THE ILLINOIS COLLEGE OF PHARMACY, CHICAGO.

As there can be no therapeutics without materia medica and pharmacy, and as purity and uniform potency are necessary qualities in all medicines, every physician owes it to himself and to his art to do his share toward providing and maintaining proper and authoritative standards for the drugs and pharmaceutical preparations he employs.

Every civilized nation has its pharmacopœia. In all countries except the United States the national pharmacopœias are compiled, revised, and published by governmental authority; in all countries, the United States not excepted, have the national pharmacopœias the authority of law. The standards of purity and strength fixed by the United States Pharmacopœia have been repeatedly recognized in legislation and sustained by the courts. Were it necessary, we could readily demonstrate the absolute necessity of authoritative legal standards of this kind, and that the one code of such standards must be *the* National Pharmacopœia; but these propositions seem so self-evident as to require no demonstration.

But—do all the physicians of the United States, and all the pharmacists, fully appreciate the character and importance of their Pharmacopœia? Deplorable as it is, not one-third of them possess it! The case is far from hopeless, however, for a far greater proportion of the physicians and pharmacists own copies of the Pharmacopœia of the United States now than at any previous time in its whole history, and greater interest is manifested in the work.

The present Pharmacopœia of the United States is one of the best in the world; but one great blemish attaches to it, as well as to all other pharmacopœias. This blot upon it is so serious as to lower its dignity and detract from the respect and recognition which it ought to merit and receive. The next Pharmacopœial Convention, which is to convene at Washington on the 7th of May, 1890, ought to correct the evil, and if the matter is rightly understood there should be no difficulty about it.

The medical profession can do much to make the Pharmacopœia of this country an example worthy to be followed by all other countries, in the important direction which the writer proposes to point out in this appeal; and it is hoped that the physicians will take a sufficiently lively interest in the question to attend the Convention in as great numbers as the pharmacists.

In 1880, when the last National Pharmacopœial Convention was held, the medical colleges and societies were more strongly represented than ever before, thirty-two of these bodies having appointed sixty-two delegates, of whom forty-five were present, aside from the delegates sent by the Medical Departments of the Army, the Navy, and the Marine Hospital Service. But unless the medical societies and colleges generally take greater interest in the next Convention, they will be in the minority as decidedly as they have heretofore been in the majority. In the Convention of 1880 there were only eleven pharmaceutical bodies represented; but at that time only the colleges of pharmacy were entitled to representation, and nearly all of those then in existence were actually represented; while now there are about thirty colleges of pharmacy, and probably about fifty pharmaceutical societies, which are entitled to representation, and will undoubtedly be there through their delegates.

That the actual work of revision of the Pharmacopœia should be done chiefly by pharmacists is not only natural but necessary; but the medical profession also have their duty to perform, and it would be fatal to the character, value, and authority of the national code should it fail to receive active co-operation and full recognition by the medical colleges and societies.

The British Pharmacopœia is issued by the General Medical Council, although the details of the work are necessarily for the most part entrusted to pharmacists. The German Pharmacopœial Commission consisted of six clinical practitioners, six physicians, six pharmacologists, six chemists, six pharmacists, two army surgeons, and one army corps staff-apothecary. In other countries also the custody of the pharmacopœial interests is largely in the hands of the medical profession.

In 1879 an effort was made to take the Pharmacopœia of the United States out of the hands of the pharmacists entirely, and to place its publication and periodical revision in the exclusive charge of the American Medical Association; but that effort was fortunately unsuccessful, the Association declining to accept the charge.

Both physicians and pharmacists are equally and vitally interested in the Pharmacopœia, scientifically, professionally, and legally. But no past or present pharmacopœia, of this or any other country, can command that degree of respect and allegiance which should be freely accorded to such a code, because the true character and functions of a pharmacopœia have never yet been fully recognized and asserted. The object of this paper is to appeal to the medical and pharmaceutical professions of the United States to give to their future Pharmacopœia its true character.

The Pharmacopœia is looked upon as an index of authorized drugs and preparations, with formulas for the latter. And yet that is precisely what no pharmacopœia in this enlightened age can or should be, and until that blighting notion shall have given place to a more rational, consistent, and scientific understanding of the true scope and functions of the book it will not be able to command due respect on the part of enlightened physicians and pharmacists.

These statements will probably strike many readers as extravagant; but the writer is hopeful that a mere showing of the facts upon which they rest will prove sufficient to warrant them.

The blemishes which we will point out are such as result from the false idea which has been permitted to prevail regarding the nature of the Pharmacopœia, and will be at once swept away as soon as its true function shall be recognized and fixed.

One of the serious errors of which we have been guilty all along in the revisions of pharmacopœias is the inherited conceit that a Pharmacopœia is, or ought to be, an index of authorized medicines, in the sense that medicines *not* contained in the Pharmacopœia are understood to be not yet sufficiently tried, or not approved, and that age is not only an absolutely necessary qualification, but even the most important of all qualifications, for the admission of any remedy into the official codex. This ultra-conservative notion has not only kept out of the pharmacopœias many new and valuable remedies—which is cer-

tainly a disadvantage—but it has had the very bad effect to cause the retention in all of the pharmacopœias of a lot of obsolete, trashy, wholly absurd concoctions, which disfigure it and lower its character. No pharmacopœia is clean and respectable which is loaded down with compound therapeutic mixtures and other articles which have nothing to commend them except their antiquity and their reputation among the credulous or ignorant.

The recently revised issues are, of course, cleaner than their predecessors, but a great deal still remains to be done before the pharmacopœias are sufficiently purged.

The German Pharmacopœia contains a less number of questionable and superfluous preparations than any other, but it has 20 different kinds of ointments, 9 plasters, 5 mixtures, 5 liniments, 10 waters, 8 powders, 5 teas, 13 spirits, 19 syrups, 6 wines, and several compound tinctures; and among these preparations we find such things as the old "Four Thieves' Vinegar," Zittmann's Decoctions, Hoffmann's Stomach Elixir, Hoffmann's Balsam of Life, Elixir of Long Life, two kinds of Opodeldok, Carmelite Spirit, Stomach Bitters, Sydenham's Liquid Laudanum, Nervine Ointment, etc.

The British Pharmacopœia contains 12 different kinds of troches, 21 kinds of pills, 43 ointments, 14 plasters, 8 kinds of suppositories, 28 infusions, 13 decoctions, 10 mixtures, 16 liniments, 14 waters, 6 poultices, 8 confections, 5 enemas, 15 compound powders, 15 kinds of spirits, 6 inhalations, and 10 wines.

The French Pharmacopœia contains 20 kinds of troches, 23 kinds of pills, 29 ointments, 7 cerates, 14 plasters, 36 waters, 71 infusions, 7 decoctions, 89 syrups, 20 wines, 22 liniments, 21 juices, 3 chocolates, 5 lemonades, 11 potions, 11 baths, 6 fumigations, 6 kinds of cigarettes, and 1 beer!!! And among the official titles in that pharmacopœia are still found, in the year 1890, the following names: Vulnerary, laxative, purgative, sudorific, antiscorbutic, catheretic, escharotic, sedative, dentifrice, vesicatory, resolvent, carminative, diuretic, emollient, pectoral, fumigant, astringent, soothing, digestive, "ante-cibum," antipsoric, nervine, antispasmodic, sternutatory, and antiseptic. The French Pharmacopœia has a number of "alcoolates" with from 3 to 19 different ingredients, an "alcoolature" with 19 substances in it, mixed teas with from 4 to 20 constituents, a "pommade" with 8 ingredients; its compound syrup of rhubarb has 10 ingredients, the compound syrup of ipecac 9, and the compound syrup of erysimum 14, one of its vinegars has 14 ingredients, it contains four electuaries having from 10 to 15 ingredients, and one electuary composed of 58 drugs!!! Can such a pharmacopœia command respect?

The Pharmacopœia of the United States is not as richly supplied with ready-made prescriptions and absurd polypharmaca, but it is not free from them. It sets before us 16 kinds of troches, 15 kinds of pills, 26 ointments, 8 cerates, 17 plasters, 11 mixtures, 10 liniments, 14 waters, 34 syrups, 20 spirits, etc. Do we want all of these in the Pharmacopœia? If so, are there not a great many more pills and mixtures equally entitled to the distinction of being made official? Among the preparations of our Pharmacopœia we have Griffith's Mixture, Brown Mixture, Basham's Mixture, Dewee's Carminative, Compound Cathartic Pills, Plummer's Pills, Lady Webster's Dinner Pills, Tully's Powder, Compound Pectoral Powder, Strengthening Plaster, etc., each with from three to ten ingredients. The writer does not claim to be in any degree a judge in questions of therapeutics; but it does not require a therapist to question the propriety of putting such preparations in the Pharmacopœia, any more than it takes a classical scholar to know that the O'Flannigans did not inherit their family name from some Roman patrician.

The Pharmacopœia of the United States contains in all nine hundred and ninety-seven drugs and preparations. Of the many preparations, there are at least fifty which should be expunged in the next revision, namely: Black Drop, Elixir of Vitriol, Confection of Senna, Compound Decoction of Sarsaparilla, Compound Extract of Colocynth, Compound Fluid Extract of Sarsaparilla, Black Draught, Compound Liniment of Mustard, Griffith's Mixture, Basham's Mixture, Brown Cough Mixture, Dewee's Carminative, Neutralizing Mixture (Rhubarb and Soda), Oil of Wine, Aloe Pills, Pills of Aloes and Asafetida, Italian Pills (Aloes and Iron), Lady Webster's Dinner Pills, Rufus's Pills, Plummer's Pills, Asafetida Pills, Compound Cathartic Pills, Griffith's Pills, Blancard's Pills, Antihysteric Pills, Opium Pills, Phosphorus Pills, Compound Rhubarb Pills, James's Powder, Kurella's Pectoral Powder, Compound Jalap Powder, Tully's Powder, Gregory's Powder, Hoffman's Anodyne, Gin, Bay Rum, Cologne Water, Syrup of Lactophosphate of Calcium, Syrup of the Hypophosphites with Iron, Spiced Syrup of Rhubarb, Compound Syrup of Sarsaparilla, Coxe's Hive Syrup, Syrup of Senna, Elixir Proprietatis Paracelsi, Friars' Balsam, Paregoric, Sweet Tincture of Rhubarb, and Aromatic Wine.

I would not dare to suggest the expulsion from the Pharmacopœia of such sacred preparations as: Blue Mass, Blue Ointment, Seidlitz Powder, and several other kindred relics. Indeed, I am so fearful of being hypercritical that I have not even included in the list the Ammoniac Plaster with Mercury, Pitch Plaster with Spanish Flies, Confection of Rose, Infusion of Digitalis, Soap Liniment, Aromatic Spirit of Ammonia, and the Mucilage of Sassafras Pith, which I have no doubt are still cherished by so great a number as to be invincible. It is not even proposed to abolish from the Pharmacopœia such prescriptions as the official formulas for Ointment of Carbolic Acid, Decoction of Iceland Moss, Mixture of Asafetida, and Rhubarb Pills. Of course, it would be a consummation devoutly to be wished to get rid of all preparations which are wholly superfluous, never, or very rarely, prescribed by physicians, easily prescribed extemporaneously if ever wanted, unscientific, or useless because other and better preparations of the same drugs are in the Pharmacopœia or can be devised; but that is not now proposed.

It is only proposed to drop the particular forty-eight preparations named in this paper, and to define by resolution the character, scope, and functions of the Pharmacopœia in such a way as to prevent, if possible, the introduction into that book of any such compounds hereafter.

What would be the effect of dropping them? The only effect would be the purification of the Pharmacopœia. All who may wish to continue to use these preparations can do so to their heart's content, and with as great ease as ever before. There are hundreds of preparations which are in part prescribed by physicians, and in part employed as family medicines, for which there is a sufficient popular demand to render it desirable that their composition be fixed so as to be uniform for the whole country. A "National Formulary" has therefore been compiled by the American Pharmaceutical Association and the State Pharmaceutical Associations, jointly, which is a collection of formulas for all preparations commonly used or prescribed, but not contained in the Pharmacopœia. This National Formulary is already in the hands of a greater number of druggists than the number who have the Pharmacopœia; it is recognized as the standard for all the preparations it contains; it will be periodically carefully revised, and it is clearly the proper repository for all extemporaneous preparations requiring formulas for the sake of convenience, and for all compounds of such a character that their introduction or retention in the Pharmacopœia is doubtful. Any preparation dropped from the Pharmacopœia would, of course, be immediately taken up in the National Formulary, and the art of making Black Drop, Black Draught, and Dewee's Carminative would not be lost, but these valuable panaceas would continue to be made all over the country by precisely the same formulas, as certainly as if they were still adorning the pages of the Pharmacopœia.

But, someone will say, the pharmacopœias are now much better than they formerly were in this respect, and we will, no doubt, gradually get rid of the rubbish that is still left in them; while there is no danger that any more such preparations as those described will again be made official. To this the answer is that in the last revision of the Pharmacopœia of the United States there were for the first time introduced in it Basham's Mixture, Dewee's Carminative, Kurella's Cough Powder, Tully's Powder, and other similar mixtures. They were introduced then into the National Pharmacopœia because there was a demand for them, and it was not deemed improper to make them official preparations because it was believed to be the province of the Pharmacopœia to furnish formulas for almost anything and everything in the way of medicines for which there is an established demand, and the older the preparations the greater their right to a place in that book. The writer held the same views, and voted the same way, but he has since given the subject sufficient thought to be convinced that the Pharmacopœia should no longer be abused in that manner.

I will now endeavor to state my views as to what the Pharmacopœia should be, and what it should not be.

The Pharmacopœia should be a collection of authoritative titles, definitions, and descriptions of all simple drugs and preparations commonly employed by medical practitioners, and of all new drugs and preparations which, by their ascertained physiological effects and chemical constituents, give such promise of usefulness as to warrant their extended therapeutic trial, together with standards of quality, purity, and strength; and, finally, the best methods of preparation of such simple and rational pharmaceutical preparations as may be necessary for the convenient and effective employment of the respective drugs enumerated in the book. It should be *the* authority to which we can turn to find the recognized technical name of any medicinal substance of importance; the correct and exact definition of the title belonging to it; a description sufficient to enable us by its aid to recognize that substance; tests by which we may determine the identity and purity of such medicinal substances as can be so identified; standards of strength for all medicines which can and should be made of definite, uniform strength; and scientific working formulas for all the requisite preparations of each drug according to its uses.

The Pharmacopœia should *not* contain any medicine simply because of its antiquity, nor exclude another because it is new; it should not contain any crude drug, such as a part of a plant which cannot be advantageously employed in its crude condition, unless working formulas are at the same time given for such preparations of it as render its advantageous use possible; it should not contain any ready-made prescriptions, nor any polypharmacal preparations or mixtures of several distinct, active, therapeutic agents.

The Pharmacopœia already contains, probably, nearly all drugs and preparations that would consistently find place in it in accordance with the views herein set forth. But even if as many as a hundred new drugs and preparations should be introduced in consequence of the revised ideas of the scope of the work, that would only be a decided improvement.

Our present Pharmacopœia contains not less than thirty-two roots, barks, and other crude drugs, which certainly cannot be prescribed or used in their crude state, as found in the drug market; if these drugs are worthy of a place in the Pharmacopœia, then the Pharmacopœia should, of course, also provide formulas for making fluid extracts, extracts, tinctures, or other rational pharmaceutical preparations of them. If Salol should be introduced into the National Pharmacopœia, no preparation of it would have to be introduced at the same time, for Salol is prescribed in substance; but what good would it do to put Quebracho Bark, or Coto Bark, or Strophanthus, or any other plant drug, into that book without furnishing at the same time official formulas for fluid extracts of them?

It has been the fashion in the past to strenuously oppose the introduction of any new drug, chemical, or preparation into the Pharmacopœia, because the general understanding was, that whenever any substance had a place in that work, that fact alone constituted strong evidence that it had received the general approval of the medical profession; and, *per contra*, whenever any substance failed to be voted into the Pharmacopœia, it was assumed that its use was disapproved. But it should in no wise be the function of the Pharmacopœia to approve or disapprove, affirm or deny, the use or value of any medicine. The writer believes, on the contrary, that whenever any drug has been carefully examined as to its physiological action and chemical constituents, and these examinations should strongly indicate marked therapeutic potency, that drug should unquestionably have a place in the Pharmacopœia, even if it had not been tried at all in medical practice; because, since it is evident that it will be so tried, its trial should be made under the most favorable circumstances possible—it should be rendered convenient to verify the identity of that drug, to pass intelligent judgment upon its quality, and to obtain uniform and properly made preparations of it. The fact that a new and untried drug, or a newly introduced and insufficiently tried chemical, has been placed in the Pharmacopœia, should have no significance whatever as to the real value of the substance; it should simply be understood that anyone who wants to try it or use it, can find out in the Pharmacopœia what it is, how it may be recognized, and what forms of administration or application are provided.

If these views of the true character and functions of the Pharmacopœia should be shared by a majority of the delegates to the next National Pharmacopœial Convention, and acted upon, then the Pharmacopœia of the United States would soon be made the cleanest, the most dignified, scientific, and consistent pharmacopœia in the world, and would command universal respect. And yet, so far as articles dismissed and admitted are concerned, the changes would be comparatively insignificant, and could certainly not cause any inconvenience. The size of the Pharmacopœia would remain about the same; but as to its scope and functions, it would at once assume a leading position. Such, at least, are the convictions of the writer, who bespeaks for his propositions the critical and candid judgment of the physicians and pharmacists of the United States.

MINOR LACERATIONS OF THE CERVIX.

By CHARLES H. BUSHONG, M.D.,

ASSISTANT GYNECOLOGIST AT DEMILT DISPENSARY, ETC., NEW YORK.

The importance of lacerations of the cervix uteri does not entirely depend upon their size. Many of them are either entirely overlooked, or regarded as of no importance. The object of this paper is to set forth their claims for treatment. Many women who have had one or more children complain of symptoms the cause of which seems obscure. They are about as follows: The first pregnancy goes to term without accident; delivery is normal, frequently "easy," and apparently without injury to the canal. This is followed in a few years by one or more pregnancies terminating in abortion, usually before the fourth month. These may be the only symptoms; but there is often leucorrhœa, and an increased amount of menstrual blood—unless there is anæmia, in which case the menstrual discharge is scanty or absent. The patient often has "nervous" symptoms, is fretful, and inclined to worry, and frequently loses flesh. A case with such a history may go a long time before consulting a physician, and then a correct diagnosis is frequently not made. An examination will reveal only a small laceration of the cervix, seemingly too small to cause any symptoms. Closer inspection will reveal some cicatricial tissue around the

tear, and a uterus slightly larger than normal. General treatment fails to ameliorate this condition, while treatment of the cervix produces excellent results. The following histories, taken from my case-book, belong to this class:

Case I.—Mrs. H——, aged twenty-six, had one child about five years ago. Two years ago she had an abortion at the fourth month. I first saw her at this time. The only peculiarity about this delivery was a prolapsed cord. A slight laceration of the cervix was then found, for which treatment was advised but neglected.

She was next seen one year later, when she was much run down, had lost appetite and flesh, and had had amenorrhœa for six weeks. As there is pulmonary phthisis in her immediate family, a careful examination of the chest was made, but failed to give any evidence of tubercular disease. Then examination for possible pregnancy was advised, but, at her request, was not made until one month later. There had been no morning sickness at this time, and the mammæ were negative. Medicinal treatment for increase of appetite and strength was ordered.

About the middle of May the pelvis was examined. There was much leucorrhœa, the cervix was soft and lacerated, with a small area of hard tissue around the tear; the uterus was large, about the size of a three-months' pregnancy. The chief complaint at this time was that the leucorrhœa "weakened her," and that she had suffered from nausea and vomiting, principally in the morning, for one week. Her general condition was somewhat improved. The tonics were continued, and pure liquor Monsel was applied to the cervix, followed by a tampon saturated with glycerine, to be worn about twelve hours. These applications were made once a week for the purpose of removing the hard cicatricial tissue around the tear. Her condition at once improved. The morning sickness decreased from the beginning of this treatment, and soon ceased to give any trouble. The leucorrhœa diminished, and strength and appetite increased. This treatment was continued two months only, when her symptoms had all disappeared, and she went on "to term" without further incident. When examined two days before her confinement, the cervix was found entirely free from cicatricial hardening, and with no perceptible break in its continuity. She was delivered October 31st, labor lasting about two and a half hours. The child was a medium-sized boy.

December 10th, six weeks after confinement. She feels well in every way, appetite good, and her only complaint is of weakness and of some pain in the pelvis when on her feet. Examination shows no cicatricial hardening in the cervix. A small depression is the only evidence of the old tear. A small laceration is found on the opposite side of the outer lip of the cervix. This is all the injury she received, and the applications of iron will soon heal it.

Case II.—Mrs. McK——, aged thirty-five, had one child nine years ago, and has had only one pregnancy since, when she miscarried at two and a half months. When first seen, at Demilt Dispensary, the cervix was large, and there was a small laceration, with an area of hard tissue around it. The uterus was slightly enlarged and anteflexed, and the inner os was constricted.

Sounds were passed gradually dilating the constricted internal os, and the cervix was treated with liquor Monsel and tampons. In about three months she was both surprised and gratified to find herself pregnant. She had ceased to come for about six weeks, and came back complaining of morning sickness, and that she had not menstruated in more than a month, when pregnancy was found to be the cause. A few applications of iron and tampons were made, and the morning sickness soon ceased. The treatment was continued, somewhat irregularly, until the fifth month. She was delivered at term of a well-developed boy, after a labor of about four hours. The old cicatricial tissue had all disappeared before her accouchement, and the cervix received little injury at that time.

Many histories like the above are in my case-books. These will suffice to show the benefit from local treatment.

The next case was never seen until her labor had begun. It is not an extreme one, as the consequences of neglect are often more serious.

Case III.—Mrs. S——, aged thirty-five; first seen August 16, 1889, in her seventh labor. Examination showed the os dilated only enough to admit one finger. A very decided feeling around the cervix, like a tense drawing string, was noticed. This constriction was a cicatricial band extending each way around the cervix from a small laceration. It was hard and inelastic. She was first seen at 5 P.M., and was in labor, with very strong and frequent pains almost continuously, until midnight of the next day. By this time the os was about the size of a half-dollar. The drawing-string feeling was still very pronounced. She was weak and worn out, but objected to forceps, so a flexible catheter, well sterilized, was carefully introduced and passed to the fundus uteri, only the end protruding through the os into the vagina.

This produced more intense pains, which lasted for about an hour, when all pains began to die out and the weakness became pronounced. She now asked for assistance. The forceps were introduced with some difficulty, and a male child, not larger than usual, was delivered with their aid in about half an hour. The cervix was much torn. The scar tissue prevented a dilatation large enough to allow the head to pass. The cervix had to be torn, and the uterine muscle was not able to do this with thirty hours of hard labor. If the old laceration had been deeper, it would have interfered less with the passage of the head.

My experience, in cases similar to the above, has shown that appropriate treatment of the cervix will soften it and renew its elasticity sufficiently to allow a normal delivery to occur without material injury. This result is possible even when treatment is begun after gestation has advanced several months.

The following case is introduced to show the beneficial effect of appropriate treatment on the *nervous* symptoms that frequently accompany these minor lacerations of the cervix:

Case IV.—Mrs. S——, aged thirty-six, a widow, had one child six years ago, which was her only pregnancy. For the past eight months she has noticed a loss of a greater amount of blood than usual at each menstrual epoch, and has become weak, easily tired, very nervous, has lost appetite, and has much dysmenorrhœa and leucorrhœa.

Treatment, for a month, was directed to the alimentary canal and the use of tonics, before a pelvic examination was consented to. She continued to get worse and the menorrhagia became very distressing. She was irritable and despondent, a change from her normal happy disposition. A vaginal examination was urged and now allowed. The uterus was found anteflexed and slightly enlarged, the cervix was very large and contained nodules of hard tissue, and its contour was incomplete at one place. She was given a tonic laxative and had iron applied to the cervix, and packing of the vagina with cotton-glycerine tampons. These applications were made twice a week during the three weeks between each menstrual period. Now, after two months' treatment, she is stronger, has less nervous symptoms, no dysmenorrhœa, loses a normal amount of blood, has little leucorrhœa, and, as she says, "don't worry any more." The cervix is much smaller and softer, and the uterus is of normal depth.

I could add several similar cases, but these are sufficiently typical to illustrate the need of a more careful watch for these apparently insignificant breaks of the cervical continuity, and their need of careful treatment. The alleviation of the nervous symptoms in Case IV. is especially to be noted. The inclination to worry and be fretted by trifles is frequently a prominent symptom. The relief from vomiting, as shown in Cases I. and II., is also worthy of notice, as this symptom is often very difficult

to control by drugs. Counter-irritation is a safer method than the stretching of the cervix, that has been frequently recommended for it. It is certainly worthy a trial; inexperience or want of skill can do little injury with it.

The iron lessens the cervical tension and the irritability of the reflex nervous centres, while the tampon supports, for a time, the enlarging uterus, and gives the ligament rest, and the glycerine lessens the peri-uterine congestion.

It is also worthy of note that each of these two cases (I. and II.) miscarried with the first pregnancy after that which had caused the injury of the cervix; but when properly treated, each was carried in safety past the time of previous abortion, usually so dangerous, and enabled to complete her period of gestation. While a deep laceration makes the entrance to the uterus more patulous, these slight injuries do not, and the unaided efforts at their repair destroy the elasticity of the cervix. The treatment above outlined removes this hard tissue and restores its normal flexibility, the absence of which is the main source of danger.

I may add, in closing, that so-called solvents will not always be found sufficient to remove these indurations and effect a closure of the torn cervix. In such cases it is necessary to dig out the hard tissue and sew up the laceration; but they are without the scope of the present paper.

355 West Fourteenth Street.

INCOMPLETE LUXATIONS OF THE METATARSO-PHALANGEAL ARTICULATIONS.

By CHARLES E. WOODRUFF, M.D.,

ASSISTANT SURGEON, UNITED STATES ARMY.

There are several painful affections of the metatarso-phalangeal articulations due to incomplete luxations of the bones. Dr. C. L. Dana has shown (The Medical Record, July 25, 1885) that some of these cases have been described, as early as 1833, in France by Velpeau, subsequently by various other French writers, and in this country by Dr. S. Weir Mitchell in 1872, and Dr. Morton, of Philadelphia, in 1876. The subject seems to have been taken up as a new one, in an article by Dr. Auguste Pollosson, of Lyons, referred to by the London *Lancet* (March 2, 1889), in which one form of luxation is called "metatarsalgia." Much correspondence followed in the *Lancet* for March 16th, and April 6th and 13th, though it appears that attention to these painful affections is not new in England; for reference is made (*Lancet*, April 6th) to the treatment pursued in these cases by Dr. Reeves ten years before.

These luxations, though seemingly trivial, cause much distress and inconvenience, and at times the pain becomes so severe as to be almost unbearable, as I can testify from personal experience. A careful perusal of the recorded cases at my disposal shows that they are not similar by any means, and none of them correspond to the three other cases I have seen. The cases lately referred to in the *Lancet*, and called "metatarsalgia," are probably exactly the same as the more severe cases of "policeman's disease" and "tarsalgia" described by Velpeau and others, and Dr. Mitchell's cases, referred to by Dr. Dana, and probably also some of Dr. Morton's cases. In all these, from prolonged standing or walking, injuries or falls on the feet, and in people having relaxed ligaments, the metatarsal arch gives way from stretching of the transverse ligaments, allowing the third metatarsal bone to drop to the level of the others. It occurs therefore among policemen, dentists, shopkeepers, and others who are on their feet during much of the day. The disturbance of the positions of the parts causes pressure on the nerves, particularly the small digital branches of the plantar nerves, running along the sides of the heads of the metatarsal bones. This explanation, given by various writers, is undoubtedly the true one, from the relief afforded by preserving the arch of the metatarsus transversely, by a pad or some inflexible material used as a false sole to the shoe and fashioned to fit the arch. Exercises, such as standing on tiptoe, which strengthen the transverse ligaments, have also cured a case (Dr. Edward Roughton: *Lancet*, March 16th).

My own cases are entirely different, occurring in people not accustomed to much standing or walking, not having relaxed ligaments nor flattened metatarsal arches, having no history of injuries, and not benefited, but, on the contrary, made worse, by exercises like standing on tiptoe. They are so easily relieved that they deserve mention. They are all due to a very slight displacement upward of the proximal end of the first phalanx of the third or fourth toe, generally the third, and caused by forced dorsal extension of the toes on the metatarsus. In some cases the luxation is brought on by merely assuming a partially kneeling attitude, with the sole of one foot upon the floor, and the other supported on the extended toes, the person almost sitting on the latter foot, thereby resting his whole weight on the extended toes. In whatever manner forced extension is made, the phalanx slides up on the head of

Fig. 1.

its metatarsal bone, as seen in Fig. 1, and when flexion takes place it does not slide back but rotates until it assumes a position as seen in Fig. 2.

Fig. 2.

The first phalanx of the second, third, or fourth toe, having no muscular attachments except the feeble interossei, has no aid from muscular contraction to help keep it in position. I do not know why the middle toe should be the one nearly always affected, unless it is due to the fact that when the weight of the body is thrown on the toes, dorsally extended, the third metatarsal, being the key of the arch, is brought near the floor, and causes the corresponding toe to be more forcibly flexed and receive more of the weight than the others. A slight flattening or hollowing out of the end of the metatarsal would materially aid in preventing the return of the phalanx. Habit undoubtedly is a great factor in perpetuating the trouble, and after a few attacks the dislocation is produced by very trifling motions of the toes.

It is this very slight degree of luxation which I have often made out in my own case, and which is the cause of all the agonizing pain which soon appears. The pain is of a burning character, and located in and under the joint. Should the luxation remain unreduced, the burning becomes steadily more and more severe, and finally involves the whole anterior part of the foot. Yet the pain will cease as if by magic when the luxation is reduced.

Extension and counter-extension applied with force enough to produce the familiar "snap," or "crack," will invariably, in my own case, reduce the luxation and stop the pain; and in the other cases in which I have advised it, the shoe can be worn at once and with comfort. Grasping the foot in the hand, or pressing it between the hands, on sole and dorsum, will ease the pain; but the bone is not reduced as by extension and counter-extension, and the shoe cannot be worn comfortably until the toe works itself back into place, which may be hours or days.

Of course, the only prophylactic is to be careful to prevent any forced extension of the toes of the affected foot. A great aid to this is to wear shoes with soles having but little flexibility. Three of my cases were never troubled when they wore thick soled-shoes, the fourth did not try it. All positions, attitudes, or movements which cause forced dorsal extension of the toes must be carefully avoided.

The whole affection appears at first sight to be so trivial as to merit but little or no attention, but in the cases I have seen it has at times been a very serious matter to the patient. In one case the gentleman once caused the luxation just before seating himself at a banquet, and it is needless to remark that he found no pleasure at all in his joyous surroundings. In another case, a lady imagined that the pain was caused by forcible flexion of the toes, and tried repeatedly to counteract the trouble by forced dorsal extension, only to cause more pain. By keeping the toes in line with her foot, preventing either flexion or extension, she had no return of her trouble, until she neglected the precautions.

The cases are so nearly alike that a description of them is unnecessary.

Besides these two classes of luxation there are other cases, reported by Dr. Morton, which appear to be entirely different, being in the fourth metatarso-phalangeal joint, and probably due to subluxations of the metatarsals upon one another, and caused by blows upon the instep, severe falls on the feet, and other accidents. Some of his published cases were cured only by excision of the painful joint.

There is really no need for a name for these pains, any more than there is need for a name for the pain due to dislocation of the shoulder or of the hip. If we call it "metatarsalgia," we should invent a name for the pain in each form of luxation, for we are just as liable to have "metatarsalgia" in the hand as in the foot, which, as mentioned by a correspondent of the *Lancet* (March 16th), is about equivalent to having "toothache in the toe."

Since the above has been written, I have learned of still another form of subluxation, but this time in the *tarsal joints*. The patient, a lady, states that by certain motions of the foot, combined with flexion of the ankle-joint, there would occur a severe burning pain located in the tarsus at its inner side. The pain would become worse, and there was a sensation as though "a red-hot iron had been thrust into my foot," to use her own words. It was unbearable pain, and she found by experiment that she could stop it by manipulating the foot and stamping on the ground. The pain would sometimes occur while she was in bed asleep, from her unconscious movements. She finally learned by experience what movements caused the pain. By the exercise of great care she avoided the movements, until she was able to do so involuntarily. For several years she has been free from her trouble. This case is undoubtedly one of subluxation of one of the tarsal bones, probably the scaphoid. The pain, its mode of occurrence, and the mode of obtaining relief, are so similar to the cases described above that the case becomes of interest when considered with the others.

Perhaps many other cases of obscure and burning pains in the foot may be explained on the theory of subluxations of some of the many bones forming the complex articulations of this highly specialized organ. Indeed, it is not unlikely that the classical pain which many people in their youthful days have suffered, to gratify the vanity of observing the vast proportions of their feet compressed into smaller volume, may be a pain differing in no respects in origin from the cases already considered, the severe compression of the foot having caused slight displacements which are spontaneously reduced upon removal of the offending boot.

Pneumonia is still very prevalent in this city, and has a marked mortality.

THE ENFORCEMENT OF THE LAW FOR MUNICIPAL LODGING-HOUSES IN NEW YORK CITY.[1]

By HENRY E. CRAMPTON, M.D.,
NEW YORK.

The law whose enforcement we advocate to-night was passed June 2, 1886.

It authorizes the Commissioners of Charities and Correction to hire or purchase the necessary buildings for male night-lodgers, specifies the manner in which the funds for their maintenance shall be obtained from the city treasury, contains the essential clauses concerning the compulsory bath and work, and gives all needed powers.

Repeated efforts have been made to induce the Commissioners to move in this matter, but without success.

This is pre-eminently a sanitary question, and as such comes before us this evening.

The law is similar to the one in force in Boston, where it has worked well for nine years. There an applicant for a night's lodging receives at any police station a card of admission to a Wayfarer's Lodge. Here he receives a warm bath and a comfortable bed, and in the morning, after sawing a certain amount of wood or doing what other work may be required of him, has a hearty breakfast and leaves the lodge, equipped, physically at least, for the weary tramp for employment, or for his distant home.

Statistics show that this system has worked well in Philadelphia, Baltimore, Indianapolis, and Washington.

In New York City we treat the men and women who are too poor to pay for even the cheapest night's lodging very differently.

These men and women gather about our station-houses as night comes on; if it is stormy they come early.

You may see them any night lurking about in alleys or door-ways, or quarrelling for places in the line until six o'clock, when they are admitted, and after their name, age, and nativity are registered they are directed to the sleeping-room. This is a bare, stone-floored and brick-walled apartment, usually over the prison cells.

Here they range themselves, in their rags and vermin, upon narrow boards, raised about a foot from the floor by an iron frame. The women have a separate room similarly furnished. When these are filled, further applicants are turned away. A large stove with a generous fire supplies warmth, but assists in devitalizing the air; it permits, however, the use of the scanty clothing for a pillow.

The bacteria that swarm in the air, let us say at midnight, would delight the most confirmed bacteriologist. The foul odor is indescribable. In the morning early all are turned into the streets, as the hose must be freely used to prepare the chambers for the evening guests. The number of lodgings of this sort given in 1887 was 128,635. In 1888 the number had increased by 22,000. The total was 150,812. About forty-four per cent. were women.

It is interesting to note here that as a profession we have been true to ourselves in protesting against this vile system.

In 1867 the Board of Police Surgeons presented a report to the Department, from which I read the following extract:

"The Board of Surgeons is of the opinion that it would be recreant to its duty did it not strenuously urge upon the Board of Police the propriety, the economy, nay the absolute necessity, of discontinuing the practice of using station-houses as lodging-houses for vagrants. The practice is fraught with numerous evils; the huddling together like cattle of a large number of drunken, dirty, and ofttimes diseased wretches, contaminates the air breathed by the patrolmen in the same building. It engenders typhoid and other idio-miasmatic diseases, and is a prolific and traceable source of sickness among the officers and men.

[1] Read before the Section on Public Health, New York Academy of Medicine, January 3, 1890.

Besides this, the passing in and out of these lodgers frequently prevents the men from obtaining the necessary sleep, without which it is impossible that they should well and efficiently perform the duties required of them while on post. Some systematic, radical, and comprehensive change in this matter is urgently needed, such as the erection of lodging-houses for vagrants entirely disconnected from the station-houses.

"Whether the charitable providing of lodgings for the homeless and destitute be any portion of the duty of the Board of Police, and if so, what propriety there is in making it part of its duty, and whether this subject does not more naturally and more properly devolve upon the Department of Public Charities, are questions, though interesting in themselves, yet are not perhaps strictly within the scope of a medical report. It is, however, eminently proper, as a medical and sanitary question, to show that, to whichever department this matter more rightfully and properly belongs, lodging for vagrants should never be allowed in any portion of a station-house, for the reasons above stated."

Attention was first drawn to the formation of the Night Refuge Association in 1877, mainly through the efforts of the State Charities Aid Association, and to the repeated and combined efforts of various charitable associations, which finally resulted in the adoption by the legislature of the Act in question.

Secondly, this question is one which concerns the health of our police force.

In the annual report of the department for 1888, we find reported 311 cases of fever, nearly one-half of which are classed as malarial, and 334 cases of diarrhœal affections, including dysentery; 164 besides are set down under gastric derangement. It is certainly impossible to say how many of these and other cases of illness were caused by contact or proximity of sleeping apartments to those occupied by the night-lodgers, but that the presence of these sources of zymotic contagion is an important factor I have not the slightest doubt. We require of the police protection from the vicious and degraded, but we ought not to ask them to sleep with them, if we can help it. In some of the station-houses the sleeping-rooms of the policemen are over or near the night-lodgers' shelter.

We close with a summary of the reasons why the Act should be enforced.

1st. As a sanitary measure. "The health of our citizens, especially the police force, is endangered by a continuance of the present system."

2d. It is feasible. The success of a similar law in other cities is proof.

3d. It is humane. Our present method is inhuman and demoralizing.

4th. It is an economic measure. The compulsory bath and work will deter the lazy from applying, and assist in ridding our city of tramps. This result has been obtained elsewhere.

5th. It is necessary, as shown by the increase in the number of lodgings given—in 1887, 128,635; in 1888, 150,812.

NOTE.—The paper was discussed by Drs. R. H. Derby and Cyrus Edson, and (by invitation) Rev. Drs. W. R. Huntington and F. H. Warling, and Messrs. I. A. McKim and H. B. Turner, of the State Charities Aid Association, all of whom favored the enforcement of the Act.

Electro-therapeutic Quackery.—The manufacture and sale of electric belts, brushes, shoes, pads, etc., has reached such proportions in England that an effort is being made, in the interest of an ignorant and deluded public, to restrict, if it is impossible to repress, the traffic in such fraudulent appliances. A man who sold an "electropathic belt," which was warranted to cure sciatica, lumbago, Bright's disease, and a host of other ailments, has recently been arrested and fined for obtaining money under false pretences.

A CASE OF RECURRING PHLEBITIS.[1]

By A. A. SMITH, M.D.,
NEW YORK.

PHLEBITIS is not an affection of frequent occurrence. When it does occur, it is usually not difficult to discover a cause. Although in some cases it is described as of idiopathic origin, strictly speaking, one can say of such cases probably the cause has not been discovered. I have designated the case whose history I will read as recurring phlebitis. The patient has had four attacks, and in none of the attacks has it been possible to discover a satisfactory cause. Certainly none of the ordinarily recognized causes was discovered.

The patient, an Englishman, was engaged in business in London and New York. While returning to London from New York, on the steamer, within two days of Liverpool, he was seized, while walking on deck, with a severe chill accompanied by decided pain in the right leg. The pain was on the inner surface, extending from a point mid-way from the groin to the knee, over the track of the saphenous vein. The next morning there was swelling of the leg and foot and a feeling of stiffness and considerable pain in the leg above the knee. Every effort at walking was attended by pain enough to cause him to keep quiet. On the arrival of the steamer he went at once to London, consulted his physician, who pronounced it phlebitis and advised the usual treatment—rest, elevation of the leg, and warmth, etc. This was in October, 1879. He recovered from this attack in three weeks and resumed his business. On Christmas Day he was seized at the dinner-table with pain in the left leg, in about the same situation and with the same characteristics, except that it was more severe, and the leg began to swell within an hour. The following day it was swollen to twice its normal size. He was again treated in the usual way. In about three weeks all acute symptoms had disappeared. The swelling in the leg subsided somewhat, but, as is usual in such cases, it has never resumed its natural size. The first day he began to move about after the second attack he developed a pneumonia, which was probably due to a thrombosis. He was very ill for six weeks, but gradually recovered from it, and by June, 1880, had recovered his usual health, except the swelling in the left leg, and a moderate degree of tenderness over the course of the saphenous vein above the knee.

I saw him first in October, 1885, in this city. He then was suffering from an attack of acute phlebitis affecting the long saphenous on the left side, both above and below the knee. The attack was ushered in by a mild chill, and occurred after a period of three days of great mental anxiety and physical exertion in connection with his business. He was at that time forty-six years old and had never had a day's illness up to the time of his first attack. In fact, he considered himself a man of unusual physical vigor up to that time. He had always been a rather generous liver, both as to eating and drinking. He had for twenty years been an inveterate smoker. His attack yielded in a short time under the treatment ordinarily pursued. As this was the third attack, I was much interested in discovering, if possible, the etiology. He had been, up to his first attack, a man of unusual physical vigor, had never had syphilis, nor, by his own testimony, gout. He certainly had had no disease causing depression of vitality and had not received an injury. His urine showed only a few urates. Just after this attack he had pain and swelling in his tendo Achillis and its attachment, which yielded quite readily to White's anti-gout pill and iodide of potassium.

He returned to England a few weeks later. I did not see him again until September this year. He had remained well most of the time. On two or three occasions he thought he was threatened with an attack of phlebitis. On such occasions he would take the anti-gout pills and the iodide for a few days. He thinks this warded off

[1] Read before the Practitioners' Society, November, 1889.

the attacks. At all events he has had no attack until the one for which I visited him in September. He had developed the attack after unusual mental exertion and exposure on a sleeping-car. It came on, as two previous attacks had done, with a slight chill. This time it affected first the saphenous below the knee, gradually extending up above the knee, the portion above the knee becoming affected after it had partially subsided below. It affected the superficial epigastric vein in the wall of the abdomen a few inches above the groin. Since recovery from the acute symptoms of this last attack I have kept him steadily taking iodide, and about once a week an anti-gout pill. In view of the fact of the urates being abundant in his urine during the most of the time of the attack, I have endeavored to regulate his diet too. He says (in the early part of November) he has not been so free from stiffness and pain in his left leg in years as he now is.

The case presents some points of interest: The frequent recurrence, the lack of an easily recognized cause, the first attack occurring in a man of excellent physical vigor; no injury, no disease in tissues about the veins, no blood-poisoning. In most cases of gouty phlebitis it has occurred in cases in which the manifestations of gout were unmistakable. Can this case be included among the cases of so-called gouty phlebitis?

ON THE LEGITIMACY OF THE EXTENSIVE INTRANASAL SURGERY OF THE PRESENT DAY.

By J. M. W. KITCHEN, M.D.,
NEW YORK.

Intranasal therapeutics has experienced a fashionable change during the past few years. The treatment of chronic rhinitis by means of medicated sprays has been largely abandoned as a curative measure, and has even been extensively denounced as being of no benefit to the patient. In this instance the reaction has gone to an unjust extreme, for a great deal of good in the way of alleviation, and even of cure in exceptional cases, can be accomplished by a skilful use of very simple remedies in the form of sprays. But surgical procedures offer such prominent advantages, in producing quick and easily appreciable results, that the specialists have adopted the cautery, saw, drill, etc., with enthusiasm. Opinions differ widely as to the efficacy of this style of treatment. There is a wide difference between the views of the enthusiastic specialist who holds that nasal catarrh is caused by stenosis and can be cured by operation, and those of the pessimistic general practitioner who considers the malady a totally incurable one. The truth lies between these extremes. It is presumed that the advertising proprietors or the sure catarrh-cures still find enough patronage to keep the wolf from their doors, and certain it is that the hay-fever cases flock in crowds each year to exempt regions; yet there are hundreds of practitioners whose time is not by any means fully occupied, who stand ready to attempt cure by operation for a reasonable consideration. It would seem that this state of affairs indicates scepticism somewhere. I am free to admit that there is a reasonable basis for this distrust. Having had a fair opportunity, through practice and observation of the results by a reasonable lapse of time, to come to a judgment as to the merits of this mode of treatment, I herewith submit my conclusions on the subject.

There are a few cases of intranasal catarrh that can be radically cured by intranasal operation. These are cases in which great abnormalities of structure are undoubtedly prominent, and may be the only important cause of the trouble; but these cases represent a small section of the great mass of sufferers. It is true that, other things being equal, the individual who has a perfectly straight septum, and intranasal lumen of an approximately correct calibre, will be less liable to nasal catarrh than persons less favored; but, as a matter of fact, no person is so favored, and slight or even moderate deviations from the normal have only a small causative effect. The conditions at work in causing catarrhal affections in the nose are widespread and numerous, and in large measure are beyond the control of either the doctor or the patient. I do not remember to have operated on any nose but what I have accomplished more good than harm; but I have operated on more cases in the belief that I was giving curative treatment than I expect to operate on in the future holding that theory. Operations in the nose are not an unmixed blessing, especially those on the septum. The intranasal cicatricial dry patch is a decided nuisance, and even in cases of marked malformation it is sometimes a nice question to decide which is the greater evil, the disease or the result of the treatment. Almost all the good results of operation in the nose are in the line of alleviation, and any claims of an extensive nature for curative effect will in the very near future, in my opinion, indicate ignorance or worse in the practitioner. While such claims would not be legitimate, there is still quite a large field for the legitimate use of intranasal surgery in the alleviative treatment of nasal affections. It is a comfortable and healthful thing for an individual to have free nasal respiration and complete nasal drainage. There are certain effects of disease which, if not removed or corrected, will surely lead to greater evils. A certain amount of cicatricial tissue in many an individual's nasal cavities, if judiciously created, would prove a blessing to those so endowed. The cicatrices mechanically bind down the tissues, preventing nasal occlusion by their engorgement; destroy some of the too active nerve-terminals, and by interruption of the blood-current reduce the nervous irritability of neighboring parts. All this and more is good, legitimate surgery, and there are really no great grounds for denouncing the intranasal surgery of the day. Of course, there may be cases in which more harm has been done to the patient than good; but the reverse I believe has usually been the case. The only objection of importance that can be justly urged is that in this instance practice has forerun theory. The theory has been largely wrong; but the practice has been reasonably good. If there has been a fault, it has been born of ignorance. It may be of interest to some coming rhinologist to state that, while the field for *philanthropic* intra-nasal surgery is immense, the number of persons is very limited who will submit to operative procedures and then pay in hard cash for the infliction. Advising an operation in a charity patient inspires immediate confidence. The same advice to a possible pay patient in most cases calls out an ocular expression that says almost as plain as words, "Do I look so green a bird as all that?" Further than that, there are relatively fewer cases to be found among the financially well-to-do classes, who enjoy better hygiene and advantages of all kinds. In my opinion, the persons who will in the future be the most successful in *curing* intranasal affections, will be hygienic teachers, and the promoters of sanitaria in locations favored with superior climatic and other advantages.

Treatment of Diphtheria.—Dr. H. L. Manchester, of Pawlet, Vt., writes that he has been accustomed for some time to make use of the vapor of bromine in the treatment of diphtheria. His method is to put some solution of bromine in a shallow dish on a high shelf, since the vapor is heavy, and thus keep it constantly in the sick-room. Since employing this he has had much better success with his cases of diphtheria than he had before. He also brushes the throat with a soft camel's-hair brush dipped in tincture of the chloride of iron, and gives tincture of digitalis internally. Phenacetin and antifebrin are the agents which he prefers for reducing fever and quieting restlessness. Dr. Manchester has never seen any reference to the use of bromine as a disinfectant in the treatment of diphtheria, and if it does the work that he thinks it does it deserves, he says, to be more widely known.

Progress of Medical Science.

The Blood in Phthisis and Cancer.—Dr. G. Neubert has examined the blood in twenty-four cases of phthisis at various stages, and found that in nine the number of corpuscles was normal, in three it was above, and in twelve more or less below the average (*The Lancet*). On the whole, there was an average diminution of about eight per cent. The increase noted in three cases might perhaps he attributed to profuse night-sweats. The hæmoglobin showed a reduction to seventy-three per cent. in the females and eighty-five per cent. in the males. There was no notable change in the number of leucocytes, but it was observed that multi-enucleated forms predominated. In five cases of cancer of the œsophagus and four of cancer of the stomach there was an invariable diminution in the number of red corpuscles, and also notably of hæmoglobin. It is inferred that the hæmoglobin, being the more "sensitive" element of red corpuscles, is more profoundly affected in cachexia than the stroma of the corpuscles. A distinction was made between the anæmic and marasmic types of cancer, the latter exhibiting an average reduction of thirteen per cent. of corpuscles, while the hæmoglobin fell to eighty-seven per cent. of the normal; the former showing a corpuscular reduction of thirty-five per cent.; while the hæmoglobin was as much as seventy per cent.

Linear Proctotomy.—At a recent meeting of the Academy of Medicine in Ireland (*The Lancet*), Dr. Ball defined the operation of linear proctotomy as the making an incision through the anus and rectum directly backward to the coccyx and hollow of the sacrum; the following being the indications for its performance: 1. For the cure of non-malignant strictures of the rectum, in which gradual dilatation by means of bougies or other instruments is either impracticable or inefficient. 2. For the removal of growths situated high up in the bowel or in the hollow of the sacrum. 3. As a palliative measure instead of colotomy in advanced malignant disease. 4. As a preliminary step to amputation of the rectum. Dr. Ball brought forward two cases illustrating the first class: Case 1. Male, twenty-three years of age, five years' syphilitic history. Considerable ulceration of lower part of rectum, with tight stricture above. Bougies gave rise to great irritation, so linear proctotomy was performed. Relief to obstruction was immediate, and the ulceration healed without further difficulty. There has been no recurrence of the stricture (twenty months after operation), and the amount of incontinence is extremely slight. Case 2. Female, forty-seven years of age, for five years suffered from a morphœa-like condition, which produced puckered subcutaneous cicatrices over both breasts, heart, and abdomen. She also had some ascites. The vagina was contracted, the uterus fixed, and a tight, smooth stricture of the rectum existed. This became so tight that her life was threatened from intestinal obstruction. The stricture, which would only admit about a No. 9 catheter, was divided, and all symptoms of obstruction obviated. Six months subsequently she developed stricture of the œsophagus, which proved fatal, no recurrence of the rectal trouble having taken place. The pathology of this case was doubtful, apparently not carcinoma; but as she died down in the country, no necropsy could be obtained. The following are examples of the removal of neoplasms by means of linear proctotomy: Case 3. Male, sixty-three years of age, rectum obstructed by soft tumor filling hollow of sacrum. An attempt to remove the mass by linear proctotomy was so far successful that the tumor, which proved to be a lympho-sarcoma, was completely extirpated; but, unfortunately, the patient died from septic peritonitis. Case 4. Male, twenty-six years of age, much worn down by the continuance of dysenteric-like discharge from rectum. A soft sessile growth could be felt at the highest limit accessible by digital examination, but, with the aid of linear proctotomy, it could be completely controlled. It was extremely vascular, and, in the patient's exhausted condition, destruction by Pacquelin cautery was deemed safer than extirpation. The patient recovered very perfectly, completely regaining his strength, and there has been, so far (eighteen months), no recurrence and no inconvenience from incontinence. Class 3. Dr. Ball did not consider that linear proctotomy could be favorably compared with colotomy for the relief of obstruction due to malignant disease. And in the fourth class, the consensus of surgical opinion was certainly in favor of adopting linear proctotomy as a preliminary to amputation of the rectum, and Dr. Ball had hitherto invariably practised it.

The "Normal" Diet.—According to Dr. G. Munro Smith, the daily destructive metabolism, which is the great criterion of work done, does not vary much among different occupations. Premising that he does not consider moderate over-eating injurious, he finds that very many men eat considerably more than the most liberal tables: it is not an uncommon thing for an average-sized man on very moderate work to eat 25 or 27 ounces of chemically dry food a day. Women eat much less than men, after making allowances for differences in weight and work. Where a man eats 19 ounces, a woman of the same weight and of active habits eats only 14 or 15 ounces. On a diet from which all meat is excluded he has found that 12 to 13 ounces *per diem* will comfortably feed a hard-working man. A moderate amount of stimulants appears to increase the average; moderately free drinking diminishes it. A diet consisting of one part of nitrogenous to seven or eight non-nitrogenous is a good combination; it is greatly exceeded on the nitrogenous side by the majority of men and women, especially the former. A diet of 12 to 14 ounces of chemically dry food, digestible, with the ingredients in proper proportion, is sufficient to keep in good health an average-sized man on moderate work. The majority of people (in England) eat literally twice as much as this.—*Bristol Medico-Chirurgical Journal.*

Tolerance of Operations on the Liver.—Professor Ponfick, of Breslau, has been for a number of years engaged in making experiments in regard to the relation between the liver and certain anomalies in the formation of blood. In the course of these investigations he has made some striking discoveries, which, although not directly connected with the object of his investigations, are yet of great importance. One of the most curious results of his experiments has been the discovery that the animal functions may be conducted without serious disturbance even after the loss of a very large portion of so important an organ as the liver (*The Medical and Surgical Reporter*, October 12, 1889). In some cases, operating with strict antisepsis, he succeeded in removing as much as three-fourths of the liver, either at several sittings, or in one single operation; and the animals upon which he experimented did not lose their lives, nor seem to be seriously disturbed in their health. In hundreds of experiments, in which he removed sometimes one lobe and sometimes another, the animals remained, in a considerable number of cases, perfectly well for months, and even for as long as a year. Clinical experience has already taught us that the whole of the liver is not absolutely essential to health, because large portions of this organ have been practically destroyed—as in the case of echinococcus and profound fatty infiltration—without any disturbance of the general functions of the body. But this, as Ponfick says, is hardly to be compared with the sudden and immediate removal of large portions of an organ which is supposed to be so important to health. The explanation of this curious fact seems to be that the liver has a wonderful power of reproduction. Ponfick found that, within a few days after the removal of portions of the liver, the work of its reproduction began, and that it proceeded with great rapidity to completion. In certain cases, he found that within a period of a few weeks as

much was reproduced as had been removed; that is, twice as much as had been left behind. These investigations have an interest altogether outside of that which is absolutely scientific, because it cannot fail to influence the development of abdominal surgery, if it is understood that large portions of the liver may be removed without serious danger to life.

Mitral Stenosis following Fracture of the Sternum.—Dr. Ritter relates the following case from among the out-patients of Professor Brieger (*The Practitioner*). A man thirty-four years of age, and always healthy, sustained in February a fracture of the sternum. He had violent pains in the breast, and hæmoptysis. The latter symptom persisted five days, while breathlessness, which was also present, did not disappear for four weeks. There was no increase of temperature or pulse. A careful examination at the end of five weeks revealed nothing in the heart and lungs, and the patient was allowed to leave the hospital. In July he appeared in the out-patient room. Since the accident he had suffered from nervousness, and was easily excited, while at times he had violent præcordial anxiety, constricting pain in the region of the heart, and severe palpitation. The sternum showed at the fourth rib a marked displacement of such a form that the upper end of the body was bent inward and formed a sharp angle with the lower part; the ensiform process was pushed to the right, and lay under the ribs for the greater part. In the cardiac region was a peculiar wave-like movement with a distinct thrill. The heart extended above to the upper edge of the fifth rib, to the left it reached to the parasternal line, to the right a finger's breadth over the right border of the sternum, and below to the seventh rib. A presystolic bruit was distinct, and the pulmonary second sound accentuated. The pulse was occasionally irregular, the wave small, and the tension low. Here there was a history of the heart being perfectly sound after the accident, while the palpitation of which he complained might be due to shock. The hitherto published cases of heart failure from causes similar to this have been caused by direct force which affected heart and bone together. One similar case has been published by Rose, of a cowherd who was gored by an ox in the region of the heart and sustained a fracture of the rib which healed in fourteen days. A year later he returned with well-marked heart failure and extreme dropsy, and he died soon after.

The Surgical Treatment of Perforation of the Stomach and Intestines following Ulceration.—Dr. Steinthal gives as indications for the performance of the operation of laparotomy, the sudden occurrence of severe pain referable to the abdominal region, accompanied by greater or less collapse, in individuals in whom a history pointing to ambulatory typhoid, typhlitis, or perityphlitis is obtained, and particularly if these symptoms have followed an act of vomiting or other powerful exertion or straining effort. To these are added the objective signs of peritonitis, which develop much more quickly after a perforation than in cases of obstruction or occlusion of the bowel, and if free gas is found in the abdominal cavity (peritoneal meteorism) the diagnosis between perforation and acute diffuse peritonitis is comparatively easy. The latter is distinguished by the absence of every motion of the intestinal canal usually recognized through the abdominal walls by the sight, feeling, and hearing, and likewise of the hepatic dulness, and when a doughy condition of the epigastrium with a well-marked and generally high percussion note is distinguished. Czerny attempted to lay down rules in guiding the surgeon to a conclusion regarding the location of a perforation. Odorless gas with slight septic qualities, upon opening the peritonæum, indicates stomach perforation. Steinthal adds to this, rapid disappearance of the line of dulness, and almost constant absence of vomiting. In cases of perforation of the ileum, gas of septic odor and qualities appears; in perforation of the jejunum, slight exit of the intestinal contents and gradual appearance of the symptoms occur. Up to the present time twenty-three cases of laparotomy for ulcerative perforation have been reported, of which number ten have recovered. In the fatal cases it has not been found that the operation itself has lessened the patient's chances of recovery, or that circumscribed has been connected with general peritonitis, as has been until now the generally expressed fear on the part of medical practitioners. As to the technique of the operation, in cases of circumscribed peritonitis following perforation near the surface, the peritoneal contents are evacuated by incision; and if the place of perforation is accessible, the same should be at once closed by sutures, avoiding as much as possible further manipulation, and leaving further procedure for the future. If the perforation is not localized and the peritonitis general, the peritoneal cavity should be freely opened, in order to get a clear view. If the perforation be supposed to be in the cæcum, a lateral incision is recommended; in perforation of the stomach and duodenum, an incision in the linea alba from the umbilicus upward, with perhaps the addition of a cross-incision; in the case of the jejunum and ileum, a long incision in the median line. The peritonæum should be opened at first by a small incision, in order to confirm or amend the diagnosis by the escaping gas. It may happen that the bowel-loops, despite the perforation, are still much distended, and their return into the abdominal cavity is attended with some difficulty. We succeed rather easily in overcoming this difficulty by Kümmel's method, with antiseptic compresses. He recommends, after the manner of Mikulicz, flooding the abdominal cavity, after closing the perforation, with a one-sixth of one per cent. solution of salicylic acid, and drying the loops of intestine and all available parts with tupfer wrung out of 1–200 sublimate solution. Drainage is recommended by means of iodoform wicking, after Gersuny's plan.—*The Brooklyn Medical Journal.*

Plastic Bronchitis.—Dr. Samuel West has continued the work commenced some years ago by Lebert, and has collected together all the recorded cases of plastic bronchitis which have occurred since the year 1869. Fifty-two cases have been reported during the twenty years, and the result of a critical examination of these is here given. The majority of the cases being of a recurrent type, no attempt has been made to follow Lebert in his classification of plastic bronchitis into acute and chronic groups. The only case seen by the author was that of an otherwise healthy woman of forty, who for the previous two years had been subject to regularly recurring attacks of extreme dyspnœa, followed by free expectoration in which casts were discovered. These were small, grayish white, and much ramified. The largest were not thicker than a goose-quill, many being much smaller. The attacks came on at 2 A.M., and lasted from two to three hours. No special symptoms or physical signs were observed either during or between the attacks. No relief was afforded by treatment. Examination of the records of other cases showed a preponderance of cases among males, especially in early and middle life. Some of these were associated with other acute and chronic inflammatory conditions of lung or pleura, but no direct connection between them could be made out.

The symptoms produced were, in the majority of cases, those of dyspnœa and cough, followed and relieved by free expectoration. The dyspnœa has rarely proved fatal. The physical signs are those of bronchial catarrh, unless some other affection of the lung be present. The sputum is muco-purulent, for the most part, and the casts are found intermingled with it. Neither the Charcot-Leyden crystals nor the spiral threads of Curschman have been discovered in association with them. The casts were most frequently expectorated at night. Hæmoptysis has occurred in some cases, but has generally ceased with the evacuation of the casts. The course of the temperature varies with individual cases, sometimes rising with the

formation of the casts and falling again after their expectoration. The access of the disease is generally very sudden, without premonitory symptoms. Each attack may last but a few hours, but there is a strong tendency to recurrence at varying intervals, extended in some recorded cases to several years. The liability to the disease would seem to last through life. Of its etiology nothing certain is known. Treatment up to the present time has been singularly unsuccessful. Iodide of potassium and lime-water inhalations have been the only drugs for which the least result has been claimed.—*The London Medical Recorder.*

Formulæ for the Administration of Creasote.—Dr. Keferstein has published some good formulas for the administration of creasote.

℞. Creasote..... gr. xx.
Alcohol..... ʒ vj.
Cinnamon water..... ʒ iij.
Cinnamon syrup..... ʒ vj.
M. One tablespoonful three times daily.

For the pill-form the following is recommended:

℞. Creasote..... gr. lx.
Powdered marshmallow root,
Purified liquorice.....āā ʒ jss.
Mucilage of gum arabic..... q. s.
M. Div. pill. No. cxx., coat with gelatin. Sig.: One pill three times daily.

In irritative cough and diarrhœa the following is administered:

℞. Creasote..... gr. xxx.
Acetate of lead,
Opium (pure).....āā gr. v.
Extract of liquorice..... ʒ jss.
Mucilage of gum arabic..... q. s.
M. Div. pill. No. 50. Sig.: One pill three times daily.

For children creasote in the form of the following emulsions seems best adapted:

℞. Creasote..... gr. xx.
Dissolve in almond oil..... ʒ j.
Gum arabic..... ʒ v.
Water..... ʒ iij.
M. Make an emulsion and add
Comp. tinct. of orange-peel..... gtt. xv
Oil sugar of peppermint..... ʒ j.
M. One teaspoonful two to five times daily.

For drop doses the author uses the following:

℞. Creasote..... gr. xlv.
Tincture of cinnamon..... ʒ j.
M. Fifty drops three times daily in half a cup of warmed milk or Malaga wine.—*Deutsche Medicinische Wochenschrift.*

The Development of the Malarial Parasites in Tertian Fever.—Dr. Golgi asserts that, similarly as in quartan fever, so in tertian fever the origin of the disease is an amœboid organism which enters the red blood-corpuscles, and then goes through certain stages of development, which, in regard to succession one upon another, and in regard to symptoms, appear with unchangeable regularity (*The London Medical Recorder*, October 21, 1889). As soon as the infection has taken place, and the typical clinical forms of tertian fever have developed, there is always positive proof forthcoming of a characteristic condition, whether before or during or after the fever attacks. With numerous preparations and drawings Golgi describes the various phases of development, and the different species of parasites in simple tertian fever. He also explains the observations he has made in clinical cases of mixed fevers. Thus, in the blood of a patient with treble quartan fever there were three distinct generations of parasites, which came to maturity always one after another, day by day. The examination of the blood was confirmed by the regular succession of a violent, a medium, and a very slight attack. As to their biological properties the parasites of the tertian fever are thus distinguished from those of the quartan fever: 1. By the completion of their development-cycle in two instead of three days, as in quartan fever. 2. By the different character of the amœboid movements, which are more active in tertian fever. 3. By the relation of the parasite to the red blood-corpuscle that harbors it. While in quartan fever the substance of the attacked blood-corpuscle maintains its characteristic yellowish-green color until the last phase of distinction, the action of the parasite of the tertian fever on the other hand is very early discerned, the blood-corpuscles losing their color, even when the parasites occupy as yet but a small portion of them. This rapid decoloration appears to be connected with the rapidity with which the parasite sends out its protoplasmic shoots into all parts of the blood-corpuscle—even to its periphery. In respect of their morphological properties, too, the two kinds of parasites differ. 1. The protoplasm of the quartan fever parasite has a much finer appearance. This is chiefly observable in the early phases of development of each kind. 2. In quartan fever the pigment appears in form of thicker grains and bacilli, which in tertian fever are of extreme delicacy. 3. The process of separation differs in an extraordinary degree in the two kinds of parasites. According to Golgi's views the numerous varieties of intermittent malarial fevers are simply varieties or combinations of the two chief types—the tertian and quartan fever.

The Influence of Drugs on Putrefactive Processes in the Intestine.—Dr. Stieff reviews the experiments and writings of those who have shown that such substances as phenol, indol, skatol, and kreosol, found in the urine, are really products, in the healthy individual, of decomposition going on in the intestine under the action of the micro-organisms of putrefaction. In individuals in whom there is some putrefactive process taking place elsewhere in the body, owing to some pathological condition, these substances will appear in the urine in excess. There will also be a similar increase when the absorption from the intestine of the normal products of digestion is insufficient or interrupted. He next discusses the experiments which have been made to determine whether the introduction of antiseptic materials into the intestine would not interfere with the decomposition of albuminous bodies there. As he does not regard the results of these experiments as conclusive, and as it is important to possess some substance which has this power of checking putrefaction in the bowel, he himself undertook some investigations on the subject, performed on a series of patients in Gerhardt's clinic. The drugs employed were calomel and camphor, and careful analyses were made of the urine while they were being given. The experiments he details fully, and sums up the results in the following conclusions: 1. Calomel, given in doses of five grains three times a day, exhibited no disinfecting power in conditions of increased decomposition in the intestine. 2. Consequently it can scarcely be recommended for the purpose of checking putrefaction in the intestine, on account of the large dose which would need to be employed. 3. Camphor appears to possess a slight restraining power on putrefaction, since, in two cases, doses of five grains three times a day, produced a diminution of the intestinal decomposition. 4. This action of camphor does not appear at once, and is only distinct after two or three days.—*The American Journal of the Medical Sciences*, December, 1889.

Sweating of the Feet.—The result of extensive experiments in the German army as to the best treatment for excessive sweating of the feet has been to prove the great superiority of chromic acid over all other applications. Of 18,000 cases in which chromic acid was used, forty-two per cent. were reported "cured," fifty per cent. "improved," and only eight per cent. "unrelieved." The feet are first bathed, and, after being thoroughly dried, a five per cent. solution of the acid is applied with a brush. Two or three applications suffice, as a rule, but the treatment has sometimes to be repeated after a fortnight. *British Medical Journal.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

New York, January 18, 1890.

THE HEART LESIONS AND HEART SYMPTOMS OF CHRONIC ENDOCARDITIS.

REALIZING that the common diseases are of most interest to the practitioner, Dr. Delafield (*Journal of the American Medical Association*, October 19, 1889) draws attention to some prominent features of the above disease, observed by him in his practice and in post-mortem examinations. Nearly half of his paper is devoted to a classification of the associated kidney diseases, to which we need not at present refer.

Chronic endocarditis is a very common disease, presenting a great variety of symptoms and many degrees of intensity. Taking for example the valvular diseases, which are most easily observed, we find that of two patients with the same valvular lesion one may enjoy good health and attend to his daily work, ignorant perhaps that he has any disease; while the other presents very serious, perhaps fatal, symptoms. In order to treat the patient properly, we must search out the cause of this difference in the symptoms.

It seems clear that most of the important symptoms, such as the dropsy and the disturbances of assimilation, as well as the brain and lung complications, are due to abnormal blood-supply to the tissues. Why, then, is the circulation disturbed in some cases and not in others? It is evident that the difference is not due simply to the amount of interference with the mechanical functions of the valves. Of course, many of the symptoms are closely connected with disease of the kidneys, which are often seriously affected when a superficial examination of the urine gives negative results, and which are rarely found healthy in fatal cases; yet many patients are free from kidney complications. Apart from the condition of the kidneys, the most important causes of variations in the intensity of the symptoms are, perhaps, the *intensity of the endocarditis*, and the *irregularities in the action of the heart*.

In some persons the heart symptoms which follow the first attack of endocarditis are due simply to mechanical injuries produced by the inflammation and left behind by it, the inflammation itself having disappeared, never to return. They suffer from deformity, not from disease. The changes in the cavities and walls of the heart which result from such deformity are not as likely to follow as when chronic disease is left.

Chronic endocarditis may, especially in children, directly follow the acute form, or it may be chronic from the first, or it may be developed in damaged valves long after an acute attack. It varies greatly in intensity at different times, and may suddenly cease altogether, but its general tendency is to persist and to involve new portions of the endocardium, although its progress may be checked for a time, now and then. It is a productive inflammation, with the formation of new tissue, but without exudation.

There are two conditions seen in different patients, or at different times in the same patient.

The *more active* form presents very considerable growth of cells and also a death of cells, so that the inflamed endocardium is thickened in some parts, and ulcerated in other parts, upon which thrombi are apt to form. Many such cases prove fatal in six or seven weeks, and many more within six months. The patients suffer intensely from disturbed heart-action; delirium, convulsions, paraplegia, cough, hæmoptysis, dyspnœa, nausea, vomiting, dropsy, loss of flesh and strength, and anæmia, and a rise of temperature. Although the tendency is downward, the patient may experience temporary or permanent relief from the inflammation at any time. As the inflammation is active, rest in bed, the use of cold or of counter-irritation over the heart, are likely to be of value.

The *less active* form presents thickening of the basement-substance, with more moderate growth of cells, and without cell-death. There is some roughening of the surface, with small vegetations, but no thrombi form. The cases continue for years, with intermissions. Many exhibit no symptoms at all. Many present one symptom after another. The best treatment is an out-door life with as much exercise as they are able to take.

In either of these forms, degeneration or calcification of the inflamed endocardium or of the thrombi may occur.

Abnormal heart action is generally a serious symptom of the disease, although it is absent in some cases. It may arise from the intensity of the inflammation, from advanced stenosis or insufficiency of the valves, from dilatation and hypertrophy of the ventricles; and in rare cases very intense disturbances may be caused by chronic myocarditis and diseased conditions of the coronary arteries.

A very important cause of irregular heart-action is contraction of the smaller arteries, with increased arterial tension and venous congestion. The cause of such attacks is unknown. They may occur frequently or infrequently, lasting for hours, days, or months; the heart-action becomes at once rapid, forcible, feeble, and tumultuous, in proportion to the degree and suddenness of the arterial spasm. These paroxysms are not determined, as to their severity, by the severity or extent of the endocarditis. Thus a patient with incipient disease may suffer greatly with precordial pain on lying down, and with dyspnœa on exertion, the health being otherwise good and the urine normal, though the heart is enlarged and the radial pulse tense—the symptoms yielding readily to remedies (such as nitrite of amyl, chloral, nitro-glycerine, opium, and potassium iodide) which dilate the arteries; while another patient, with advanced and progressive disease, may feel well except when paroxysms of arterial contraction occur. The remedies above mentioned gradually fail to relieve the paroxysms. The attacks become more frequent, the

pulse becomes tense but small, the heart's action feeble, or tumultuous and weak. Out-door life is then the best remedy, with well-regulated exercise. As the disease advances stenosis or other valvular changes become marked and the patient is compelled to keep quiet. Sometimes a patient with old progressive disease, without marked, symptoms, will, upon intercurrence of a slight pleurisy or pericarditis, suffer a sudden and fatal attack of contraction of the arteries, with dyspnœa.

There are certain cases—where the endocarditis may be very mild—in which an obscure form of irregular heart-action of nervous origin occurs. The changes found after death are various. The treatment is difficult, and relief is uncertain.

WHAT SANITARY REFORM CAN DO FOR A CITY.

The Secretary of the Tennessee State Board of Health, Dr. J. Berrien Lindsley, has prepared an article for the forthcoming report of the Board which shows in a striking manner how the health of a large community can be benefited by the intelligent efforts of a few active individuals who have the support of public opinion. The article deserves to be studied by sanitarians everywhere, if only as an encouragement to them to persevere in their apparently thankless task, often against the greatest odds.

Dr. Lindsley's paper is a history in brief of the work of sanitary reform in the city of Nashville, which work was begun in 1874, the immediate incentive thereto being the devastation wrought by the last cholera visitation.

"The Board of Health, as organized in Nashville, consisted of the Mayor, *ex officio*, and of four physicians, chosen by the City Council, with a medical Health Officer exclusively devoted to the work. The city was then small and very poor; hence the Board moved cautiously. No extravagant system of sanitary engineering was urged, no bonds issued, no debt incurred. The first steps were the registration of deaths and thorough local sanitation. Rigid house-to-house inspection by first-class officers was steadily pursued. Health ordinances impartially and uniformly enforced. A complete sanitary survey of Nashville was taken early in 1877, a thing which had not at that time been attempted in any Southern city, and, indeed, in only one or two in America. Its value can hardly be computed. Besides giving that information without which a Board of Health moves in darkness, it is an educator without equal. An intelligent and respected member of the police force, well known and well liked by all the community, visited every house and every building in detail. With suitable memorandum-books, he entered the results of his inquiries. Thus, in a few months, everyone in Nashville was initiated into the work undertaken by the Board—that of making Nashville a city renowned for health and proof against epidemic scourges."

During the epidemic of yellow fever in Western Tennessee, in 1878, Nashville became a veritable city of refuge, and its Board of Health had an opportunity to demonstrate the efficiency of individual isolation and perfect sanitary preparation. The healthfulness of the city at this time was so universally ascribed to the efforts of the Board of Health, that the citizens gave them an ovation as a mark of gratitude and public appreciation of their services. This public demonstration was, of course, of far-reaching benefit in impressing upon the entire community the undoubted value of sanitary reform.

In the fall of 1883 the Board of Public Works came into existence, and at once began the work of remedying the great defects made apparent by the sanitary survey. These were, especially, the deficient water-supply; the almost total lack of drainage; the miserable condition of the alleys; and the pressing need of improved streets and sidewalks in many portions of the city. The progress made in each of these lines has been progressive and most satisfactory. The city has now twenty-five miles of sewers, and the new water-works, nearly completed, will furnish a daily supply of thirty million gallons.

But of more interest than a mere statement of what has been done in the way of sanitary improvement is a comparison of the results following these improvements. This can be stated in very few words:

In 1877 Nashville occupied an area of scant three miles, with a population of 27,000, and a death-rate of 34.55 per 1,000 yearly. Now it has an area of 4,021 acres, or six and one-third square miles, with a population of 68,531, and a death-rate of 15.31.

As Dr. Lindsley justly says, this is progress. It is true that Nashville is favored by its position, and it would be a disgrace were it not a healthy city; but that should be no cause for discouragement for other less favored localities. Even the City of Mexico, built as it is almost in a swamp, is destined, without doubt, to become one of the healthiest cities in the world when the huge sanitary work now in course of construction is completed. Nashville was not a healthy city before Dr. Lindsley and his associates took hold of it, and it is now what they, and others inspired by their zeal and enthusiasm, have made it; and there is no valid reason why every other city and town in the country should not be improved in the same way, if only the right men can be found to undertake the task. They certainly ought to be urged at least to try, after reading of what Nashville has accomplished quietly and as a result of patient effort.

POLITICS AND HOSPITAL SERVICE.

We do not pretend to be familiar with the ins and outs of politics in the City of Brotherly Love, for it is a sufficiently bewildering task to follow all the intricacies of our own local politics; but certainly the Mayor of Philadelphia, if we may trust the tales which are told of him, must have strange ideas of the duties and responsibilities of his office. In order to satisfy a personal grudge, it is said, Mayor Fitler not long ago removed Dr. White from the position which he held as head of the Directors of the Department of Charities and Correction in Philadelphia. Dr. White had long filled this responsible position most ably and satisfactorily, and there was no fault to be found with his administration; but the Mayor wanted his scalp, and he got it. He has now turned his attention to Dr. J. William White, a son of the elder Dr. White, and is reported to have given orders to the Directors of the Department of Charities and Correction to remove Dr. White from the surgical staff of the Philadelphia Hospital.

Dr. White has been on the staff of this hospital for fourteen years, being now senior surgeon. Of his faith-

fulness and devotion to duty in the hospital there is no question, while of his professional fitness we need not speak, for his reputation as an able and skilful surgeon has long since ceased to be local. As nearly as we can see, Dr. White is called upon to resign his work in the hospital for no other reason than that his father would not become the political tool of the Mayor. We sincerely trust that the Directors of Charities and Correction will not lend themselves to the spite of Mayor Fitler, but that they will refuse to obey his order to remove a conspicuously efficient medical officer simply because the father of the latter has incurred the autocrat's displeasure.

THE EAR TROUBLE OF THE EMPEROR OF GERMANY.

We learn from the London *Truth* that the Emperor of Germany is again laid up with his ear trouble, chronic suppurative otitis media, and, in consequence of pressure of business, is dangerously temporizing with the treatment advised by his medical attendant. With a hereditary predisposition to scrofula and a consequent chronicity of the affection, it will be a question of time only when the affection shall take an incurable turn, and invite directly an extension of inflammatory action to the meninges, which may jeopardize the life of the distinguished personage. In this country we are taught that such an affection is curable by surgical interference, and the veriest pauper here has a chance equal to that of a king.

SIMPLE AND SUCCESSFUL TREATMENT OF A CASE OF SNAKE-BITE.

There are many vaunted remedies for rattlesnake-bite which have one peculiarity in common, namely, that they are never at hand in time of need. Consequently the most serviceable and most frequently used remedies are those which are found in every home, whiskey taking the lead. Ammonia is also of great value on account of its therapeutic qualities, and because it is a household article. In the *Medical News*, September 14, 1889, Dr. Memminger relates a case in which he combined the use of these remedies with a very skilful and ingenious application of compression bandages, in a way which is well worthy of thoughtful consideration.

The patient, a negro, thirty years of age, was bitten in the forefinger of the right hand by a rattlesnake two feet and a half long. He cried for help, ran some fifty yards, and fell, unconscious. A friend at once put a ligature about the arm, and poured half a pint of whiskey down his throat. When Dr. Memminger saw him, about ten minutes after the accident, the arm was enormously swollen, rather from the poison than from the ligature, and the patient was completely unconscious, with pulse thirty to the minute, slow respiration, cold limbs, and escape of fæces. Although the case seemed hopeless, he made a free incision through the wound to the bone, cutting both vein and artery of the finger, and applied Esmarch's tourniquet just below the shoulder. Then, with Esmarch's elastic bandage, he drove as much blood as possible out of the arm, working from the tourniquet downward, and causing the wound to bleed freely. The tissues through which the incision passed were almost black, and the blood, of which about a quart was lost, failed to coagulate. Twenty minims of a solution of ammonia in water (1 to 3) were thrown into the median basilic vein, and this injection was repeated in half an hour.

At the end of an hour after the accident the patient was able to sit up and talk with his friends. It was evident that that portion of the venom which had passed the ligature had now lost its effect upon the system. But how much venom still remained in the arm below the ligature could not be known. Dr. Memminger therefore determined to allow this residual portion of venom to be absorbed into the system in small doses.

The tourniquet was loosened for about three pulse-beats. The patient at once fell into unconsciousness as profound as before, and seemed in as great danger as at first. Ammonia was injected, once only, in the same manner as before. In an hour the patient had rallied. Six times within seven hours the tourniquet was loosened, and each time collapse followed, and revival within an hour under a single injection of ammonia. At the end of the seventh hour the tourniquet was taken away, the wound was dressed with boracic acid, and the patient was taken home delirious. Two days later he walked to the office to have his finger dressed. The hand was painful, and erysipelas threatened, but did not occur. In a few days the patient was entirely well.

MUNICIPAL LODGING-HOUSES.

The timely article of Dr. Crampton in the present issue calls attention to a matter of great importance in connection with the proper care of the large number of police-station lodgers of this city. The law to which he refers gives ample power to the Commissioners of Charities and Correction, and, in the absence of any argument to the contrary, offers no excuse for its non-fulfilment. The truth, as Dr. Crampton graphically depicts, needs nothing more than the mere telling to prove the crying necessity for reform of the present lax system. The police stations are more than overcrowded, are badly ventilated, and the lodgers, many of whom are unfortunates out of employ, are treated little better than dogs. There is no excuse for this state of affairs, and every humanitarian will rejoice that the subject is brought up in a shape to challenge discussion and stimulate action on the part of the proper authorities.

IS MEDICINE A SCIENCE?

This ancient inquiry comes up for discussion at periodic intervals. The aphoristic sayings of various learned and satirical men of olden time are quoted to the end that medicine may be shown to have not a scientific peg to stand upon. And the general result of the discussion is what, in sporting parlance, may be called a knock down for the other side.

Medical men who are aware of both the strength and weakness of their calling will best answer the question by saying at once that medicine is not a science, nor does it pretend to be. It is an art; that is to say, it is a practical application of special knowledge, and manipulative skill. The real question comes, then, whether the medical knowledge upon which our art is based is really scientific knowledge, *i.e.*, knowledge which is coherently and logically

classified. And the answer of course is, that some branches do truly belong to science, while some do not. Anatomy, chemistry, physiology, pathology, are all, in the highest sense of the word, scientific studies. Therapeutics is certainly not, though it is much nearer to science and further from empiricism than it used to be. Therapeutics is what is popularly meant when medicine is spoken of, and hence we must answer the question, "Is medicine, practically applied, based upon scientific rules and rigidly classified knowledge," in the negative. Medicine is an art with much science, but more empiricism, as a basis. It could not be practised properly without scientific knowledge, or carried on successfully without the teachings of empiricism. But every year the scientific element grows more important, and more dominant in its relation to empiricism. The medical art can never emancipate itself entirely from the latter, but in time we can hope that it will yet gain its strongest help from the former.

News of the Week.

The Epidemic of Influenza is still on the decline, and will probably disappear within a few days with the incoming crisp weather. In the meantime everybody will have had the disease, or will believe they have had it, as it is too fashionable at present to allow of any different probability. The "grip" is charged with accountability for every dereliction of duty, every missed engagement, every indisposition for work, and compasses the diagnosis and tinges the complexion of every other malady. If everyone who has had an ordinary cold has suffered from the grip, the latter disease must be very prevalent indeed. And who is there who dares dispute the fact when the patient makes his own diagnosis, and who reads the absurd sensational accounts of the supposed dreadful ravages of the disease as given in the daily press?

Section on Diseases of Children, Academy of Medicine.—Dr. L. Emmet Holt has been elected Chairman, and Dr. Walter Lester Carr Secretary, of this Section.

Death from Ether.—Coroner Levy held an inquest January 13th in the case of Stephen Gillen, a painter, twenty-eight years of age, of 147 Cherry Street, who died from etherization in Bellevue Hospital in November last, under an operation for removing an ulcer from the neck. Dr. Dunham, of Bellevue, was in charge of the operation, and was assisted by Dr. John Brooke, Dr. Stewart, and Dr. Paton. Dr. Brooke administered ether under the direction of Dr. Dunham, and the patient died. Dr. Gerster testified that the patient would have died of fatty degeneration of the heart whether chloroform or ether had been administered, and that it was impossible to previously determine whether the patient had fatty degeneration or not. The jury exonerated the physicians in charge.

A Million Dollar Hospital for Pittsburg.—The will of the late John H. Schoenberger, the millionnaire Pittsburg iron-master, was filed in Surrogate Ransom's office January 13th. He made this fortune in Pittsburg, but during the last few years of his life he lived in this city, where he died on November 13, 1889, leaving a fortune estimated at $4,000,000. He bequeaths nearly $1,000,000 in money and real estate to establish a public hospital in Pittsburg as a memorial to his first wife, Margaret Shoenberger. It is to be called "The St. Margaret Hospital." He bequeaths, as a site for the buildings, a plot of ground three hundred by four hundred feet at Forty-sixth and Davidson Streets, in Pittsburg, and provides that three-fourths of the institution shall be devoted to the lodging and care of general patients, and one-fourth for the shelter and care of incurables. For its support he bequeaths $550,000, $250,000 of which is to be expended on the building, which he directs shall be made as near as possible to the design of St. Luke's Hospital in this city. He directs that $35,000 shall be expended on the grounds, and $65,000 in furnishing the hospital; the balance to be held by the hospital corporation as a permanent fund for the maintenance of the institution. Another clause bequeaths an additional $250,000 to this permanent fund. He expresses a wish that the Diocesan Convention of the Protestant Episcopal Church shall, within two years after his death, select nine laymen to organize the hospital corporation. In case the Convention declines to do this, he requests his trustee and executors to make the selection.

The Infant King of Spain, who, during the past few days, was considered in a critical condition, is now reported out of danger. The statement that the disease from which he was suffering was tubercular meningitis is now believed to be erroneous, the febrile symptoms being due to an attack of capillary bronchitis, which was a complication of the influenza from which he had been suffering. At best, however, he appears from his likeness to be a feeble son of a feeble sire. With an hereditary taint of scrofulosis, and with a necessarily strong predisposition to phthisis, the chances of a long life are very much against him, not the least of which is shown in his large rachitic head and his comparatively puny body. Under the latter circumstances, a high temperature with mental hebetude and accompanying languor were ominous symptoms which pointed with almost reasonable certainty to the probable involvement of the meninges by a tuberculous deposit.

Nobody Wants the Hospital.—A county hospital has just been completed in Omaha, but the contractors cannot get anybody to accept it and take it off their hands. The county commissioners refuse to accept the hospital except from the hands of the architect, and the latter for some reason cannot be found. The result is that the contractors have a very fine hospital on their hands, but do not know exactly what to do with it.

Lengthening the Term of Study.—The Royal College of Physicians in Great Britain has passed a resolution that the medical curriculum shall be lengthened to five years, instead of four as at present.

A Plea for Many Medical Schools.—A contemporary from the banks of the muddy Missouri contends, in a long and earnest editorial, that there are not too many medical colleges in the United States, seeming to hold the view that Beecher used to hold concerning religious sects, that the more there are of them the better. The editor ought to know whereof he speaks, for he is secretary, professor, demonstrator, and possibly other things, in his own local school.

The Death of Professor Von Troeltsch, of Wurtzburg, the celebrated specialist in ear diseases, is announced.

Patented German Drugs.—According to Dr. F. E. Stewart, *New York Medical Times*, sulphonal (as well as some other German drugs) is both patented and trademarked in the United States. Sulphonal is sold here for $1.35 per ounce, while in Germany it is free and sold for about forty cents per ounce.

Regulating Matrimony.—A bill has been introduced into the Legislature of Kentucky, which prohibits marriage with an idiot, lunatic, pauper, vagrant, tramp, drunkard, gambler, felon, or any person rendered physically helpless or unfit for the marriage relation, or any person with a violent temper, or who has within one year been a frequenter of any immoral house.

Medical Experts.—At a meeting of the Kings County Medical Society, January 14th, the following resolution was discussed: "*Resolved*, That it is the sense of this society that the physicians who are called upon to give evidence in legal cases with reference to the existing condition of patients, should insist, if it be possible, upon meeting in consultation the physicians to be called by the other side, so that there may be a full interchange of views before they give their evidence." Members of the legal profession were invited to take part in the discussion of this question.

Curious Lunacy Legislation.—The Rhode Island Legislature has passed a law compelling the Supreme Court to appoint a commission for every patient who should make application for one. The Supreme Court has decided that no insane person can be held without "due process of law," and it has also been declared that the statutory process is not a "due process of law;" hence it is a question if a person can be confined in a Rhode Island insane asylum at all, except after trial by jury.

A New Medical Library for New York.—A nucleus for another medical library and rendezvous in New York has just been brought into possibility, says the *Journal of the American Medical Association*, by the junction of the Mott Memorial Library and the State Medical Association. They have five thousand volumes and eight thousand volumes, respectively, and most eligible headquarters at 64 Madison Avenue. They have a small fund each, and the opportunities for a steady increase in a membership of seven hundred physicians in the State Association. In union there is strength, and it will appear to most persons very unwise to attempt the great expense of establishing and keeping up another medical library in this city.

Cheap Medication.—A bill has been introduced in the Legislature of the State of New York incorporating the People's Co-operative Medical Association of Brooklyn, which is to furnish cheap medical attendance and medicine. Capital, $1,200.

Investigation of Electrical Execution in France.—The medical section of the French Academy of Sciences will investigate the subject of execution by electricity. The inquiry will be aided by the expert electrician, Marcel-Desprez. The visit of the American inventor, Edison, and his presentation before the Academy of his views concerning the painless and instantaneous extinction of life by electricity, have been the incentives to this investigation.

Is Suicide a Crime?—An interesting question has just been discussed and decided by the Court of Appeals, in the case of Darrow against the Family Fund Society. James H. Darrow, a policy-holder in the defendant society, died in the State of New York from the effects of poison taken by him, and which was administered by himself with intent to take his own life. The insurance contract contained a clause that it would be void if the assured should die "in violation of, or attempt to violate, any criminal law of the United States, or of any State or country in which the member herein may be." The judge decided in favor of the plaintiff, although to commit suicide is contrary to the laws of this State.

A Ladies' Medical Society has been organized in this city, under the title of the Alumnæ Association of the Woman's Medical College of New York. At a recent meeting the subject of basilar kyphosis was learnedly set forth.

The American Society for Psychical Research will, it is said, abandon its organization after its next annual meeting. This is a confession that it could find no ghosts, and no clairvoyant or telepathic phenomena.

To Suppress a Bogus Medical College.—The Rutland, Vt., physicians are moving for the suppression of the bogus medical college of that town.

The Chloral Treatment of Scarlet Fever is strongly recommended by Dr. Wilson, of Philadelphia. He gives the drug in doses of gr. j. to gr. v.

Annual Meetings.—Most of the county and other local medical societies hold their annual meetings during this month. The following are two that have just been held: The sixth annual meeting of the Amsterdam (N. Y.) Medical Society was held on January 7th, and was followed by the usual dinner. The following officers were elected for the ensuing year: President, Dr. W. H. Robb; Vice-President, Dr. R. G. Johnson; Secretary and Treasurer, Dr. C. F. Timmerman; Executive Committee, Drs. Robb, Timmerman, and French; Pathological Committee, Drs. Stover and MacMartin. The meeting of the Luzerne County (Pa.) Medical Society was held on January 8th. Dr. G. W. Guthrie was elected President, and Dr. Morris Gibson, Secretary and Treasurer.

The Annual Meeting of the Hartford (Conn.) Medical Society was held at the residence of Dr. Russell. This was the twenty-fifth year that the annual meeting has been held at Dr. Russell's, and it is regarded as quite a social occasion by the Society. The officers elected for the ensuing year were Dr. Russell, President; Dr. Stearns, Vice-President; Dr. Taft, Secretary; Dr. Alton, Treasurer, and Drs. Hudson, Shepherd, and St. John, Censors. The members of this Society expect soon to build a hall with laboratory, museum, library, and lecture-rooms.

A Woman President of a Medical Society.—At the annual meeting of the Montgomery County (Pa.) Medical Society, held in Norristown on January 8th, Dr. Alice Bennett was unanimously elected President. The other officers chosen were as follows: Vice-Presidents, Dr. D. R. Bergey and Dr. Henry T. Sykes; Recording Secretary, Dr. H. H. Whitcomb; Corresponding Secretary, Dr. J. B. Carroll; Treasurer, Dr. Ellwood M. Corson.

The Middleton Goldsmith Lecture.—Professor William Pepper, of Philadelphia, delivered the Middleton Goldsmith Lecture before the New York Pathological Society, in the hall of the Academy of Medicine, on Wednesday evening last. The subject of the lecture was "Hepatic Fever."

Presentation of Portraits of the Founders of the Pathological Society.—On Wednesday evening, before the delivery of the Middleton Goldsmith Lecture, a presentation was made to the Pathological Society of the portraits of Drs. Middleton Goldsmith, Lewis A. Sayre, and John C. Peters, founders of the society. The presentation was made on behalf of the donors by Dr. William P. Northrup. In his address the speaker sketched briefly the origin of the society, and drew a very happy picture of the first meeting at Dr. Sayre's office. The President, Dr. Roosevelt, accepted the gift for the society. He drew attention to the fact that as yet pathology had advanced medical science but little toward its true object, the cure of disease, but he believed that the time was coming when this object would be attained, and when, by a more perfect knowledge of the beginnings of disease, its treatment would be more rational and more satisfactory in its results.

The Boston Board of Health has added membranous croup to its list of contagious diseases.

A New Biological Laboratory has recently been built and handsomely equipped for the University of Toronto.

A New Diuretic, called "Duretin," has been recommended by Dr. Gram, of Copenhagen. It is chemically the obromium-natrium salicylicum, and resembles caffein, except that it has not its exciting effects. The dose is 15 grains.

The York County (Pa.) Medical Society held its annual meeting on January 2d, in York. After the election of officers the Society adjourned to the City Hotel, to partake of its annual banquet. Dr. I. C. Gable, of York, was elected President for the ensuing year, Dr. D. K. Gotwalt, Secretary, and Dr. L. Frey, Treasurer.

Why Reporters are Excluded.—The Chicago Medical Society has a rule prohibiting reporters from attending its meetings, yet, despite this, much of its discussions on any topic of public interest manage to ooze out. At one meeting a member stated that tincture of myrrh, given every fifteen minutes, was an infallible cure for diphtheria. He had had one hundred cases without a death. This promptly appeared in the daily papers. It was certainly a very interesting item of news.

The Philadelphia Hospital.—Our Philadelphia brethren are much stirred up by the recent action of the Board of Charities regarding the staff of the Philadelphia Hospital. The *Medical and Surgical Reporter* says: "The Board of Charities and Correction of Philadelphia met December 30th, and by a solid vote of those of its members who are supposed to be the creatures of the Mayor, displaced nine members of the medical staff of the hospital, against whom no charge of unfitness could be brought, and put nine new men in their places. This action has brought upon the unworthy members of the Board the condemnation of every newspaper in Philadelphia which is deserving of respect."

A New Hospital in Baltimore.—The Garrett Free Hospital for Children has recently been opened in Baltimore.

Homœopathic Druggists and the Law.—The members of a prominent homœopathic drug firm in this city have been brought into court, on complaint of the Board of Pharmacy, for violating the statute in regard to a license. As the law stands, no one is allowed to practise pharmacy without a license obtained after examination from the Board of Pharmacy. Hitherto this law has not been enforced as regards the dispensers of homœopathic remedies, though no satisfactory reason appears why they should have been exempt. One of the lawyers for the defendants, who pretends that it is great injustice to demand that his clients should be examined by allopathic druggists (whatever they may be), makes the astonishing assertion that the prosecution of this drug firm is simply "preliminary to an allopathic attack on homœopathic physicians."

The New Building of the New York Hospital.—Ground was broken some time ago for an addition to the New York Hospital, providing accommodations for the library and museum, and dormitories for the students in the training-school. The new building will be after plans by Mr. George B. Post, and will be fire-proof. It will front on Sixteenth Street, in the rear of the hospital, to which it will be similar architecturally. It will be built of pressed brick, with Nova Scotia stone trimmings, and will be seven stories high, one hundred feet deep, and thirty-five feet front. The basement will be one room, devoted to the pathological museum. The first and second floors will be for the library, one large room, with galleries, alcoves, etc. The remaining five floors will be dormitories for the nurses of the training-school. Each floor will accommodate twelve nurses. The rooms will be arranged in suites of three, two bed-rooms and a sitting-room in each suite. Two nurses will occupy each suite. On the roof will be a garden, probably enclosed in glass, where patients can enjoy the cool breezes that blow over the house-tops. Here there will be flowers, plants, an aquarium, seats, and hammocks. The new building will cost about $150,000, and will probably be ready for occupancy by October.

A Chance for a New Chair at Vassar.—Dr. E. Golay, a French physician, advocates a wider basis to the education of the fair sex. There is, he considers, one thing especially wanting in the tuition of the present day, and he is anxious that girls when at school should be instructed in the art of bringing up children, which, to his mind, is the most useful of all the subjects which they should learn.

An Osphresometer.—Dr. Zwaardemaker, of Utrecht, has devised an instrument for measuring the intensity of the olfactory sense. It consists of a bent tube which may be lengthened or shortened at will, one end of which contains the odoriferous substance. It has been found that the intensity of the odor varied indirectly with the length of the tube, and this principle has been taken advantage of to measure variations in the intensity of the sense of smell.

The Boyertown (Pa.) Medico-Chirurgical Association was organized on January 3d. It is composed of medical practitioners living in the adjoining sections of Berks and Montgomery counties, and its objects are stated to be "to promote harmony and good fellowship among its members, to discuss medical and surgical topics, and in general to elevate the standard of the medical profession." The officers of the new society are Drs. F. R. Brunner, President; De Long and Heffner, Vice-Presidents; Wertman, Secretary; Leidy, Corresponding Secretary; and Rhoads, Treasurer. The society will meet every four weeks about the period of full moon, on account of the members who have some distance to come.

Dutchess County Medical Society.—The annual meeting of the Dutchess County (N. Y.) Medical Society was held in the court-house, Poughkeepsie, on January 8th. A resolution was passed endorsing the principle of the Batcheller bill, which provided for the passage of a law compelling the removal of the indigent insane from the almshouses of the respective counties to the State institutions for the insane. There was some opposition to this resolution, on the ground that the State institutions were inadequate to care for all the insane, and that no mandatory law should be passed compelling the removal of the insane to State institutions until sufficient accommodations for their reception had been provided. The principle of the bill was, however, endorsed, the question of its present expediency being left out of consideration. The following officers were elected: President, Dr. Robert K. Tuthill; Vice-President, Dr. H. C. Wilbur, of Pine Plains; Secretary, Dr. William Cramer, of Poughkeepsie; Treasurer, Dr. Charles H. Langdon, of the Hudson River State Hospital. The attendance at the meeting was, for some unexplained reason, unusually small.

Stanley's Testimony to the Value of Vaccination.—In a recent letter received in London from Stanley, the explorer writes: "The small-pox broke out among the Manyena and their followers, and the mortality was terrible. Our Zanzibaris escaped this pest, however, owing to the vaccination they had undergone on board the Madura." Such evidence is, of course, not required by any sensible man, and will not be admitted by the anti-vaccinationist, who will invoke the favorite argument of the sceptic, that of coincidence. Nevertheless it is interesting.

The Hospital Saturday and Sunday Collection had received, up to January 16th, $31,740.48.

Prize Essay on Epilepsy.—Dr. H. A. Hare, of the University of Pennsylvania, has been awarded a prize of four thousand francs for an essay upon epilepsy by the Académie Royale de Médecine de Belgique.

A Presentment against Christian Scientists.—The Grand Jury of Onondaga County, N. Y., has made this presentment against Christian Scientists and Faith Cure Healers:

Whereas, It is notorious that in the city of Syracuse there are many persons engaged in the practice of medicine who have in no manner complied with the statutes of this State; and

Whereas, By such practice the health and welfare of our community is greatly imperilled; be it therefore

Resolved, That it is the opinion of the Grand Jury that the District Attorney of this county owes it as a duty to the people to request the aid of the medical societies of the city and county in searching out all such illegal practitioners, as the laws of the State provide.

There have been several deaths in Syracuse traceable to the neglect of proper medical attention consequent on belief in these irrational methods.

The Late Dr. Lewis Hall Sayre.—At the meeting of the Board of Governors of the Hackensack Hospital, held on January 7, 1890, the following resolutions were adopted and ordered to be placed on the minutes of the board:

Resolved, That the death of Dr. Lewis Hall Sayre, one of the consulting surgeons to this hospital, is deplored by us as a great calamity to this institution, and deprives us of a man possessed of fine surgical knowledge and skill.

Resolved, That the services of Dr. Sayre, always so freely and cheerfully rendered, have been of inestimable value to the medical staff and patients of our hospital, and can only be suitably estimated by One who said, "Inasmuch as ye have done it unto one of these, my brethren, ye have done it unto me."

Resolved, That to the family of the deceased we offer our heartfelt condolence, and assurance that the memory of his skill and generous kindness will be cherished by this board and passed on to our successors as a precious legacy.

DAVID TERHUNE,
ALVAH TROWBRIDGE,
DAVID ST. JOHN, M.D.,
Committee.

Obituary.

EDWARD LEICESTER PLUNKETT, M.D.,

NEW YORK.

DR. EDWARD LEICESTER PLUNKETT died at his residence, 147 West Sixty-first Street, on January 10th, of pneumonia complicated with acute gastritis, after an illness of one week. He was born at Pittsfield, Mass., on July 6, 1856. He attended the Graylock Institute, South Williamstown, and in the fall of 1877 entered Lafayette College at Easton, Pa. While in his first year at this institution, he had the misfortune to lose his eyesight by purulent conjunctivitis. After a year or two he commenced the study of medicine, entering the New York College of Physicians in the fall of 1880. All of his lessons were read to him, and aided by a remarkable memory and a keen logical sense, to which was added an indomitable perseverance, he graduated from that institution with honor in 1885.

It was Dr. Plunkett's ambition to undertake the study of physical diagnosis with a view to teaching the same, and he had made some progress in that direction. But various circumstances turned his attention to quizzing medical students, and he entered upon this work with his customary ardor. In it he attained conspicuous success, having had as many as thirty men in his class at one time.

His tall figure was a familiar sight to the frequenters of the College of Physicians and Surgeons during the last ten years, as he regularly attended each year all the lectures on the primary branches. He had a noble ambition to perfect himself in his chosen line of work, and had at the last the keen satisfaction of knowing that his ability was recognized and generally admitted.

Society Reports.

PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, December 6, 1889.

DR. FRANCIS P. KINNICUTT, PRESIDENT, IN THE CHAIR.

(Continued from p. 55.)

Discussion of Dr. Peabody's paper on the "Therapeutics of Typhoid Fever."

The Rational Treatment of Typhoid Fever.—DR. J. WEST ROOSEVELT said, that as one who most strongly believed in, and practised, the symptomatic or rational treatment, he dissented from the description of that method given by Dr. Peabody. The rational symptomatic treatment consisted in meeting individual symptoms, but not by methods which were persisted in after they had been shown to be injurious. Antiseptics, as now defined, did not form a part of rational treatment. Indeed, Dr. Peabody had called attention to the fact that beta naphthol was actively poisonous, at times producing albuminuria, etc. As a rational man, he disapproved of giving useless drugs, as gallic acid in hemorrhage; or so called antiseptics to disinfect that which they could not reach, as the typhoid poison; or using antipyretic measures of any kind, if tangible and immediate good did not follow.

In Brandt's statistics one suspicious circumstance was to be noted, namely, that a large number of the patients recovered very early. This fact threw doubt on the diagnosis. The statement that of a very large number of cases coming under treatment before the fifth day none died, was itself sufficient to cast doubt upon the figures.

Difficult to Make Diagnosis before the Fifth Day.—To make the diagnosis of typhoid fever before the fifth day was difficult, and the fact that such a patient recovered in a very short time would be taken in this country as a strong indication that the case was not one of typhoid fever. Yet a number of these patients seem to have recovered very soon. In this country we are not so loose in diagnosis. In Roosevelt Hospital, for instance, distinction is made between typical cases of typhoid fever and the cases of fever of an indefinite type which resemble typhoid and may or may not be typhoid. It seemed probable to him that in the study of statistics of the treatment of typhoid fever the death-rate had not varied much in the past forty or fifty years, just as it has not in pneumonia. Unfortunately, statistical tables sufficiently full to settle such a point are hard to find. We should not look at masses and forget individuals in treatment. The chances of an individual recovering from a given disease were to be estimated by symptoms. The chances which, estimated by statistics, gave a death-rate of ten per cent. in certain diseases, in individual cases are not one in ten at all.

As to Treatment by Antiseptics.—We had not proved that they reached the source of the disease, nor had we proof that they did good, while we did have proof that they sometimes did harm. In the case of the cold-water treatment he thought we could not at all speak so positively. He hardly thought any statistics yet published showed much for or against it. Here, too, in making up statistics it should be remembered that we classify our cases more severely than they do abroad. Comparison of American and foreign statistical records is hard and severe. Moreover, the terms typho-malarial and remittent are common, and destroy the value of our figures. He maintained that in the cold-water treatment the guide was simple; if cold applied was followed by good results, and not by bad, it might be repeated with advantage.

High Temperature not Necessarily Dangerous.—Nevertheless, if one had a patient whose temperature was high, say 105° or 106° F., and yet the general condition was good, it was important to remember that the temperature in itself was not necessarily an indication of danger. In making this statement he was sustained by the observations of a number of others. In such a case, with high fever and no other severe symptoms, the antipyretic measure is needless. In children we very frequently saw a high temperature which did not result in harm. In looking at the temperature as an indication, one could not apply one rule to the child and another to the adult if the fever be regarded from a physical basis. If a high temperature of itself injured the tissues, producing parenchymatous degenerations and violent symptoms which went with them, it should do it in a person of any age. If it did not so act in every case, then the high temperature by itself could not be regarded as of so great importance as some would have us believe.

The Phenomena and Causes of Increased Temperature.—Either the fever heat injured the tissues, or the heat was the direct product of increased tissue-change, or the increased temperature was not at all dangerous. If the first, cold should certainly prevent death, which it does not. If the second, as the production of heat-units seems unchanged by cold bathing, it hardly can be thought that the tissue-change is diminished. He did not wish to deny that both the cold pack and the cold bath were not extremely efficacious under certain conditions. Neither did he wish to deny that he had seen beneficial results from the use of antipyrin and other antipyretics. What he did wish to say was that we must find a better explanation of the benefit derived from the use of cold than the simple statement that increased heat-production and high temperature were deprived of their dangers by its application. Further, as concerned the rational treatment, it should be remembered that it implied one's taking into consideration the temperature, respiration, pulse, and general condition. Yet we had seen it stated in paper after paper that antipyrin, for instance, had lowered the temperature so and so, and that no harm had been done. The same was true of other antipyretic drugs which had come forward. But that was not the view to take of the matter. It was not a question of whether one could lower the temperature by this or that drug, but rather, whether the patient's condition was improved after such a result. It was that which he had in mind when speaking of the rational treatment; it was not the poisoning of the patient by gallic acid, or reducing the temperature below normal, whether by drugs or by external applications.

DR. BEVERLEY ROBINSON said he was disposed to agree with Dr. Roosevelt. But, as he understood the reasons given by the best observers for the use of the cold pack, cold affusion, or even the cold bath, they were not alone that it caused a reduction of the temperature. Even Brandt, he believed, attributed the benefit (in part, at least) to a stimulation of the nervous system, which resulted in reduction of the fever and improved circulation, nutrition, etc. An improvement in the patient's general condition was thus brought about which did not follow the use of antipyretic drugs, such as phenacetin, antipyrin, etc. In view of these facts, he was certainly of opinion that there was a rational use even of cold baths in the treatment of individual cases, and, in so far, he was in accord with Dr. Roosevelt. He thought it was the greatest possible mistake to bring these data from Germany and apply them to the United States. We should take patients as they were seen in America, and treat them judiciously and rationally. Personally, he had been opposed to the cold-bath treatment, not only of typhoid fever, but of high temperature in general in children and in others. For instance, in scarlet fever in children, he had seen instances in which the cold bath had produced bad results. In typhoid fever, however, with high temperature, it had seemed to him that it would be desirable to employ the cold pack or cold affusion, and he did not doubt that in some cases it was of real benefit; but there were others in which he was satisfied that it did harm, as was shown by the impaired circulation, cyanotic condition of the lips and extremities, and the bad pulse. He was

aware, however, that these symptoms were regarded by some authorities as, if not useful, at least not harmful. But he did not agree with them. He exhibited charts showing in detail the treatment and temperature-record of a case of typhoid fever treated in St. Luke's Hospital, and said that in some respects it corroborated the statements of Dr. Roosevelt regarding the rational treatment, which was pursued in this case.

The patient had entered his service November 8th, presumably on the thirteenth day of the disease. The temperature was persistently high throughout the disease, except when reduced by antipyretics. The means employed for controlling the temperature were antipyrin and cold sponging; antisepsis was also tried by means of thymol. On several occasions the temperature was 106° F., and often 105° F. Except for this, however, there was no other symptom which showed the gravity of the disease. In spite of the high temperature throughout, he did not believe the muscular tissues were unfavorably affected in any way, or, if they were, they did not show it. According to his observation, where there was so high a range of the temperature as in this instance there were almost invariably other severe symptoms or signs of a severe case; yet this was not in accord with the statements of some other observers, especially in foreign countries. They stated that parenchymatous changes in the viscera did not seem to be connected with high temperature; that those changes were present often where the temperature had shown a low range. It had also been stated that structural changes were the cause of the fatal result, and they had been searched for in the heart at autopsies in this city, but their presence as the usual cause of death had not been shown. From these facts he was led to suppose that the general nerve-depression was the main factor to be considered, and that it afforded the true explanation of the efficacy of the cold bath when judiciously used. He would also allude to the view, now more or less commonly accepted, that the ptomaïnes developed in the alimentary tract were probably a more important cause of the death-rate in typhoid fever than mere elevation of the temperature, and it was for this reason that one rationally employed intestinal antisepsis. Whether it was a good method or a bad method, he did not know. He simply used it because there seemed to be a basis for it, consisting in the fact that the fatal results came not from the temperature, but from the severity of the poison which produced the high temperature. Of course, the high temperature was a more or less dangerous phenomenon, against which it was proper intelligently to wage war, either by cold baths or other methods. He concluded with the remark that he was disposed to believe that the expectant plan of treatment was the proper one, and that there should be no absolute rule laid down for all cases.

Dr. C. L. Dana said he felt very heartily in sympathy with Dr. Peabody's views. Our results in the treatment of typhoid fever were not what they should be or could be, and he believed Dr. Peabody was working in the right direction in attempting to formulate something more than simply a symptomatic treatment. He had looked over the records of the cases which had been treated in their division of Bellevue Hospital the past year, and had found about twenty-four cases, of which number there were three deaths. In one case, however, the death occurred in a person who was practically dead when he entered the hospital, so that the mortality-rate would be about thirteen per cent. The treatment which he had attempted to carry out while on duty in the hospital, the past eight months, had been, as far as he had tried any positive treatment, the employment of intestinal antisepsis. It seemed to him that that was about the only direction, excepting the use of cold baths, in which we had found any rational indications. His experience had been, like Dr. Peabody's, that the cases in which this method had been tried did seem to run a milder course. Certainly, during the eight months of its trial there was scarcely a death. Still, he had never felt satisfied that the antiseptic treatment was very efficient, and lately it had not been carried out very thoroughly. The present treatment which they employed was, therefore, largely a symptomatic one. He had read some of the articles on the cold-water treatment, and, although much prejudiced against it at first, yet it seemed in that direction there was hope of greater advancement. He thought a good deal of Dr. Roosevelt's part of the discussion bore on obsolete issues. Dr. Robinson had already stated that the object of the cold bath was not so much to reduce the temperature as to stimulate the nervous system. But he thought another point in Dr. Roosevelt's remarks might be criticised; he had said, if he understood him correctly, that the cold bath did not lessen heat production. Dr. Dana believed the contrary—that in abstracting heat it eventually lessened its production, and therefore, the antipyretic measure in itself was a rational one. It seemed to him that Dr. Peabody's substitute for the cold bath, the cold pack, etc., would not be really a substitute, for these antipyretics did not stimulate the nervous system, but had rather the contrary effect.

Temperature in Typhoid Fever.—Dr. A. H. Smith thought that underlying the subject was the question, what was the relation of the temperature of typhoid fever to the essentially diseased condition of the patient? There was a relation of cause and effect, but which was cause, and which effect? It must be assumed that the original poison preceded the rise of the temperature, therefore that the essential disease preceded the temperature. Was there a causal relation in the other direction? Could a high temperature aggravate in any way the action of the poison, or increase its production? Did the fact that the body having several degrees more of temperature, facilitate in any way the production of poisonous material? If it did not, then it would seem that to attack the temperature itself was an entirely erroneous method of treatment. If, on the other hand, it could be shown that a higher temperature did increase the production of ptomaïnes, or any other intoxicating principle, we must attack the temperature as a cause. It appeared to him that we had two classes of poisons to deal with in typhoid fever: (1) the original poison, perhaps beginning with the action of bacilli producing ptomaïnes, or something of that kind, and then perhaps (2) simple sepsis, as a result of decomposition going on in material contained in the intestinal canal, a poison which might arise entirely independently of the original cause of the disease, when favorable conditions were present. He had repeatedly noticed, when the bedclothes were turned down to examine a patient suffering from typhoid fever, a peculiar odor which advised him at once that the stools were in a highly putrid condition. He had almost invariably found that condition of the stools associated with a high temperature, and when the colon was thoroughly washed out the temperature would immediately fall. That was an experience which probably all had had, and it had already been brought forward by others. It would seem to indicate that the reabsorption of material contained in the intestine, entirely independent of the original typhoid poison, caused an elevation of the temperature and vital depression, and pointed to the importance of intestinal antisepsis as far as it could be carried out. So far, at least, as the bowel was accessible from the anus, he thought we should give it a good deal of attention, especially where we found a putrid condition of the discharges. He had used creoline, and had found it benefited the patient materially. Whether we could trace the bacillus into all its recesses, and prevent the formation of the poison, was still an open question.

As to the temperature being an indication of the amount of mischief going on in the system, he did not believe it was a reliable one. He had repeatedly seen cases terminate fatally in which the temperature was moderate throughout. Whether much absorption took place here through the ulcers in the intestine, producing a condition similar to what was seen in the septic absorption by wounds, was another question. He recently had a case

which illustrated both these ideas. Until the last two or three days the temperature scarcely rose above 103° F., there was great enlargement of the liver, extreme tenderness in that region, oscillations of temperature, and evidence of that kind of infection seen in surgical cases. The patient died, and the autopsy showed about eleven feet of the intestine, measuring upward from the ileo-cæcal valve, greatly ulcerated, though not perforated. It seemed that within a few hours, since the marked elevation of the temperature, the intestine had become almost uniformly ulcerated that distance. On the other hand, he had seen cases with a high temperature throughout, yet, if it were not for the thermometer, one would not have known that the patient was very sick. He thought the cold bath and other antipyretic measures often produced benefit, not only in reducing the temperature but in allaying nervous symptoms. A dose of antipyrin, for instance, would frequently change the whole aspect of the case. He believed the wear and tear was lessened by the conservative use of these agents. With regard to the method of applying cold, he had been very much pleased by simply laying a wet towel, for example, over the anterior portion of the body, relying upon evaporation to reduce the temperature, rather than upon the low temperature of the water used. Cold sponging had been employed in his service recently, very considerably, generally with a reduction of the temperature by one or two degrees after each sponging. Recently he had employed antipyretic drugs very sparingly. Regarding statistics, he thought the ambulance service was a very disturbing element. Any hospital with an ambulance would be constantly receiving patients sent there by doctors outside who had given them up to die.

Replying to questions by Dr. Robinson, he said the bowel should be washed out both in diarrhœal and constipated cases, and that he had not seen the practice induce hemorrhage.

Cold Baths.—Dr. Roosevelt did not wish it to be understood that he objected to the use of cold baths. He did, however, claim that elevation of the temperature by itself was not an indication of danger, and that it was not always an indication for the use of the cold bath. And with regard to intestinal antisepsis, he believed it was possible to disinfect the stools to a certain extent by antiseptics given by the mouth, but he did not think it was rational to suppose one would in this way kill the bacteria in the mesenteries, lymphatics, etc.

The President thought that, in the United States, opinions upon the results of Brandt's method of treatment could *only* be formed through statistics, as, except in a few isolated cases, so far as he knew, it had not even been attempted. We were, however, very familiar with the expectant plan of treatment, and the mortality-rate of typhoid fever so treated was very high. A study of Brandt's statistics should lead, he thought, to one effort on the part of hospital physicians to give a thorough trial to a method of treatment which had been followed, apparently, by brilliant results. Personally, he had long wished to practically test it, and had only been prevented through the lack of a sufficiently large nursing-staff. He was quite in accord with the views expressed by Dr. Smith in regard to the efficiency of intestinal antisepsis. Such treatment had its own sphere of usefulness in typhoid fever, but not, he thought, in the form of destroying the specific poison of the disease. He would suggest a possible explanation of the fact mentioned by Dr. Peabody (viz., the failure of Erlich's test to respond during the use of intestinal antiseptics), in a chemical interference with the reaction, through the presence of such drugs in the urine in their elimination by the kidneys.

He desired to call earnest attention to a very practical point, and that was the necessity of a more thorough disinfection of typhoid as well as other infectious stools than was commonly practised.

Uppelmann had very recently published the results of a series of experiments bearing upon this point. He subjected typhoid, cholera, and dysentery stools, which previously had been demonstrated to contain the specific bacilli of these diseases, to the action of various antiseptics, viz., solutions of sulphuric acid, hydrochloric acid, acidulated corrosive sublimate (corrosive sublimate, two parts, hydrochloric acid, one-half part, water, one thousand parts); five per cent. carbolic acid, caustic lime, potash lye, thirty-five per cent., slaked lime, creolin, about fourteen per cent., and finally boiling water. After varying intervals, their influence upon the bacilli was determined. Solutions of equal parts of sulphuric acid and water, of hydrochloric acid and water of similar strength, and of acidulated corrosive sublimate, were found to be by far the most effective. Eberth's bacilli were found after subjection of typhoid stools to a five per cent. carbolic acid solution for one hour, and the creolin solution was demonstrated to be even less effective. The unacidulated corrosive sublimate solution was markedly less effective than the acidulated.

The conclusions were, that even when treated with the most potent disinfectants, typhoid fever dejections could not be considered innocuous, unless subjected to their influence from a quarter to a half hour. Demonstrations as regards the length of time necessary for thorough disinfection had hitherto been lacking.

Dr. Peabody said he had been much instructed by the discussion, more especially since much of it did not bear at all on his paper; that he had made no point whatever with regard to the danger of fever as such, or as to the necessity of employing the cold pack to prevent patients from having a temperature of 106° F. He had merely spoken of the desirability of giving the cold baths or packs with a view of never allowing the temperature to rise, because he, for one, was open to conviction by statistics. He could not understand the position of those adverse to antipyretic treatment, except as explained by the fact that they were not open to conviction by statistics. The Brandt method had been tried a great many years in Germany. Brandt himself had collected over nineteen thousand cases, and of this number a large percentage came under treatment late in the disease; nor did they have a fair chance at the treatment, since it was carried out by persons who had not themselves faith in it, and consequently often did not apply it as it should be applied. Yet the mortality in this number was under eight per cent.

Brandt had collected another series of five thousand cases in which the method had been carried out by those who had faith in it, and here the mortality had been under four per cent. The speaker thought it ill became us, even if we were native Americans, and our patients were of American birth—although he must admit that many of his, or their parents, were foreign born—to disbelieve that a method which gave a mortality of less than four per cent. possessed no advantages over the fatal absence of method which prevailed here.

Whether the bacilli in the intestine were destroyed by antiseptics was a question which had not occurred to him at all. He had simply tried the antiseptics with a view of producing as nearly as possible an aseptic condition in the intestinal canal, and it seemed to him that to a certain extent that could be done. It might be that the antiseptics did get down to the chief lesion; it might be they did not. It might be that the results were merely a coincidence. It might be that they made the site of chief lesion a less desirable breeding-place for the typhoid bacilli. He did not believe for a moment that they chased the bacilli up to every hiding-place in the spleen and elsewhere.

As to the effect of cold sponging in reducing the temperature, he had almost uniformly failed of any satisfactory effects from it. He had tried it in three hospitals, under three different sets of nurses, and over a period of ten years, but he had not usually succeeded in causing anything like a *material* reduction of the temperature by it. It did cause it to fall occasionally, but as a rule it did not materially diminish it.

The Ambulance System.—As to the ambulance system, it was a disturbing factor here which they had not in Ger-

many. There was no question in his mind that the average case reached the German hospitals for treatment in a better condition than those which entered the New York hospitals. Brandt's method was in pretty general use in the German army at present. It had been tried thoroughly only in the second corps, and the difference in the rate of mortality between that corps and other corps of the army was marked.

Dr. Roosevelt: What is the proportion of cases of typhoid fever in each instance?

Dr. Peabody: I have not had access to the figures. They are not quoted in Professor Wood's book. But it is stated very explicitly that the mortality-rate was very much lower in the second army corps than in any other, and there is no reason to suppose, *a priori*, that there was a smaller number of cases in one than in the other in proportion to the number of men.

Even those gentlemen who object to the antipyretic treatment, or any systematic treatment, and advocate what they call the rational, or what I call the irrational, symptomatic treatment, tell us that "in appropriate cases" they believe in giving baths; that in "appropriate cases" they believe in giving antipyretic drugs. Will they not tell us what constitutes appropriate cases? I claim that the *average case* is an appropriate case for the cold bath, if given early enough. It seems to me the time has come when, in dealing with this disease in large numbers, you have to formulate your ideas and say what is the desirable thing to do in the average case; for there is no question that there is an average case, cases of average severity, which will stand about a given amount of antipyretic treatment, and will require about a given amount of stimulants per diem. It seems to me that to leave it in this vague way, and say that *in appropriate cases* they would do so and so, is simply to say that they themselves, from their own point of view, are solely to judge when these certain kinds of treatment are to be considered justifiable, and that usually the antipyretic plan is not to be followed.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 9, 1889.

William P. Northrup, M.D., President, in the Chair.

Hemorrhage in the Right Ventricle.—Dr. Eugene Hodenpyl presented a specimen showing "Hemorrhage into the Right Ventricle." The brain was removed from the body of a middle-aged man, who fell while walking in the street, and by the time the ambulance reached him he was unconscious. At the autopsy the speaker found a blood-clot in the right lateral ventricle, while the left lateral and the third and fourth ventricles were distended with a bloody fluid. The blood-vessels at the base of the brain were normal, and there was neither heart nor kidney disease.

Calcification of the Mitral Valve.—A second specimen shown was one of "Calcification of the Mitral Valve." The heart was removed from the body of a young man who had been in hospital under treatment for cardiac disease. He died suddenly, and at the autopsy, in addition to adherent pericardium, there was found an enormous calcification of the mitral valve, occasioning very marked stenosis.

Carcinoma of Male Mamma.—A third specimen was presented, of "Carcinoma of the Male Mamma." The tumor was removed by Dr. Hartley, from a man seventy-three years of age, who had noticed the presence of the growth for several years. The axillary glands were also removed. The tumor was about one-half by two inches in size. The patient made a good recovery, and is well at the present time. The axillary glands showed no lesions except hyperplasia.

Dr. Prudden asked if there was anything peculiar in the structure of the new-growth last presented.

Dr. Hodenpyl said that there was not. It was an ordinary alveolar carcinoma.

The President asked whether there was any history in the case of valvular disease. The stenosis was so great that one would suppose the symptoms must have been very marked.

Dr. Hodenpyl replied that the presence of a mitral lesion had been diagnosticated, but the history contained nothing of special interest.

Improvements in Accessory Apparatus.—Dr. G. C. Freeborn demonstrated some "Improvements in Accessory Apparatus." The first was a modification by Arnold of the clamp in Thomas' microtome, as a result of which the level of the specimen could be adjusted with much greater accuracy.

The second was an iris diaphragm for use with the Abbé condenser. By means of this diaphragm the amount of light admitted could be regulated with the greatest ease by simply turning a milled head, and it could be very gradually increased or diminished, instead of being changed suddenly as in the old style of diaphragms with a series of holes.

Dr. Prudden remarked that the special advantage of the diaphragm was that it was all in nearly the same plane, and it was on this account much better than the ordinary conical iris diaphragm.

Dr. Messenger asked whether the improvement could be applied to any microscope having an Abbé condenser.

Dr. Freeborn said that it could, with some slight modifications, be attached to any instrument. In reply to a question as to its durability, he said that he had had the diaphragm a short time only and could not therefore say how long it would last.

Dr. J. S. Ely said that he had had one in use for a considerable time, and he thought that with care it was very durable.

Dr. H. M. Biggs presented a microscope slide showing "Weigert's New Stain for Neuroglia Tissue." The formula, he understood, had been published very recently, but he had not seen the details of the preparation of the stain.

Encysted Trichinæ.—Dr. Frank Ferguson presented a microscope slide showing "Encysted Trichinæ." A boy, aged six years, was taken to the Long Island College Hospital, four years ago, for the treatment of a lump in the lumbar region. Incision revealed only muscular and fibrous tissues. A small fragment was taken from the edge of the wound and examined microscopically when numerous trichinæ were seen in each section. Each parasite was rolled up within a hyaline capsule. The muscular tissue was generally destroyed, and replaced by fibrous tissue rich in inflammatory corpuscles. The boy was taken away from the hospital, by his parents, before any history could be obtained.

Echinococcus Cyst of Liver.—Another microscope slide showed an "Echinococcus Cyst of the Liver." The entire cyst had been excised, and the section showed vast numbers of echinococci and hooklets. The tissue adjacent to the cyst was inflamed.

Hypertrophic Cirrhosis of Liver.—Dr. Ferguson then presented specimens showing hypertrophic cirrhosis of the liver, and chronic diffuse nephritis, removed from the body of a man, thirty-eight years of age, a merchant by occupation, and addicted to the rather free use of alcoholic liquors. He had had rheumatism twelve years ago, but gave no history of syphilitic or malarial infection. Three weeks before admission to hospital he noticed that his skin was growing yellow, and he suffered from anorexia and nausea. He complained of constant thirst, but had no pain and no itching although the jaundice became very pronounced. The area of hepatic dulness was very greatly enlarged, extending vertically from the fifth rib to within one inch of the anterior superior spine of the ilium, and laterally almost to the umbilicus. The urine was red in color, but clear, alkaline, sp. gr. 1.012, contained a trace of albumin, hyaline casts, and much bile

pigment. He died in about two weeks after admission to the hospital, the liver having in the meanwhile decreased about two inches in its vertical diameter.

At the autopsy the liver was found to weigh 3,800 grammes, was deeply bile-stained, and contained a large amount of new fibrous tissue. The kidneys were enlarged, with indistinct markings; the pyramids were of a green color, while the cortex was yellowish. The spleen was enlarged, measuring $10\frac{1}{2} \times 6 \times 2\frac{1}{2}$ inches, was dark in color and firm in consistency, and scattered throughout its substance were numerous small nodules with cheesy centres. The common bile-duct was filled with mucus, and to this fact the speaker was inclined to attribute the very marked jaundice present.

The Society then went into executive session.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

DISCUSSION AT THE MEDICAL SOCIETY OF LONDON ON THE DIAGNOSIS AND TREATMENT OF ANEURISM OF THE AORTA.

LONDON, December 21, 1889.

An important discussion on the subject of aortic aneurism commenced last week at the Medical Society of London, and has occupied the last two meetings of the society. The subject was introduced at the society's meeting, on Monday week, by Dr. Douglas Powell. He observed that, although the anatomical description of aneurism still included the fusiform and sacculated varieties, yet, clinically, all the features of aortic aneurism were grouped about the sacculated form, and, in regard to clinical signs and treatment, the fusiform variety merged into the form of heart disease, with which it was associated, and to treat it seriously as aneurism was to damage the prospects of the patient. The essential phenomena of the (clinically) true or sacculated aneurism were: 1, those of pressure-tumor signs; 2, those indicative that the tumor was a vessel tumor—a diverticulum from the vessel. To attach primary importance to the signs of arterial disease or disturbance without sufficient inquiry for those of tumor, was to invite error in diagnosis. A systolic murmur, when heard over a localized area remote from the heart, was of value in diagnosis, but in about half the cases of aneurism which presented themselves no murmur was present, and in some of the remainder the murmur heard was by no means the most important sign present. A diastolic murmur was of great diagnostic value, for it supplied distinct evidence of intra-arterial disease, and if it were associated with the pressure signs of tumor the aneurismal nature of that tumor was almost demonstrated. Thrill was a rare sign in true aneurism—a common one in spurious aneurism and in simple dilatation of the aorta. Dr. Powell remarked that the pressure signs of aneurism (as affecting the parietes, viscera, nerves, air-tubes, œsophagus, and vessels) were common to aneurismal and other tumors, but aneurismal pressure symptoms exhibited more inconstancy than those of solid growths. Among other diagnostic signs he would especially mention a systolic jog often appreciable to the ear through the medium of a rigid stethoscope, and, what was of greater importance, the diastolic shock sound in many cases could be similarly appreciated, and when well marked was absolutely diagnostic of aneurism. The laryngoscope aided in diagnosis, but the sphygmograph was of little use except as a recording instrument. Tufnell's method of treatment was of value when it could be carried out well, and especially in cases of abdominal aneurism and of sacs pressing deeply upon vital parts; also in congested aneurism when a venesection might sometimes be employed first with advantage. He condemned the wire and galvano-puncture treatment of aneurism as causing clotting of the wrong sort and in the wrong place, that is, in the centre rather than from the circumference of the aneurism; in certain cases, however, severe symptoms had been relieved by them. Possibly, in external sacs, Wooldridge's extract of lecithin might (with great caution) be injected. In conclusion he proposed the following questions, viz.: 1. Was fusiform aneurism to be regarded and clinically treated as aneurism? 2. What was the relative importance of pressure signs and auscultatory phenomena in the diagnosis of aneurism? 3. What was the diagnostic value of the diastolic "shock" sound? 4. Was it only heard in aortic cases affecting the arch? 5. Should the Tufnell treatment be employed continuously or intermittently? 6. Should iodide of potassium be given in association with the Tufnell treatment? 7. Was any information forthcoming as to the value of the fatty diet in aneurism? 8. What prospect was there of utilizing the coagulating powers of lecithin? 9. What was the value of ligature in the treatment of thoracic aneurism? 10. What was the value of the galvano-puncture and iron-wire treatment?

Dr. Broadbent said that he agreed with Dr. Powell that pressure signs were more important in diagnostic purposes, with this qualification, that the pressure signs depended very much upon the situation of the aneurism. Even a large aneurism of the ascending aorta might produce but little pressure upon neighboring parts, owing to its natural mobility. He sometimes alluded to this form as the aneurism of physical signs, while aneurism of the arch proper, or of the descending part, was rather an aneurism of symptoms. A murmur was rather the exception than the rule. One of the most valuable signs was the diastolic shock, either audible or perceptible to the hand. Fusiform aneurism was not amenable to any treatment, though we might lower the intra-arterial pressure and enjoin rest if otherwise necessary, though not with the idea of promoting a cure. In the other form of aneurism his experience with iodide of potassium was that it produced striking effects in promoting consolidation within the sac. He believed that it acted virtually in the same way as the Tufnell treatment, viz., by draining off the fluid by the kidney and so inspissating the blood. The condition of the patient would not, as a rule, permit of large doses of iodide being given while carrying out the Tufnell treatment. Iodide did most good in cases where there was a large sac with a small mouth. He concurred with Dr. Powell's views as to the use of iron wire. He related a case of left subclavian aneurism in which consolidation had been twice effected by means of galvano-puncture, but on both occasions the clot subsequently broke down; the aneurism was ultimately cured by applying a shot-bag. He only resorted to bleeding when there was pain, but the relief was then very striking. Dr. Sibson's plan of treatment by ergot unquestionably lessened the size of the tumor; this was not due to any specific action on muscular fibre in the sac-walls, since he had never been able to discover any there.

Dr. Ord said that in a certain number of cases of aneurism of the thoracic aorta, the first indications were from the circulation, and he insisted on the diagnostic value of local signs, such as pulsation, murmur, thrill, shock, dulness, undue pulsation, etc.; pressure symptoms completed the diagnosis. There was a liability to error in cases where the lung was withdrawn from the front of the vessels, giving rise to pulsation and thrill; also in cases where a tumor intervened between the aorta and chest-wall. He thought the diastolic shock could be heard as well with a flexible as with a solid stethoscope. The diagnosis of abdominal aneurism was often very difficult. With reference to treatment, he had found Tufnell's method very beneficial, but he generally associated it with iodide of potassium, whether there was a history of syphilis or not. He confirmed what Dr. Broadbent had said as to the ergot treatment, and especially called attention to the relief obtained in cases exhibiting pressure symptoms by the administration of ergot. He did not think galvano puncture necessarily gave rise to consolidation *en masse*.

Dr. Bristowe remarked that he was himself somewhat of a pessimist as to treatment, as he thought that drugs afforded at most a passing relief. Post-mortem experience seemed to point to the fact that the permanently cured cases, that was, those in which the sac was thoroughly filled with clot, were cases in which aneurism had not been suspected during life, and in which the patient had been bedridden and dying for weeks from something else. He admitted that this was rather in favor of the Tufnell treatment, since the effect was to bring about a similar condition. He had no faith in treatment by wire, by galvano-puncture, or by iodide of potassium. Patients with aneurism were benefited by rest, diet, and generally by measures which reduced the intra-arterial blood-pressure; but he thought it was open to question whether it was worth while rendering these patients useless members of society for the sake of a problematical prolongation of life for a few weeks or months. He thought it was, on the whole, preferable to allow them to carry on their usual avocations, even if they died a little sooner, though this did not necessarily follow. He alluded to the cases of Dr. Murchison and Dr. Hilton Fagge, both of whom, though they suspected they were suffering from aneurism, continued to work till the last. A patient of his own had continued at work for the last three years, with occasional treatment when the symptoms were severe, and he urged that the patients were happier thus than if kept in bed all the time.

The debate was resumed at the last meeting of the society and brought to a conclusion. In resuming the discussion, the President (Dr. Theodore Williams) congratulated Dr. Powell on the practical character of his propositions, and especially on his attaching more importance to the pressure phenomena than to the cardio-vascular signs in the diagnosis of aneurism. He remarked that fusiform and saccular aneurisms sometimes coexisted in the same patient. He had never heard the diastolic shock sound, except in cases of aortic aneurism, but it was not always to be detected in these. Murmurs were as often absent as present. The relative importance of auscultatory phenomena and pressure signs depended principally on the portion of the arch involved. Aneurism of the first portion of the arch usually presented some physical signs in the shape of pulsation, dulness, shock, and murmur, and it was generally with this form that cases of aortic regurgitant disease with retracted lung were confused. He thought, however, that the position of the heart, the presence or absence of cardiac hypertrophy, and the results of measuring the two sides of the chest, were generally distinguishing features. In many cases of aneurism of the transverse and descending portions of the arch the evidence of auscultation was often wanting, and that of pressure signs most important, and the variations of pressure from changes in the size of the vascular swelling often proved of assistance in the diagnosis. Dr. Williams referred to a case of lympho-sarcomatous tumor in the mediastinum which gave rise to symptoms similar to those of aneurism, and also to a case in which enlarged syphilitic glands produced similar symptoms. He observed that the presence of markedly tubular breathing above one or both scapulæ was one of the most valuable signs in obscure cases, but no sign or symptom could be absolutely relied on. He had obtained excellent results from the iodide of potassium treatment, while restricting the patient's liquids, and limiting his exertions (without keeping him in bed) by confining him to one floor. He thought this was sufficient for most cases of aneurism, but consolidation sometimes took place under very opposite conditions, as he had witnessed in the case of a shoemaker suffering from aneurism of the ascending aorta (apparently pointing in the second right space), but in whom the tumor consolidated sufficiently to withstand a blow from the hand of the patient, though the latter had continued to pursue his heavy labors at the last.

Dr. Quain recalled the case of Liston, the diagnosis of whose case had baffled the most eminent authorities of his time. With regard to treatment, he could recall many cases in which iodide had saved life, or at least rendered it tolerable. It was important to notice even slight symptoms, and he alluded to a case in which the presence of very slight stridor had alone saved him from giving an unguardedly favorable prognosis in the case of a man who died shortly afterward from rupture of an aortic aneurism.

Dr. Semon urged the importance of making a laryngoscopic examination in every case of suspected aneurism, and (referring to his theory that the adductors of the cords had a proclivity to become involved in functional affections, while the abductors were more likely to be affected in cases of progressive organic disease) maintained that the discovery of the paralysis of an abductor was of the utmost importance to the diagnosis.

Dr. De Havilland Hall mentioned cases showing the difficulty of distinguishing between pulsating empyema and aneurism, and insisted upon the diagnostic importance of the steady downward progress in malignant growth simulating aneurism, the progress in cases of aneurism being more fluctuating. He preferred aconite to digitalis when a cardiac depressant was indicated.

Dr. Mitchell Bruce urged a thorough and systematic examination of every patient suspected of aneurism, especially by means of the simpler methods of physical examination, and said that the neglect to observe the patient closely before passing on to auscultation was one of the reasons for the affection escaping notice.

Dr. Kingston Fowler said he associated a diastolic murmur rather with aortic regurgitation than with aneurism. He thought that one cause of aneurism being overlooked was, that sufficient importance was not attached to the symptom pain. He was of opinion that the prognosis —so far as duration of life was concerned—was not so unfavorable as it was generally supposed to be.

Dr. Seymour Taylor pointed out that in small aneurisms death most frequently resulted from bursting, whereas in large aneurisms the cause of death was pressure.

Drs. Maguire and Ewart gave the history of some cases exhibited by them.

Dr. Douglas Powell then replied, and explained that, with regard to fusiform aneurism, he did not mean that it called for no treatment, but that its treatment was not that of aneurism proper. He agreed as to the necessity of a careful choice of the cases to be submitted to the Tufnell treatment. He was sceptical as to the use of ergot, and said twenty-minim doses were not likely to have much effect on the circulation. A certain proportion of cases would be unsuccessful, whatever was done.

ANTISEPTICS AND THE COUNTRY DOCTOR.

To the Editor of the Medical Record.

Sir: In the issue of your valuable publication of December 28, 1889, appears a correspondence from Dr. F. W. Van Dyke, of Grant's Pass, Ore., in which is predicated a vast amount of knowledge based upon a limited individual experience. His personal experience in the use of antiseptic measures is sufficient evidence to him that the leading minds of the profession are chasing phantoms; that the most advanced teachers and surgeons of our large cities are following a "popular craze," the most "trivial operations being made occult and mysterious and burdened down by elaborate antisepsis."

It would seem necessary to offer an apology for asking valuable space in the Record in which to reply to such statements. In denouncing antiseptics as valueless, and even dangerous and harmful, he would have it understood that he is voicing the sentiments of country doctors in general, which should not go unchallenged.

It seems strange that one who has been a "constant reader of the Medical Record for over thirteen years," should not have learned from it that surgery has been

revolutionized within that time by antiseptics. He confesses to have found much in the RECORD "well calculated to amuse if not to instruct the country practitioner," and the inference is that he has been more amused than instructed during the last thirteen years.

In obstetrics we are told that the "great guns of the profession in cities harass and torture their patients with antiseptic injections, antiseptic pads, etc." The curette is unqualifiedly condemned as an instrument of "great danger"—death not being unheard of following its use.

Possibly those of us who use the douche, and exercise strict antiseptic precautions, might have the same success without them that the doctor claims for himself; but if a case of puerperal sepsis were to develop in a case where we had neglected these precautions, I am sure we would feel responsible for the result. Not every woman delivered in pre-antiseptic times had puerperal fever, neither would they now if all precautions were abandoned; but if figures do not lie, there is much less of it since the introduction of antiseptics. If the doctor is willing to believe that the "great guns" in the large cities are not wholly given to misrepresenting and rendering facts "occult and mysterious," perhaps the statistical showing of maternity hospitals, before and since the advent of antiseptics, would prove instructive reading.

As to the use of the curette, modern men who are capable of using it as it should be used, and who have seen the immediate beneficial results follow its use that could have been obtained in no other way, will hardly be frightened by the doctor's warning. They know that about the only danger attending its skilful use is the danger of infection.

Of general surgery he says: "Who shall ever know the number of victims that have been slain in the large cities, in hospital and private practice, on the altar of this Moloch of antisepsis." . . . . "In surgery I have never had reason to feel dissatisfied with my results." It is indeed difficult to account for such a statement from one who has been a constant reader of the leading medical journal of the country for thirteen years, in which have been recorded the giant strides of modern surgery! I wish the doctor would inform us just how, where, and by whom this great human sacrifice is being made. A glance at the hospital records again will dispel this delusion at once.

In his breast extirpations, amputations, etc., he sometimes used antiseptic solutions and sometimes simply hot water, and is compelled to say that he could see no difference in the results. I am prepared to believe this: I once knew a reputable practitioner to purchase some antiseptic gauze. Without attending to the necessary details, he used the gauze in dressing wounds, and then, because suppuration followed, he condemned the whole thing as nonsense. Hot water may be aseptic, and if a wound is aseptic and can be *kept so*, the results will equal those of the typical antiseptic dressing. The use of the antiseptic dressing is to keep the wound aseptic. Solutions and dressings are only a part of the programme, and while there is nothing "occult or mysterious" about it, it certainly does require great care, skill, and experience to obtain ideal results. Morris ("How We Treat Wounds To-day") says, the man who clears a stream at a bound is in a very different attitude from the man who jumps *almost over it*. To practise modern surgery successfully one must master the principles and then carry them out religiously.

Now, I would like to ask Dr. Van Dyke, candidly, how many times he has obtained primary union after amputation of an extremity? I would like to know if, when operating, he does so with a rational expectation of definite results?

Believers in antiseptics do, and if they fail, know where to look for the cause.

One of the most striking examples of the difference between the old and the new surgery is afforded in cases of osteo-myelitis. By the old method, the diseased bone and marrow are removed and the great cavity left to fill in by granulation, taking many months, often, for its accomplishment. The modern surgeon, by exercising great care and skill, may, by utilizing Schade's method or Senn's implantation of aseptic bone-chips, accomplish a better result in a few weeks. Here he must clear the stream at a bound, or walk around it the old-fashioned way, as there is absolutely no half-way ground.

In the face of these brilliant achievements, and many others that go to make modern surgery what it is, the man who lifts his voice against it must expect to be classed as a "back number." I will say, in closing, that it is indeed refreshing to see an article against antiseptics in which the Lawson Tait "chestnut" is not offered as a "clincher." Respectfully,

C. W. OVIATT, M.D.

OSHKOSH, WIS., January 5, 1890.

MEDICAL CIVIL SERVICE EXAMINATIONS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: I do not believe that any controversy between Dr. Robert H. M. Dawbarn and myself will be of any interest either to yourself or the readers of your journal. Dr. Dawbarn's grievance as to his candidacy some years ago for a medical position has no interest for me, and his strictures upon the methods of conducting Civil Service examinations, being simply his opinions as against those of gentlemen who have given much time and thought to these matters, and whose reputation, character, and knowledge are unimpeachable, are not much more interesting.

But Dr. Dawbarn's charge that a candidate came to this office and procured a set of questions, took them home, and answered them there at his leisure, being a plain and palpable violation of law, if true, deserves the fullest punishment of the law.

This charge, it appears, is made by Dr. Dawbarn, not upon any knowledge he has upon the subject, but upon the mere say-so of a candidate who is now in Europe. When he returns, Dr. Dawbarn may depend upon it that the charge will be proved or retracted.

I have been connected with the Civil Service of this city since the first day of April, 1889. I have endeavored to treat every candidate, whether professional or lay, with courtesy and fairness, and I would be glad to hear of any case since that time where any candidate has been dealt with in any other way.

The editor of THE MEDICAL RECORD, or any physician, will be welcome to any examination of the system, working, and records of this office at any time, whether he may have a grievance or not.

Respectfully,

G. K. ACKERMAN,
Secretary.

NEW YORK CITY CIVIL SERVICE BOARDS, COOPER UNION,
NEW YORK, January 13, 1890.

PROFESSOR M. ALLEN STARR AND REFLEX NEUROSES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: I find in your issue of January 4th an interesting article by Professor M. Allen Starr, on "The Relation Between Peripheral Irritation and Nervous Phenomena, with Special Reference to Eye-strain," and no doubt all of your readers have perused it with unusual care, because the subject of eye-strain has recently furnished the material for an uncommon discussion. Those of us who have had no special training in neurology, naturally turn for information to the writings of those who have made a special study of that branch of medicine; so I have turned to this communication of Dr. Starr in the hope that I might obtain a better insight into the relation between peripheral irritation and nervous phenomena, but

I confess to some confusion of thought after reading Section 5, which you will permit me to quote.

"5. Are such nervous manifestations characteristic? It has been a matter of dispute whether so-called reflex disturbances are identical with serious nervous diseases—such, for example, as hysteria, chorea, and epilepsy. When any one of these three diseases is studied, it becomes evident that a very wide difference is observed in the symptoms of patients suffering from the same affections. The varieties of epileptic attacks are innumerable. The distribution and severity of choreic movements is very various. The forms of hysteria cannot be recorded. To affirm, therefore, that nervous manifestations do or do not belong to one or the other of these diseases by studying the phenomena alone would be impossible. But each of these diseases in turn has a typical course and a general character. And it seems to me that in their course—in their mode and period of appearance, in the frequency of the occurrence of symptoms, in the variation in relation to influences acting upon the patient—the nervous manifestations arising from peripheral irritation are characteristic. So that they need not be identified with the symptoms of these diseases.

"I have already alluded to the difference between true insanity, true epilepsy, and reflex neuroses. In regard to chorea, it seems to me that in true chorea the onset of the motions is more rapid, their situation more definite (general or unilateral, rarely local), the history of infection or fright more decided, and the accompanying anæmia and cardiac complications more uniform than in any of the forms of reflex neurosis which simulate it. It is also natural to believe that reflex cases readily become chronic unless the cause is removed, and do not yield to arsenical treatment, while in true chorea the influence of this treatment is usually evident by the time physiological effects are produced, and relapses rather than chronicity are the rule. Out of 120 cases of chorea of which I have records, but 4 have been unaffected by arsenic and have become chronic.

"It seems to me, therefore, that the nervous manifestations arising from peripheral irritation, when carefully studied, differ from ordinary neuroses in their history and therefore present features which are characteristic. Reflex neuroses should therefore not be called epilepsy and chorea, even though they may resemble these diseases."

1. From this are we to understand that reflex neuroses, epilepsy and chorea, are distinct affections which cannot be differentiated, the one from the other, by studying the nervous phenomena alone—that we must rely upon some other feature in making the diagnosis? We are told that the varieties of epileptic attacks are innumerable, the distribution and severity of choreic movements is various, that the forms of hysteria cannot be recorded, but that each of these diseases in turn has a typical course and a general character.

2. We are also informed that nervous manifestations, arising from peripheral irritation, are characteristic, in their course, mode and period of appearance, frequency of occurrence of symptoms, and in the variation in relation to influences acting upon the patient. It would seem, then, that it is impossible to correctly diagnosticate true or false epilepsy, hysteria or chorea, until we have allowed sufficient time to elapse for a careful study of the course of the disease in question, and the general character of it. So that it will be necessary to inform a patient who comes to us with all the ordinary symptoms of epilepsy, for example, that we cannot make a diagnosis of his malady until several weeks or months have elapsed for our full study of the case, and, as a consequence, we cannot prescribe an appropriate treatment.

3. "It is also natural to believe that reflex cases readily become chronic unless the cause is removed, and do not yield to arsenical treatment, while in true chorea the influence of this treatment is usually evident by the time physiological effects are produced." It follows from this that it is of extreme importance to the patient that reflex chorea should be promptly diagnosticated as such, lest the patient become a chronic sufferer. As a differential characteristic of true chorea, we are to understand that the onset of the motions is more rapid, their situation more definite, the history of infection or fright more decided, and the accompanying anæmia and cardiac complications more uniform, than in any of the forms of reflex neurosis which simulate it. It would seem, therefore, that the difference between true chorea and reflex chorea is simply one of degree, not of quality, and no attempt has been made to mark the dividing line between the two, except, possibly, the crucial test of the arsenical treatment. In true chorea the influence of the arsenical treatment is usually evident by the time the physiological effects are produced, but reflex cases do not yield to arsenical treatment. Are we to understand from this that, given a case having the symptoms of chorea, the differential diagnosis is to be made by saturating the system to the physiological limit with a compound of arsenic?

Yours very truly,

J. H. Woodward, M.D.

Burlington, Vt., January 9, 1890.

CONCERNING THE STORAGE CELL.

To the Editor of the Medical Record.

Sir: In a communication to your journal which appeared recently there is made a statement regarding the use of the storage cell or accumulator for medical work which invites criticism. It is stated in the article referred to that the storage battery is not suitable for certain classes of work because the current furnished by it is too intense.

Leaving for the moment the absurdity of the objection out of consideration, it may be remarked that most people who use electric batteries endeavor to obtain cells which possess just this particular fault in the highest possible degree. That is to say, those cells which by their construction are capable of yielding the largest currents are the ones in greatest demand. It is not that large currents are always needed in medical work; indeed, ordinarily the current does not exceed the value of two hundred and fifty milliampères, yet were it possible to construct a good primary cell which could furnish continuously a large current, such a cell would leave nothing to be desired.

There is no class of medical work for which the storage battery cannot be used. Whether large or small currents are required, it matters not, the storage cell is suitable for either. Its electro-motive force is not much greater than that of the Bunsen cell (zinc-carbon-chromic acid), and therefore, with a given number of elements, in order to produce a current of a certain intensity we have to use almost the same resistance between the poles of the storage battery as we would between the poles of a Bunsen battery. It is, consequently, altogether erroneous to say that the storage cell gives currents of too great intensity. The current from the accumulator must be regulated just as the current from a Bunsen, or a Daniell, or a Leclanché, or a chloride of silver cell is regulated; in exactly the same way.

Regarding constancy of electro-motive force, there are few, very few, primary batteries which, in this respect, can compete with the storage battery. During discharge, provided this is not effected at too high a rate, the electro motive force of a good storage cell varies but little from about two volts. It begins with this value and maintains it until the cell is nearly exhausted. Of few types of primary cells in practical use can the same thing be said. The Daniell cell has a very constant electro-motive force when properly looked after, but it requires much attention. The cell first described by Latimer Clark has also an invariable electro-motive force; it is used as a standard in scientific work, but it is not a practical element and can only be employed when in circuit with enormously high resistances. The chloride of silver cell is a practical apparatus and has an electro-motive force which remains ex-

ceedingly constant. Heretofore these cells have labored under the disadvantage of having a rather large internal resistance. As a result of recent improvements, chloride of silver cells are now made whose internal resistance has been so much reduced that currents having a value as great as 1,100 or 1,200 milliampères readily are furnished by them.

A good primary battery is to be preferred to a storage battery, because the latter is useless unless there are means at hand for charging it when it has been run down. This is the real objection to the storage battery, and it is a serious one very often; but it is absurd to say that the secondary battery is too "intense" for medical work.

G. A. Liebig, Jr., Ph.D.

Johns Hopkins University, Baltimore, Md.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from January 6 to January 11, 1890.

Loring, Leonard Y., Major and Surgeon. By direction of the President will report in person to Colonel Benjamin H. Grierson, Tenth Cavalry, President of the Army Retiring Board at Los Angeles, Cal. Par. 3, S. O. 6, A. G. O., January 8, 1890.

Benham, R. B., Captain and Assistant Surgeon. By direction of the Secretary of War is relieved from duty in the Department of the Platte, to take effect upon the abandonment of Fort Laramie, Wy., and will then report to the commanding officer at Madison Barracks, N. Y., for duty at that station. Par. 8, S. O. 6, A. G. O., January 8, 1890.

Maus, Louis M., Captain and Assistant Surgeon. By direction of the Secretary of War leave of absence for six months, on surgeon's certificate of disability, is granted him, with permission to go beyond sea. Par. 13, S. O. 4, A. G. O., January 6, 1890.

Walker, Freeman V., First Lieutenant and Assistant Surgeon, Jackson Barracks, La. Granted leave of absence for one month, on surgeon's certificate of disability. Par. 7, S. O. 5, Division of the Atlantic, January 7, 1890.

Official List of Changes in the Medical Corps of the United States Navy for the week ending January 11, 1890.

Whiting, Robert, Passed Assistant Surgeon. Detached from the Minnesota, and ordered to the Dale.

Pickrell, George McC., Assistant Surgeon. Detached from the Dale, and ordered to the Minnesota.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending January 11, 1890.

	Cases.	Deaths.
Typhus fever	1	0
Typhoid fever	18	7
Scarlet fever	62	9
Cerebro-spinal meningitis	4	4
Measles	62	6
Diphtheria	106	28
Small-pox	0	0
Varicella	3	0
Cholera	0	0

Incompatibility of Antipyrine and Quinine.—Dr. T. W. Martin, of this city, writes: "In The Medical Record of November 23d I read with some surprise that 'a mixture of antipyrine and quinine is also incompatible, both substances being at once precipitated from the solution.' Now, as a matter of fact, I have found the combination the most effective of any I have tried in the treatment of intermittent and remittent fevers. I think I have prescribed the mixture with success in at least half a dozen cases this summer that have resisted treatment by quinine alone."

Treatment of Herpes Zoster.—Dr. B. O. Kinnear, of this city, referring to the report of a discussion on this subject at the meeting of the American Dermatological Association, recalls some cases treated by him by means of ice over the spine, a report of which was published in the Philadelphia *Medical Times* of April 15, 1889. He also reports a case occurring in a woman, fifty-four years of age, which he saw at Bar Harbor last summer, in which he obtained immediate relief with no resulting ulceration or neuralgia. It was a case of zoster pectoralis, and promised, when first seen, to prove very troublesome, but in twenty-four hours the pain was much relieved, and several ulcers which had formed were looking healthy.

Human Milk of Low Temperature.—Dr. G. F. Inglott writes to the *British Medical Journal* that a woman came to his consulting-room stating that her child, six months old, refused since ten days ago to take her right breast. After inquiry it was found that the patient, aged thirty-five years, and strong in constitution, had suffered at the age of twenty years from severe hysterical fits of convulsive and non-convulsive form, which lasted for a long time. Her menses commenced at the age of fifteen, recurred regularly every month and were rather profuse, lasting about eight days each time. She had seven children, of whom six were alive, and of good constitution. On examining the milk the writer was highly surprised in finding it as cold as iced water. He was much interested in the case, and, after careful consideration, came to the conclusion that it was a nervous phenomenon due to the hysterical state of the woman. He prescribed, therefore, one drachm of bromide of potassium daily in a decoction of cinchona-bark, and a mixture with camphor and valerian. After ten days' treatment the milk acquired its normal temperature, and the child began to suck the breast again.

An Injection in Cancer of the Uterus.—Dr. Chéron recommends the following injection in cases of uterine cancer, with a fetid discharge: ℞. Salicylate of sodium, 20 parts; salicylic acid, 1 part; tincture of eucalyptus, 45 parts; distilled vinegar, 300 parts. From one to five tablespoonfuls to be added to a pint of water, and used as a douche several times a day.—*L'Union médicale*, No. 114, 1889.

Lassar's Treatment for Baldness.—*First Stage:* A strong tar soap is applied to the scalp for at least ten minutes. *Second Stage:* Removal of soap by a tepid water douche, the water to be gradually cooled, the scalp to be well dried afterward. *Third Stage:* The scalp to be shampooed with the following solution:

℞. Hydrarg. bichlorid. corrosiv. ..... gr. x.
Glycerin,
Spirit. rect. ..... āā ℥ ij.
Aq. destil. ..... ℥ v.
F. fiat solutio. S.: For ext. use.

Fourth Stage: Shampooing of head with absolute alcohol, to which half per cent. of naphthol has been added. *Fifth Stage:* The following solution to be well rubbed into the skin:

℞. Acid. salicyl. ..... gr. xxx.
Tinct. benzoic. ..... ℥ j.
Ol. ped. taur. ..... ad ℥ iij.

Graetzer found this treatment most useful and efficacious in private practice, and therefore does not hesitate to recommend it to the profession. He says that with such a powerful method of treatment in view, the present indifference of medical men with regard to the treatment of alopecy ought to be given up.

Tit for Tat.—It is asserted that the proprietor of *Tit-Bits* has promised to give $50,000 to certain hospitals in England on condition that the circulation of his journal shall average half a million copies per week during the coming year.

Female Medical Students in Scotland.—An association has recently been formed in Edinburgh, with the approval and support of some of the most eminent practitioners there, which has for its object the promotion of female medical education.

Hinc illæ Lachrymæ.—It is said that the contagion of measles resides in great part, if not chiefly, in the tears. Experiments with inoculation shows that a mild form of the disease can be so produced, and it is proposed to practise this method in epidemics of a severe type, in order to mitigate the virulence of the disease.

The War upon Cigarettes.—The South Carolina Legislature, at its last session, passed a law forbidding the sale of cigarettes to minors, and imposing a severe penalty for its infringement. The juvenile population in the Palmetto State is said to be strongly wedded to the cigarette, and its grief at the passage of the law is equalled only by the indignation of the tobacconists.

A Glimmer of Returning Reason.—According to a recent cable despatch the leader of a band of vegetarians in Berlin has separated from his fellows, and abandoned a purely vegetable diet, on the ground that it leads to atheroma and calcareous degeneration of the arteries. Dr. Alanus, for so he is called, exhibits symptoms of great promise, and we cherish hopes of his complete restoration to mental health.

Death from Drinking Arsenical Waters.—It is stated in the *Popular Science News* that there is a spring in Belgium the water of which contains seven-tenths of a grain of arsenious acid to the gallon. The water had been introduced into a large institution, and it was the unexplained death of several of the inmates that led to an investigation and the discovery of the poisonous quality of the water. La Bourboule and some other springs contain arsenic among their other ingredients, but no natural water has ever before been found which held so large and dangerous an amount as this.

A Rare Exhibition of Gratitude.—It is so seldom that a physician receives any public recognition of his services, that when such a thing does happen it is worthy of mention. Stanley has shown that he has gratitude among his other virtues, for the despatches from him contain many references to the devotion and skill of the physician of his expedition, Dr. Parkes, and he generously attributes to him a large part of the credit for the success of the undertaking.

An Epidemic of Raphania, a convulsive disease due to chronic ergotism, is reported in the Vjatka Government in Russia. The number of persons attacked amounts to 683, of whom 34 have died up to the present. The Kazan Medical Society has deputed Dr. Kondoratski to make a special study of the disease.

Cruelty to the Insane.—A commission recently appointed by the Governor of Pennsylvania to investigate charges made against the keeper of the Du Page County Poorhouse has reported that the insane inmates suffered great cruelties at the hands of the attendants.

The American Academy of Medicine wants more members, in order to widen its influence and to hasten the time when the object of its foundation and existence shall have been attained. All physicians possessing the necessary qualifications, who believe in the desirability of a good preliminary education and in the power of organization to effect reforms, should respond to the invitation of the Academy and enter its ranks prepared to fight in the cause of education.

Dengue Fever is reported to be prevalent in Greece, over two thousand of the inhabitants of Athens alone having been laid up with it during a single week. It is possible that the supposed dengue is nothing more than a form of the influenza in which the "break-bone" pains are specially prominent. Numerous cases of that sort have been seen in this city since the appearance of the epidemic.

The Pay of German Army Surgeons.—That the remuneration which the German Government has thus far bestowed upon its medical officers, writes the Berlin correspondent of the *Therapeutic Gazette*, is but a meagre one is revealed by the recent proposal to raise the salary of the general *Stabsarzt*. The salary of this gentleman—the highest medical officer of the army—amounted to but two thousand three hundred dollars. In view of his exalted office, the unavoidable obligation of representation, and the preclusion of private practice, it is to be hoped that the proposed advance in his salary will be granted.

The Marriage-rate in England has shown a remarkable falling off during the past few years, according to the reports of the Registrar-General. The statisticians seem to be baffled in their efforts to account for the decrease, as there is no war on hand and the times are not specially hard.

The Money Value of a Health Officer.—Dr. Baker, of the Michigan State Board of Health, estimates the value of an efficient health officer to any community at the rate of nearly $1.50 per capita per annum, in the matter of life-saving alone, and leaving out of consideration the amount of sickness prevented. He shows by a comparison of statistics that the lives of one adult and two children may be saved each year, on an average, in a community of fifteen hundred souls, through the effort of a health officer who will see to it that the recommendations of the State Board of Health are carried out. Estimating the value of an adult life to the community at $1,000, he thinks that a village of this size may well afford to have a health officer at a salary of $2,000.

Drunkenness is Increasing in Russia, according to Dr. Kovalevski, of St. Petersburg.

An Eighteenth-century Opinion of Medicine.—The opinions of a writer in the early part of the eighteenth century are quoted by the *The Hospital*, as follows: "It is a very difficult science, because the theory depends upon the understanding and the practice upon the imagination. It is full of dangers to the patient, because it is founded upon conjectures; and, according to Plato, the conjectures of physicians are very uncertain."

The Kola-nut and Cholera.—It is stated that those regions of Africa where the use of the kola-nut by the natives obtains have never been visited by cholera.

Ava-drinkers in the Sandwich Islands.—The immoderate consumption of "ava" causes a peculiar affection of the skin characterized by redness and infiltration in the epidermis. The drinkers of the beverage are usually emaciated, and the surface of the body is covered with scales, which become detached, leaving small ulcers. The lesions are not permanent, but gradually disappear when the habit is abandoned. Among the natives the ava formerly enjoyed considerable reputation as a remedy for leprosy.

Tonsorial Disinfection.—The authorities at Nordhausen, in Saxony, at the suggestion of the district medical officer, have issued an order to barbers to disinfect their brushes and other implements immediately after use, and before they are applied to the hair or beard of another customer.

Pombolano is the name of a plant found in Mexico, the root of which is said to contain a substance analogous to but more powerful than, quinine in its antiperiodic action. It has been found to cure rebellious intermittent fevers that had resisted the action of quinine.

ON THE GERMICIDAL ACTION OF BLOOD-SERUM AND OTHER BODY FLUIDS.

By T. MITCHELL PRUDDEN, M.D.,

DIRECTOR OF THE LABORATORY OF THE ALUMNI ASSOCIATION OF THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

The definite proof that a large number of the most important of human diseases are caused, and caused alone, by bacteria, and the vast amount of knowledge which has rapidly accumulated about them under the stimulating influences of the new technique, have been most satisfying, and have made possible many promising glimpses into the domain of prophylaxis and treatment. It is, therefore, not surprising that a large part of the current medical thought and speculation should still find abundant food in the more or less simple relationship which appears to exist between a few well-known diseases and the bacteria which cause them.

But it has already become evident that the restless impulse of research is by no means to be satisfied with these elementary phases of the etiology of disease. A large number of subsidiary, but by no means simple or unimportant, problems are urging solution.

The nature of the poison by which the bacteria produce their effects in the body, and the varying reactions of the cells in the presence of these poisons, form a series of problems which tax to the utmost the resources of both the chemist and the biologist. The question of immunity from bacterial disease, either natural or acquired, has, from the first, been a most potent stimulus to speculation and research. The various conditions of the body which evidently predispose it to the incursions of disease-producing bacteria, whether acquired by heredity, by exposure, or in any one of many possible ways, suggest most important, and as yet most obscure, fields of inquiry, both at the bedside and in the laboratory.

One of the most frequent questions which is heard, as one after another the lurking-places and wide distribution of some of the pathogenic micro-organisms are brought to light, is, Why, then, do we not all suffer or die from bacterial disease? The answer to this, often half-impatient query, is many-sided, and cannot be completely given yet.

The application of our new knowledge to clinical observations, old as the science of medicine itself, teaches us that there is in the body some sort of adjustment of forces by which, under ordinary and favoring conditions, the deleterious effects of pathogenic bacteria are neutralized or limited, and the organisms themselves disposed of.

The very occurrence of self-limiting diseases, such as typhoid fever, acute lobar pneumonia, etc., strongly suggests, if it does not prove, the existence in the body of some sort of bacteria-destroying agency. But a long series of animal experiments has definitely proven that a very considerable number of pathogenic micro organisms may be introduced into the body, to entirely disappear in a short time.

To account for the disappearance of pathogenic bacteria in the body, either in the course of an acute infectious disease, or as the result of exposures which we may sustain unharmed, several more or less plausible theories have been evolved.

That one of these which has attracted most attention, partly because it has been most ably advocated, and partly because it lends itself readily to experimental observation, is that called the theory of phagocytosis. This theory is too well known to need detailed exposition here. Suffice it to say that it postulates the taking up into their bodies and the destruction there of living micro-organisms, by certain lowly organized cells, especially the leucocytes. A large amount of very plausible experimental evidence has been adduced in favor of this theory, and a good deal of this evidence has been unconditionally accepted by medical men. Metchnikoff, the chief expounder of the theory, claims that this destruction of the life of bacteria by being taken into the bodies of certain cells—phagocytes—is the exclusive means which the organism makes use of in resisting the incursions of pathogenic bacteria. An animal whose leucocytes can successfully battle with and eat up a given species of bacteria, according to this theory, enjoys immunity from its deleterious effects.

But the doctrine of phagocytosis, at least in the scope which is claimed for it, appears to most unprejudiced observers less and less to commend itself the more the facts and observations on which it is based are critically examined and judiciously interpreted.

The series of observations on which this theory largely rests, varied and elaborated in many ways, indisputably teach this—that when micro-organisms are introduced into the body, either naturally or artificially, the phagocytes which gather about them may be found after a time to have taken more or less of the germs up into their bodies, where they show those morphological evidences of degeneration which indicate that they are dead. That this phenomenon does occur is well enough established, but that it should be interpreted as necessarily meaning that the micro-organisms are taken in the living condition into the cell bodies and there deprived of life, appears to be very doubtful indeed. That the leucocytes and other lowly organized cells are capable of taking up dead and used-up material into their bodies, and that the leucocytes are more or less constantly engaged in transporting and disposing of such material in various parts of the body as a physiological process, is well known. But the observers of phagocytosis, as applied to micro-organisms, have never shown that the bacteria which the cells unquestionably do take up into their bodies were alive when they were taken in; and unless this can be shown, no proof exists that the action of phagocytes toward bacteria is in any way different from that toward any of the other various dead material which they absorb or transport.

Résumé of Recent Observations.—Nutall[1] has recently made a series of observations with the view of determining whether, after all, the bacteria which are taken up by leucocytes under these conditions are not dead. In fact, he found, on repeating Metchnikoff's experiments with anthrax put into both cold- and warm blooded animals, that many bacilli were found inside the bodies of the leucocytes, and exhibited there the structural changes indicating death. But he found also—which obviously puts a very different light on the matter—that the bacilli which lay in the body fluids which were about the leucocytes showed, under the same conditions, the same degenerative appearances indicating death that those within the cells did. Death in the free bacilli could not have been caused by the intra-cellular

[1] Nutall: Experimente über die bacterienfeindlichen Einflüsse des thierischen Körpers. Zeitschrift fur Hygiene, Bd. iv., p. 353.

action of protoplasm, but must be due to some other agency.

Nutall found, furthermore, that the appearance of degenerated bacilli in the bodies of leucocytes went hand in hand with the degeneration of those outside; the more rapid the degeneration of the free bacilli, the more abundant were they in the leucocytes.

These observations lead directly to the conjecture that it is some agent in the fluid constituents of the blood which destroys the germs.

In order further to prove this point, and to give more exact data than is afforded by a simple microscopical observation, fresh blood was drawn from animals, rapidly coagulated by shaking with sterilized sand, and still being kept warm, was divided into small parts and inoculated with the anthrax bacilli. The number of living germs which was put into each tube was immediately accurately determined by making plate cultures. The remainder of the blood-serum was now distributed in small quantities and placed in the thermostat at about body temperature, and from time to time some of the tubes were taken out and plated, and the colonies, when grown, counted. The general result of these experiments with rabbit's blood and anthrax was that a rapid destruction of the bacilli occurred. To take an example: At first there were about 90,000 living bacilli; on standing for one hour in contact with the serum there were about 33,000, and after four hours all were dead. In some cases the bacilli were not all killed, but the number greatly reduced, and then, singularly enough, after a time the number was found to increase.

It thus appeared that the destructive agent in the blood-serum was limited in its capacity to destroy bacteria, becoming itself used up in the process. Furthermore, it was found, by another series of experiments, that the bacteria-destroying power of the blood-serum diminished with the lapse of time. Heating the serum to from 50° to 55° C. destroyed entirely the killing-power.

Nutall now tried the effect on living bacteria of fresh body fluids which contained but few leucocytes, namely, humor aqueous, and liquor pericardii, and found that in these, too, the bacilli were killed and degenerated in the same way without the presence of cells.

Finally he tried other species of bacteria than anthrax, and found that while B. subtilis was rapidly destroyed by blood-serum and B. megaterium to a considerable degree, the staphylococcus pyogenes aureus was unaffected by it.

Buchner,[1] continuing this line of study with an improved technique, was able to separate the fresh blood-serum from its cellular elements, and his experiments, while confirming the results of Nutall, brought to light many new facts about the germicidal action of fresh blood-serum.

To summarize his results: Buchner found that the fresh blood-serum of certain animals, freed from cells, had the power of rapidly killing various species of bacteria. The degree of this killing-power varies in the serum of different animals; thus it is greater in the dog than in the rabbit. Different species of bacteria vary widely in their vulnerability to the serum. Neutralizing the strongly alkaline blood-serum of the rabbit does not interfere with its bacteria-killing power; dilution with water diminishes but does not destroy it. The germicidal capacity of the fresh blood-serum is limited. Thus Buchner found that 1 c.mm. of rabbit serum would kill about 1,000 typhoid bacilli, but if more than this proportion was added the destruction was incomplete.

So far as the vulnerability of species is concerned, Buchner found that they varied greatly, some being easily killed, others quite resistant. He found that while the germicidal power of blood-serum is most marked when freshly drawn, it yet may preserve this power, in diminishing but evident degree, even for several days.

[1] Buchner: Ueber die bakterientödtende Wirkung des zellenfreien Blutserums. Centralblatt für Bacteriologie, etc., Bd. v., No. 25; Bd. vi., No. 1.

It appeared to Buchner that in all of these experiments with fresh blood-serum there are two antagonizing influences at work, namely, the nutritive power and the killing-power; and that the numerical results which we get show simply the difference between these. For blood-serum which is kept for some time, until its bacteria-killing power is lost, or which is heated for an hour to 55° C., is good bacterial food. It thus appears that when the blood-serum more or less rapidly kills off the germs, it does so because its destructive are in greater or less excess of its nutritive qualities. This was very neatly shown by adding to fresh blood-serum varying quantities of alkaline meat peptone, and testing its effects on bacteria. It was found that, when the peptone solution was present in relatively large proportion, the number of bacteria which were present in the plate after from two to five hours was very much larger than that originally sown. As the relative proportion of the peptone diminished, however, the killing-power revealed itself, and at last so far overbalanced the nutritive capacity as to sterilize the cultures.

It thus appears that the red blood-cells, as the blood disintegrates, may furnish food for the bacteria. This would explain why, in Nutall's experiments, in which the red blood-cells were mingled with the serum, after a time, if the bacteria were not all soon killed, they began to rapidly increase in number.

In order to prove this assumption, however, Buchner simply froze the blood, a process which results on thawing in a large solution of the red blood-cells. Such blood was found to have lost its bacteria-killing power. To establish the force of this experiment, Buchner proved that the freezing and thawing of corpuscle-free-blood-serum did not in the least diminish its bacteria-killing power.

That the process of coagulation itself is not responsible for the germicidal action of the blood, was shown by testing upon typhoid bacilli the effect of blood which was prevented from coagulating by the intra-venous injection of peptone in considerable quantities into the dog. It would appear that the phagocytes are not directly concerned in producing these effects of blood-serum, first, because they occur in serum which microscopically is found to contain none; second, because when the serum is carefully filtered, the filtered is equally efficient with the unfiltered serum in destroying the germs; and third, because freezing and thawing, even repeatedly, which kills the leucocytes and thus removes the possibility of an active combat with the germs, does not in the least reduce the killing-capacity of the serum.

Buchner has further shown, by experiments on blood-serum by dialysis, that this germicidal power is associated with its albuminoid constituents.

Nissen [1] has also shown, by a study of many species of pathogenic and non-pathogenic bacteria, that different species vary widely in their vulnerability to fresh blood-serum.

The enormous number of certain bacteria which can be killed by blood-serum is shown by a series of experiments, in which 3,600,000 of coccus aquatilis, by one hour of contact with serum, had been reduced to 45; while in the same period 1,200,000 of the Bacillus choleræ asiaticæ were reduced to 2,000.

It appeared from Nissen's studies, that the time of maximal killing of coccus aquatilis is from five to ten minutes; of B. choleræ asiaticæ from twenty to forty minutes; of the B. typhosus, two hours. There is a maximal number of bacteria beyond which the killing-power ceases.

Lubarsch [2] has found that, so far as anthrax bacilli are concerned, the circulating blood of rabbits and cats is not so vigorous a germicide as the extra-vascular blood. This he would explain by the consideration that living bacteria in considerable numbers, thrown into the blood,

[1] Nissen: Zur Kentniss der bacterienvernichtenden Eigenschaft des Blutes. Zeits. f. Hygiene, Bd. vi., p. 487.

[2] Lubarsch: Ueber die Bakterienvernichtenden Eigenschaften des Blutes, etc. Centralblatt f. Bakteriologie, etc., Bd. vi., Nos. 18, 19, 20.

disappear from this in a very short time and collect in the liver, spleen, and bone-marrow. But as in these situations red blood-cells are destroyed, he argues that the nutritive qualities of the blood here become so marked as to mask the destructive process, as Buchner had shown to be the case in frozen and thawed blood.

Lubarsch also calls attention to the fact that the blood-serum of those animals which, either naturally or artificially, are comparatively little susceptible to the action of the anthrax bacillus, is no more potent to kill this germ outside of the body than is the serum of animals which readily succumb to its effects.

While so much as has been here epitomized appears to have been pretty well established as to the germicidal action of the blood-serum of animals—and this has also been shown to be true of human serum—it has seemed to the writer important to ascertain whether some of the body fluids which appear in transudations, and are more or less directly associated with life processes of the tissues, possess similar germ-killing capacities.

Original Experimental Studies.—I have selected for my experiments two well-defined species of pathogenic bacteria, namely, the bacillus typhosus and the staphylococcus pyogenes aureus. The typhoid bacillus was obtained from the spleen of a person dead of typhoid fever, and it had been under cultivation in the laboratory for several months. Fresh cultures were made for each set of experiments, so that a vigorous culture of from three to five days old was always employed. The staphylococcus pyogenes aureus (S. p. a.) was obtained from a suppurating wound, had been but a few weeks under cultivation, and cultures from two to four days old were always used.

The technique was essentialiy that indicated above in the review of the work on blood-serum by the German observers.

The fluids whose germicidal powers were to be tested were obtained from the living body under strict antiseptic precautions, and in each case a portion of the fluid was planted in nutrient gelatine and found to be absolutely sterile.

Each specimen of fluid, as soon as obtained, was distributed in about 2 c.c. amounts in a series of sterilized cotton-plugged test-tubes preparatory to inoculation.

The inoculating material was prepared by mixing intimately a very small portion of the pure culture of the bacteria (typhoid bacilli or S. p. a.) with a few c.c. of sterilized distilled water, or ¾ per cent. salt solution, in a sterilized test-tube. Approximately equal quantities of this bacterial emulsion were taken out by means of a fine platinum wire-loop, and mixed with the portion of fluid to be tested in each one of the tubes.

The number of living bacteria which were thus introduced into the separate portions of fluid was determined by planting a loopful of the same bacterial emulsion in nutrient gelatine and pouring the mixture into a sterilized, shallow, covered glass dish (Petri's plate), and when the bacteria thus planted were grown, counting the colonies. In order to insure greater accuracy, triplicate plates and counts were made for the determination of this norm.

Now, at intervals after the inoculation, the entire amount of the fluid in two of the inoculated tubes was plated, and the colonies when grown counted. Duplicates were in all cases made for the sake of greater accuracy.

It is evident that the comparison of the number of colonies in the original or normal plates with the number of colonies in the plates made at various intervals after the inoculation of the fluids to be tested, will, allowing for the experimental error which in such work as this is considerable, give the approximate germicidal capacity, if any exists, of the fluids to be tested upon the particular cultures employed. It is true that in such experiments as these we assume that the failure of the planted bacteria to grow and form colonies is to be taken as an indication of the death of the germs. While this inference may not with all classes of germicides be justified, within the limits of these experiments it would seem to me to hold good.

The body fluids tested in this way were ascitic fluids drawn from the abdomen of a case of cirrhosis of the liver, and from a case of chronic Bright's disease;[1] simple hydrocele fluids, one from a young, one from an old man; the amniotic fluid from the pig; and fresh normal human urine.

Before these experiments were begun, I repeated the experiments of the German observers with blood-serum, testing the effects on the typhoid bacillus and the S. p. a., of the fresh serum of the dog, rabbit, beef, pig, and sheep. The results of these preliminary experiments with blood-serum need not be given in detail here, as they were simply confirmatory of the experiments reviewed above, showing that in varying degrees the fresh blood-serum of these animals is inimical to the life of the typhoid bacillus, but not at all, or in but slight degree, to that of S. p. a.

Returning now to the effects of fresh ascitic and hydrocele fluids on the typhoid bacillus and S. p. a., the results may be best shown in tabular form. While these experiments were all done in duplicate, the numbers were so closely alike in the two sets that I have, for the saving of space, given only the averages. I have also given only a small proportion of the experiments performed, these being entirely typical of the whole series.

TABLE I.—*Experiments on the Effects of Fresh Ascitic and Hydrocele Fluid on the Typhoid Bacillus.*

	Ascitic Fluid.		Hydrocele Fluid.				
No. of experiment	I.	II.	I.	II.	III.	IV.	V.
Number of bacilli planted	5,764	13,725	200	2,360	1,620	1,280*	2,880†
Hours of exposure of the bacilli to the fluids: 1	....	.....	31	7	11	178	...
2	305	4,666	23	...	....	.....	2,010
3	638	.....	...	5	10	208	....
4	....	2,775	...	....	....	.....	2,839
5	...	.....	.	14	5	166	....
7	127	.	...	...	....	.....	...
19	....	975	...	....	....	.....	2,100
24	107	.....	0	16	4	8	2,253

* Five days old. † Heated one hour to 60° C.

These experiments show, first: That freshly drawn ascitic fluid from a case of cirrhosis of the liver, and from a case of chronic Bright's disease, and from two cases of simple hydrocele, were capable of promptly killing large numbers of typhoid bacilli, or at least rendering them permanently incapable of growth on nutrient gelatine. Second: That this destructive capacity may be retained to a considerable degree for several days. Third: That heating the fresh transudate to 60° C. for one hour practically destroys the destructive power.

But it may be justly urged that we do not know what part of the destructive action, which is evident in these experiments, may be accounted for by what may be called the natural or spontaneous death of the typhoid bacilli when placed in innutritious fluids, such, for example, as distilled water or salt solution.

This element is accounted for by the results of the experiments shown in Table II.

TABLE II.—*Experiments on the Effects of Distilled Water and Salt Solution on the Typhoid Bacillus.*

	Water.					Three-fourths per cent. Salt Solution
No. of experiment.	I.	II.	III.	IV.	V.	I.
Number of bacilli planted	2,020	732	1,982	24,979	2,360	2,020
Hours of exposure of the bacilli to the fluids: 2	2,562	957	2,875	25,713	..	1,921
3	...	...	.....	..	2,100	...
4	1,576	858	3,577	31,459	....	2,348
5	...	...	....	.. ..	1,590	...
7	2,135	...	....	...	...	2,286
19	...	...	...	...	...	...
24	1,658	238	1,811	28,456	994	1,539

These experiments show that while the effect of water on the typhoid bacilli planted in it is in general to reduce

[1] I am indebted for these fresh fluids to Drs. Otis, Johnson, Wiggins, and Painter.

the number of viable individuals considerably within twenty-four hours, still the number may be increased. This increase in the number of bacilli planted is often most evident within the first two or three hours, a period which in the transudate-fluid experiments is marked by the greatest diminution in numbers.

It is thus evident that the destruction of the typhoid bacillus by fresh ascitic and hydrocele fluids is not dependent upon the simple physical character of the medium, but upon some element in its constitution which stands in close relationship with the vitality of the organism from which it was derived.

The following table shows the results of another series of experiments on different forms of fresh body fluids:

TABLE III.—*Experiments on the Effects of Fresh Liquor Amnii of the Pig, and Fresh Human Urine on the Typhoid Bacillus.*

	Liquor Amnii, Pig.		Urine, Man.	
No. of experiment	I.	II.	I.	II.
Number of bacilli planted	54,432	52,236	6,759	350
Hours of exposure of the bacilli to the fluids: 1	91,500	99,096	8,385	320
2	.....	.....	....	295
3	178,200	190,840	9,641	...
5	... ...	.....	....	...
6	216,000	201,240	8,897	...
24	Innumerable.	Innumerable.	3,000	77

These experiments show, that not all fresh body fluids are capable of rapidly destroying the life of the typhoid bacillus. For while the effect of fresh human urine is much the same as that of pure water, the liquor amnii of the pig acts as an excellent food, in which the bacilli proliferate with such rapidity as to entirely mask any destructive agency which the fluid may possess.

The effects of fresh transudation fluids on the staphylococcus pyogenes aureus is shown in Table IV.

TABLE IV.—*Experiments on the Effects of Fresh Ascitic and Hydrocele Fluids on the Staphylococcus pyogenes aureus.*

	Ascitic Fluid.		Hydrocele Fluid.	
No. of experiment	I.	II.	I.	II.
Number of cocci planted	19,764	9,607	6,322	2,130
Hours of exposure of the cocci to the fluids: 1	.....	.....	3,510	....
2	13,999	.....	2,702	....
3	.....	13,725	....	2,580
4	.....	17,568	....	....
5	.....	.....	....	3,090
7	6,656	7,686	....	....
24	7,411	.....	1,354	2,314

These experiments show that upon the staphylococcus pyogenes aureus, fresh ascitic and hydrocele fluids exert no marked destructive effect, the gradual diminution in number observable, after some hours of exposure, being no more marked than when these bacteria are planted in pure water, or ¾ per cent. salt solution.

Summary.—It would thus appear, as the general result of all this recent work that fresh blood-serum possesses, though in different degrees in different animals, and in varying potency with the different bacterial species, a most marked germicidal power; that a similar germicidal power resides in fresh human non-inflammatory transudations. That this power is not directly associated with the formed elements of the blood or transudates, but is in some way dependent upon their albuminoid constituents. It would furthermore appear that this singular, and apparently most significant, capacity of the body fluids is intimately associated with that complex condition which we call life.

Remarks.—The significance of these new discoveries would seem to be very great and far-reaching, not only in explaining many obscure phenomena of the acute infectious diseases, and in their bearing upon the doctrine of immunity, but also in calling back the attention of therapeutical adventurers from germicidal warfare with certain forms of infectious disease, to what appears to be a natural defence of the organism against bacterial invaders, namely, a healthy condition of the blood.

But our knowledge on this subject is too fragmentary and too little digested to permit us to do more at present than follow the general indications of its lead. More facts is what we need now.

While it is evident that the theory of phagocytosis, as applied to the infectious diseases, is by no means of the significance which has been assumed, it is equally obvious that to base a comprehensive theory of immunity on this remarkable germicidal power of some of the fresh body fluids would be premature.

The fact that one of the most abundant of the pathogenic bacteria—the staphylococcus pyogenes aureus—appears to be quite invulnerable to this destructive agency, would indicate the necessity of cautious inferences.

We seem in these studies to be straying somewhat beyond the limits of those fields of morphological and biological observation in which such vastly important discoveries have been made within the last decade, and to be treading the somewhat uncertain ground of physiological chemistry, and that, too, in a part of its domain in which the crust over chaos is not yet very solid.

Proud of our already long list of well-defined bacterial species; consciously masters of the morphology of many forms of bacterial disease; well on the way to an intelligent and efficient prophylaxis; and glorying in the possession of ptomaines so definite as to enter at our will into the composition of tangible and even formulatable metallic salts; it is a little humiliating, though doubtless salutary, to find ourselves face to face with a series of phenomena which seem to lie at the very basis of the knowledge of the acute infectious diseases, and yet able to say only—they are the result of the vital forces—vitality, life. It is fortunate that we have these words and phrases, however, which conceal so much and express so little, since, under their cover, we may take breath for the assault on another of Nature's tantalizing and well-fortified secrets.

December 31, 1889.

THE EFFICACY OF WORMWOOD (ARTEMISIA ABSINTHIUM) IN CERTAIN CONDITIONS OF THE CEREBROSPINAL AXIS.

BY J. LEONARD CORNING, M.D.,

NEW YORK.

IN the quest for the new, it too often happens that we forget the advantages of the old. This is especially true of remedies. By this statement I do not wish to imply that the medical literature of the day is not sufficiently retrospective; for, indeed, as everybody knows, a goodly section of it is saturated with platitudes—a fact which induced a distinguished physician to observe, not so very long ago, that nine tenths of such literary work had better never been done at all. The point, however, which I desire to make is, that not only do we forget the virtues of old remedies, but that we frequently fail to detect new and appropriate spheres of usefulness for those favorites of former years, all too prematurely discarded.

Without philosophizing on this point further, I will state at once that in my judgment absinthe is one of those useful drugs which, forgotten by the profession, is thrice appreciated in the wine-shop. Nobody questions the harm wrought by wormwood in its rôle of servant to human debauchery; the statistics on this point are overwhelming. But so are they as regards opium, hashish, coca, alcohol, and many other drugs; and yet we do not hesitate to employ these substances for curative purposes, and, indeed, it is hard to say how we should get on without them.

The popular abuse of a drug is, therefore, clearly no bar to its employment medically. This, at all events, is the view held by the vast majority of the profession, and

very properly so held. I shall offer, then, no apology for what I am about to say regarding this excellent, though greatly abused, medicament.

About all that I have been able to learn from previous publications regarding the medicinal virtues of this plant is as follows:[1] I find that it has been employed in the treatment of epilepsy, chorea, and digestive disorders; while, before the introduction of Peruvian bark, it was also used in intermittent fever. Regarding its supposed anthelmintic qualities, the statements of authors are less definite. As a discutient and antiseptic, however, the drug seems to have met with some favor. Whatever difference of opinion may exist as to the efficacy of wormwood when employed in the conditions previously described, there can be no doubt regarding its remarkably tonic influence upon the brain, and especially upon those higher mechanisms of the organ which are so intimately associated with psychical function.

Possessing, as it does, these tonic properties in such full measure, it is matter of surprise to me that absinthe is not extensively employed in neurological medicine. In the treatment of those exhaustive conditions of the cerebro-spinal axis commonly known as "neurasthenia" it is certainly a valuable remedy—valuable, because it dissipates the hebetude, depression, and indefinable sensations of malaise from which such patients periodically suffer, in a few moments. I have used absinthe in such cases, from time to time, during the last few years, with no little satisfaction. In two cases of typical cerebral exhaustion recently referred to me for treatment by my eminent friend Dr. David Webster, of New York, I had recourse to moderate doses of absinthe on several occasions with the happiest results. Both of these patients were business men in middle life; both suffered from periodic attacks of depression, morbid apprehension, and acute irritability; and both had been advised to give up business. The recommendation to give up business, so commonly made in cases of this sort, I regard as unfortunate; because the mind of the patient, being no longer occupied with the affairs of the external world, is given over to a flood of morbid introspection, which serves to increase the apprehension and depression of the patient, and, in a word, aggravates the whole psychological complexion of the case. Of course, when the exhaustion is so extreme as to render mental and physical exertion positively painful, there is nothing for it but to tell the patient to stop work. When, on the other hand, he can get about and exert his mind to a moderate degree without evoking painful sensations or mental confusion, I think it is better to let him do so. His depression, his irritability, his hypochondriasis, his general malaise, must be looked to by the medical attendant. And it is just here that absinthe serves an excellent purpose; for, by a conservative exhibition of the drug we may modify, and, indeed, entirely obliterate, for some time at least, the distressing psychical features of the case. Moreover, this may be done without inducing more than a slight feeling of exhilaration—an effect which, even according to the most rigid interpretation, is not comparable with intoxication.

This power of promptly relieving the most exigent symptoms—those of a mental character—is of vast importance, since it enables one to render the condition of the patient comparatively comfortable; while remedies potent, though lethargic in their action, may be employed for the permanent eradication of the disease.

I have been thus explicit, not because of any intention of giving an exposition of all the features of the treatment applicable in neurasthenic cases, but because of a desire to indicate with precision the part which absinthe is capable of taking in the management of such cases. This I trust I have succeeded in doing.

Depressive Action of the Essential Oil of Absinthe on Cutaneous Sensibility.—Every medical man is probably aware of the toxic properties of the essential oil of wormwood, which in large doses evokes convulsions, involuntary evacuations, unconsciousness, and even death. There are, however, other properties exhibited by this oil, no mention of which, so far as I know, is made in the books. One of the most significant of these attributes is its ability to obtund the sensibility of the cutaneous nerves. Indeed, so pronounced is this effect that when the oil is injected into the skin—below the epidermis or into the superior strata of the chorion—a condition is speedily set up amounting practically to anæsthesia. The insensibility may be furthermore enhanced by keeping the oil in place by the aid of appropriate devices.[1] These facts were known to me long ago—at least three years since—the experiments which I then undertook being conducted with long, fine, hypodermic needles, so that an accurate placing of the oil in the skin was accomplished without difficulty and almost without pain.

General Analgesic Properties of the Drug. — The reputed effect of wormwood upon temperature, conjoined with what I had ascertained regarding its action upon peripheral sensibility, aroused in my mind the suspicion that the drug might possibly possess more general analgesic properties. Accordingly I tried it in a variety of painful conditions, and more particularly in headache, spinal irritation, and muscular rheumatism. In the two first-named conditions it was undoubtedly beneficial; at least this was true of a number of cases in which relief from pain was obtained in from twenty minutes to half an hour. In the cases of muscular pain, and more especially in lumbago, the effects obtainable were less striking. As a matter of curiosity, I may add that I have seen the pains and depression of that protean distemper called "la grippe" greatly relieved by absinthe. These general analgesic properties of wormwood are not as pronounced as those of phenacetine or antipyrine; still, they are sufficiently apparent to render the drug of some value in the management of the milder degrees of pain.

When I first began these investigations the body known as "absinthin" excited my curiosity. I went to considerable trouble and expense in having the drug imported, through Merck, of Darmstadt; but I must confess that, so far as I was able to ascertain, the preparation is practically worthless. As regards the best form of administering absinthe, I would state that in my judgment preference is to be given to those extracts and wines which have been in the market for so many years. It is true that to these preparations various substances have been added; but these latter, in so far as any considerable physiological effect is concerned, possess a purely collateral importance, which in no way militates against the free action of the wormwood.

On the other hand, the preparations of the Pharmacopœia are less satisfactory.

53 West Thirty-eighth Street, January 1, 1890.

[1] For a more explicit account of wormwood, see the Dispensatory of the United States of America, page 2 (sixteenth edition), 1888.

[1] This factor has been exhaustively treated of in former writings of the author.

Swallowing a Tooth-brush.—Dr. Hashimoto relates the case of a woman, forty-nine years of age, who was in the habit of titillating the epiglottis and posterior part of the pharynx with a tooth-brush, which seems to have had a holder easily detached. On one of these occasions she swallowed the brush. About ten months after this occurrence an abscess formed over the region of the stomach, which burst, and allowed the pointed end of the brush to protrude. It seems that the attendant removed about a centimetre of the foreign body and allowed the wound to heal up, with still an uncomfortable feeling about the stomach. About thirteen years after another swelling and abscess formed in the region of the umbilicus, where the foreign body could be felt. After the abscess discharged, a fistula was formed, through which the brush was extracted, leaving an opening direct into the stomach, from which was emitted odorless gas, while the secretions were acid. In five weeks the fistula opening healed up.—*Med. Press.*

MUMMIFICATION: ONE OF THE RESULTS OF RETENTION OF A DEAD FŒTUS IN UTERO.[1]

By JOHN S. ELY, M.D.,
NEW YORK.

Since careful study began to be accorded to the various phenomena of abortion, death of the fœtus has been regarded the most frequent factor in its causation. So constant is the association of fœtal death and expulsion of the contents of the uterus, that in early times it was customary to look upon the retention of a dead fœtus as evidence of witchcraft, or of Divine displeasure; and superstitious fear prevented the careful investigation of such cases when they occurred. For about three centuries, however, allusions to the remarkable changes in the fœtus consequent upon its retention in utero are to be found in the literature of the subject and have excited the curiosity of medical men the world over. Lithopædia, being the most remarkable of these changed products of conception, were naturally the first to receive description. The study of the process of mummification is of comparatively recent date.

The specimens which I have to present this evening are fœtuses of about four months growth, which were retained in utero for some time after their death, and which have undergone mummification in varying degrees.

I. The first occurred in the practice of Dr. James J. Healy, of Newburyport, Mass., by whom it has been presented to the Museum of the College of Physicians and Surgeons (No. 867). The mother, a primipara, passed through her pregnancy to term without untoward symptoms. During labor digital examination disclosed a hard, sharp body, which, to use Dr. Healy's words, "felt like an oyster-shell coming down with the head of a full-grown and well-developed child, the convexity of the head fitting the concavity of the shell, which proved to be the head of the fœtus." The body of the fœtus is so flat that it was designated by Dr. Healy a "pancake fœtus." The head is flattened from side to side, concave on the right, convex on the left, and is turned so as to look almost directly backward. The trunk is flattened obliquely antero-posteriorly, and is at the same time twisted, so that the flattened pelvis lies in a plane almost vertical to the plane of the thorax. The posterior surface of the trunk is concave, the anterior surface convex. The left arm is drawn backward, the right lies across the front of the trunk. The lower extremities are flat, bent at the knees and ankles, and are twisted. The umbilical cord is very small, but not twisted. The placenta is unfortunately not preserved. The above drawing gives some idea of the distortion of this fœtus. I am inclined to attribute the extreme flattening in this case to compression of the mummified fœtus by the living twin in the genital passage during delivery.

Outline Drawing of "Pancake Fœtus." Front View.

II. The second specimen is in the collection recently donated by St. Luke's Hospital to the College of Physicians and Surgeons (No. 868). It is unaccompanied by any history, but from its appearance I am led to believe the conception in this case to have been single, not twin, as in the first case. Mummification has not progressed as far, and the body is not much flattened. The cord is very much twisted. Examination of the placenta shows it to be very fatty, and the label on the jar informs us that this was attributable to syphilis.

III. The third example of mummified fœtus is from the Museum of the College of Physicians and Surgeons (No. 358). It resembles the others closely in its shrivelled appearance, but shows in addition the deformity of double hare-lip. The thread-like umbilical cord twists around the neck of the fœtus.

The curious shrivelled appearance of these mummified fœtuses cannot fail to excite curiosity as to the nature and mode of production of such a remarkable change. While its complete explanation may be impossible with our present knowledge, still a number of more or less suggestive facts which seem to bear upon it, are at our disposal, and to some of them I shall ask your attention for a few moments.

It is clear that there can be no mummification of the fœtus unless it die and be retained without undergoing putrefaction, and it is hardly to be supposed that such pronounced change in the physical characters of the tissues should occur without concomitant alteration in their chemical composition.

It is quite unnecessary for our purposes to enter into lengthy discussion of the causes of fœtal death—these have received much attention in the various text-books of obstetrics. A word, however, regarding the time at which the death of the fœtus most frequently occurs may not be out of place, for the similarity in age of the specimens presented can hardly have escaped notice, and may have suggested the question as to whether the age at which fœtal death occurs may not have a determining influence on the production of mummification. I am inclined to answer this question in the negative, for although mummification is more frequent in fœtuses of about four months' growth, so is fœtal death, as is shown by careful statistics of abortion, more than half of all abortions occurring during the fourth month. What the influences causing death of the fœtus during the fourth month are it is difficult to say. The growth of the embryo at that time is very rapid, its dependence for nutrition has recently come to be entirely upon the placenta, which during the third month replaces the chorionic villi, and, furthermore, inherited constitutional vices have had time to develop and produce their destructive effects. There is every reason to believe the incubation period of disease to be the same, whether its victim be still in utero or older, and one would hardly expect the effects of a disease so insidious as syphilis (the cause *par excellence* of fœtal death) till after the lapse of several months.

But why should the uterus at times retain a dead fœtus when it is usually so prompt in its expulsion? That much obscurity should surround the solution of this problem is not remarkable, considering our absolute inability to offer any satisfactory explanation of the remarkable regularity of the onset of labor at the expiration of ten lunar months of pregnancy. But are we not apt to overestimate the rarity of retention of what may be called foreign bodies in the cavity of the uterus? We not infrequently see retention without expulsive effort of portions of after-birth, of moles of various kinds and of polypi and submucous fibroids. This suggests ability on the part of the uterus to accustom itself to gradual changes in its contents, even though they may be abnormal. We should accordingly expect to have retention of a dead fœtus more often in cases where the causes of its death had worked insidiously, gradually bringing about its destruction. Among such may be mentioned disease of the placental vessels, faulty development of the fœtus, debilitated state of the mother's health, etc., causes acting to disturb the nutrition of the fœtus. Again it should be remembered that many of these processes insidiously affecting the nutrition of the child are apt to lower the vitality of the mother and render her more liable to uterine inertia.

In twin conceptions the retention of a dead fœtus until the completed development of the living child appears to be one of those conservative efforts so frequent throughout the animal kingdom, and may be regarded as a survival

[1] Paper read at the meeting of the New York Pathological Society, November 13, 1889.

of one of the necessary efforts on the part of our remote ancestors (whose conceptions were habitually multiple) at preservation of the race, so important a factor in its evolution. The importance of this conservative process is strikingly brought out by comparison of the statistics, for mummification is shown to be about three times as frequent in twin pregnancies as in single.

In connection with the discussion of this problem of the retention of a dead fœtus it is interesting to note the frequent observation of a strong tendency on the part of the uterus to discharge its mummified contents at term, even though the conception may have been single. This is illustrated by numerous cases on record, perhaps the most interesting of which is reported by Skjelderup,[1] who observed twice in the same woman retention of a dead fœtus and its discharge at term in both instances.

Long before the discovery of the true nature of the process of putrefaction, non-rupture of the fœtal membranes was held to be essential to the preservation of the dead fœtus, which was then thought to be due to the pickling of the fœtus in the liquor amnii. While not denying the possible influence of immersion in the liquor amnii upon the chemical changes incident to the process of mummification, we are now less inclined to attribute the simple preservation of the fœtus to any action of the liquor amnii than to the exclusion of the putrefactive bacteria which is accomplished by the continuity of the membranes.

And this leads us to inquire into the nature of the chemical changes occurring as a part of the process of mummification. I regret to say that but little is known regarding this subject, and, so far as I am able to find, no analysis of the flesh of a human mummified fœtus has been made. In 1877, however, Forster[2] conducted a careful analysis of the flesh of a mummified calf, which had been retained in utero for about four months after its death, and compared the results obtained with those of the analysis of normal calf's muscle. The accompanying table represents his results:

	Fresh mummified calf's muscle in percentages.	Fresh normal calf's muscle in percentages.
Water	75.3	78.2
Solids	24.7	21.8
Proteids	21.3	20.5
Fats	1.43	1.3
Ash	0.75	1.46

From this it would appear that, contrary to our expectation, there is but very slight variation from the normal in the content of water and solids, that, of the latter, the [illegible] in relative

suddenness of attacks. In Vienna, three-fourths of the population were sick at one time, on which account the name Blitz catarrh (lightning catarrh) was given; while in Delft, during one epidemic, five thousand died. Domestic animals, *e.g.*, dogs, cats, and horses, have always been more or less susceptible to this disease, and various English authorities state that an epidemic is always preceded by a catarrhal fever among horses.

The different epidemics, although resembling one another generally, have, nevertheless, differed so much in some of their chief symptoms, that it might perhaps be interesting to review them hurriedly since 1510, that we may see how certain particular symptoms in previous epidemics compare with the present one.

We will not mention the catarrhal symptoms, as they occurred in all epidemics to a more or less marked extent. Thus we find in the annals of influenza, epidemic of 1510, pain over eye, delirium, gastrodynia, often syncope from seventh to eleventh day, diarrhœa and sweating on the decline; 1557, fever of "double tertian" type, severe pain in side; 1580, epistaxis, vigilance or somnolency, giddiness resembling intoxication, parotid swellings, bilious vomitings; 1658, epistaxis, much cephalalgia, hæmoptysis, dysentery, and followed a few months later by meningitis, etc.; 1675, those of pleuritic fever, bilious

[1] Read before the Medical Society of the Alumni of Charity Hospital, New York, January 14, 1890.

the various other proteid constituents of the muscle were found to be unaltered.

Thus we arrive at the end of our discussion of the subject without being able to draw any very definite conclusion. We have seen that there are reasons for believing the death of the fœtus in cases of mummification to occur gradually, as the result, in most cases, of disturbance of the fœtal nutrition; we have seen that the very insidiousness of the process causing the death of the fœtus in all probability enables the uterus to accommodate itself to the foreign body in its cavity; we have seen the tendency of the uterus to discharge its contents at term persist even in cases where the life of the fœtus has been long extinct; and, finally, we have been led to believe that certain chemical changes, at present little understood, lie at the bottom of the decided change in appearance of the mummified fœtus.

PRESENTATION OF PORTRAITS AT THE MIDDLETON GOLDSMITH LECTURE, ACADEMY OF MEDICINE, JANUARY 15, 1890.

By WILLIAM P. NORTHRUP, M.D.,

NEW YORK.

MR. PRESIDENT, MEMBERS OF THE PATHOLOGICAL SOCIETY AND OF THE PROFESSION: In the early forties, three signs were hung upon three house-fronts of Broadway, in the vicinity of Spring Street.

The sign upon the corner-house read, Dr. L. A. Sayre; three doors below was M. Goldsmith, M.D.; and directly across the street was Dr. John C. Peters.

During a week's visit to Boston, Dr. Goldsmith visited, with a friend, the Society for Medical Improvement, a society combining pathological with clinical studies. On his return home he hastened across the street to Dr. Peters' office, to suggest the formation of such a society in New York.

Meantime young Sayre, having gained favor with the political coroner, who was also an undertaker and had a shop near by, was, with the consent of the coroner, cutting away at all cadavers labelled "drunk," or "drowned," or "stabbed," that found their way to the city's dead-house, located at that time on the corner of Chambers and Centre Streets.

Dr. Peters, the third of this company of young physicians, fresh from study under Rokitansky, was busy translating an early volume of his teacher's work on pathology.

Into such inflammable material then, fell the Boston spark. "Let us form such a society in New York," said Goldsmith. "Make it pathology alone," answered Peters and Sayre. A few older men were consulted on the advisability of starting such a society, but they only wagged their heads and said the like had been tried before.

While our three young men are busy working up their scheme for the first meeting, let us take a hasty look at the medical field about them. In the first place, the City of New York ended at Fourteenth Street. Broadway was paved only as far as Tenth Street. The wealthy families lived about Bowling Green and along Broadway, upon Bond and Bleecker Streets, Park Place, and St. John's Park.

Our young men touched their hats with great deference to the great medical lights, Dr. John A. Swett and Dr. H. D. Bulkley.

Alonzo Clark and Cammann were busy at auscultatory percussion. Willard Parker was a young professor of surgery in the only medical college in New York; Dr. Francis was lecturing on general practice; Dr. Frank Johnson was the great light of the New York Hospital.

Joseph Mather Smith lectured on theory and practice; Delafield on obstetrics, and John Romeyn Beck on materia medica.

In surgery there were great names sounding in the ears of our young men: John Kearney Rogers, Valentine Mott,

John C. Cheeseman, Richard K. Hoffmann, Gurdon Buck, John Watson.

At this time New York had one college, one hospital, and three dispensaries.

Our three young physicians no doubt came, quite late, from Sayre's office, on several evenings, and smelled very strong of tobacco-smoke—but, at any rate, the plans were soon completed for the first meeting, the constitution was drawn up, by-laws written out in full; and the morning mail brought to some of their friends a note asking them to assemble at Sayre's office at four o'clock in the following afternoon, on "special business."

John A. Swett had given the secret away when he said such societies die by the time the constitution and by-laws are framed and the offices distributed.

Our young men had caught the cue, and when Dr. Sayre, at four o'clock, reached out his hand to welcome the first arrivals to the meeting, the elaborate documents, quite complete, protruded from his inner coat pocket. Goldsmith was there, helping entertain the men as they arrived, appearing, no doubt, to wonder what it was all about. At last, bringing up the rear, came Peters, with a most innocent look upon his face, carrying *two huge, mysterious-looking pails*.

The meeting was called to order, and the announcement made that a pathological society was to be formed; a committee was appointed to draft constitution and by-laws, and directed to repair immediately to the rear room. Upon this committee were Sayre and Goldsmith.

The committee estimated that about three cigar-lengths of time would be a fair allowance for a rough draft of such papers, and that, having told the newest stories, they would easily pass the time, and report in good form.

When they finally gathered up their crisp, neatly copied documents, flung open the sliding doors, and sallied forth, expecting to find themselves quite important in the meeting, what did they find? Dr. Peters, still digging among the contents of the two pails, and the whole company gathered about him, scrutinizing his beautiful types of "rum livers," "rum stomachs," perforated intestines, tuberculous lungs, cancerous tumors, etc.

It was getting dark, and lights were brought in. Still Peters dug, and the company stayed. The meeting was prolonged by questions and discussions, and no end of examination of the many wonderful pathological specimens.

As for the report of the committee, it found no opportunity for a hearing for several hours.

Such was the origin of the earliest Pathological Society, and such the success of its first meeting.

It is said that Dr. Swett presided at one meeting, and never came again. The first elected president was Willard Parker.

The meeting just described occurred on June 14, 1844, and there were present: Drs. Goldsmith, Peters, Sayre, Parker, W. C. Roberts, G. A. Sabine, James Crane, Philip Young, Israel Moses, and Macnevin; ten in number.

Dr. Goldsmith is described as "a tall man, considerably over six feet, muscular, and exceeding well proportioned; quick, easy, and graceful, with a handsome, pleasant face; neat, even showy in dress."

To all here present, the physical characteristics of Drs. Sayre and Peters are familiar; and it is not difficult for us to picture to our minds the founders of this Society surprising their friends with "special business" at *four* o'clock: the quiet, enthusiastic, earnest Dr. Peters; the towering, handsome Dr. Goldsmith; the roaring, irresistible Lewis A. Sayre!!

These men said we will organize a society, and forthwith it was started and at once became a success.

We have been looking back forty five years. To-night the old landmarks are mostly gone; the city has overflowed its insular limits; successive groups of great medical and surgical lights have arisen and passed away; medical colleges have grown up, dispensaries multiplied, and New York no longer admits that Philadelphia is the one great medical centre of America.

What has become of our three young enthusiasts in pathological work, the founders of this Society?

A star marks the name of one, upon our membership list. This lectureship—the bequest—memorializes for all time the enduring interest which possessed the mind of Middleton Goldsmith.

Two members survive. We need not ask what marks their interest. Dr. Peters has been for many years—I dare not venture to say how many—twenty, perhaps, or more—editor of the Society's "Transactions." No one here can possibly be made to understand the hours and weeks of time he has put upon that work. For years he has been upon the Committee of Admissions and Ethics. During the term of my service as President, it has been a pleasure and an inspiration to have before me a man who appeared at the earliest gatherings of this Society, has been identified with its workings from that time to the present, who has looked upon and who came in contact with the great men of our profession in a past generation.

To-night, in his son's home on Long Island, too feeble to be present with us, he watches the hours as they pass, and when the time for adjournment of this meeting shall have struck he will say, "This is the first I have ever missed."

Dr. Sayre can remember no early experiences more vividly than those in the early days of the Pathological Society, and can rouse himself from feebleness no more effectually than when he recalls that first meeting and the incidents of the constitution and by-laws. He hoped to meet us here to-night—but he is a cripple, is enfeebled by sickness, and at last broken beneath a sudden and heavy sorrow.

Mr. President, the three portraits before you are gifts from Dr. Sayre, Dr. Peters, and the daughters of Middleton Goldsmith, tokens expressing to you approval and pride in the success and records of the Society of which you are the chief officer. They enjoin upon you the furthering of the good work as best fits and becomes the times and advancement of pathological investigations.

To the Society they stand, and shall stand, as a pleasant greeting, and mutely bid you accept the best wishes of the donors, and God-speed.

In the name of Lewis A. Sayre, John C. Peters, and the daughters of Middleton Goldsmith, I formally present these three portraits, severally, to the corporate body, the New York Pathological Society, to be held as property by its trustees forever.

[illegible] the uterus at times retain a dead fœtus when it is usually so prompt in its expulsion? That much obscurity should surround the solution of this problem is not remarkable, considering our absolute inability to offer any satisfactory explanation of the remarkable regularity of the onset of labor at the expiration of ten lunar months of pregnancy. But are we not apt to overestimate the rarity of retention of what may be called foreign bodies in the cavity of the uterus? We not infrequently see retention without expulsive effort of portions of after-birth, of moles of various kinds and of polypi and submucous fibroids. This suggests ability on the part of the uterus to accustom itself to gradual changes in its contents, even though they may be abnormal. We should accordingly expect to have retention of a dead fœtus more often in cases where the causes of its death had worked insidiously, gradually bringing about its destruction. Among such may be mentioned disease of the placental vessels, faulty development of the fœtus, debilitated state of the mother's health, etc., causes acting to disturb the nutrition of the fœtus. Again it should be remembered that many of these processes insidiously affecting the nutrition of the child are apt to lower the vitality of the mother and render her more liable to uterine inertia.

In twin conceptions the retention of a dead fœtus until the completed development of the living child appears to be one of those conservative efforts so frequent throughout the animal kingdom, and may be regarded as a survival

SOME FEATURES OF THE PREVAILING EPIDEMIC OF INFLUENZA.[1]

By RAMON GUITÉRAS, M.D.,

INSPECTOR HEALTH DEPARTMENT, CITY OF NEW YORK.

Before dwelling especially on particular features of the present epidemic, it would be well, perhaps, to go back a little and consider what the disease in question really is.

It is an epidemic, or, perhaps better, a pandemic which sweeps rapidly over the globe in the direction generally of from east to west, being equally prevalent in all climates, and among all classes of society. It is usually characterized by inflammation of the mucous membrane lining the respiratory tract, in connection with various systemic disturbances.

This disease has more than a score of names, according to the countries through which it passes, the most common of which are influenza and *La Grippe*. Influenza, the generally accepted term, is a name given by the Italian savants of the seventeenth century, because they thought it due to the influence of the stars.

The name, La Grippe, is said to come from the Polish word Crypka, meaning hoarse, but most probably comes from the French word "gripper," to seize, from the suddenness of the attack. It is, however, at present date, with its translation "Grip," by far the most popular one with the masses.

The term, however, which is the most suitable and comprehensive, although it is less used, is epidemic catarrhal fever.

There are many other synonyms for this disease, dependent mainly on its symptoms and locality, such as rheuma epidemicum, cephalalgia contagiosa, Pipp (Pip), Schafhusten (sheep-cough), Huhnerweh (hen-sickness), Blitz catarrh, chinese catarrh, Russian disease, Italian fever, Spanish catarrh, etc.

Brief History.—Epidemics of influenza date back before the Christian era, an outbreak having occurred in the Athenian army in Sicily, B.C. 415. Epidemics after this began to occur at irregular intervals, sweeping over Europe, generally in the direction from east to west, of which no exact and complete records have been kept up to the year 1510, when it prevailed in the British Isles to an alarming extent, and quite an accurate account of the epidemic was written. Various other well-recorded outbreaks followed in the years from 1557 to 1879, about twenty in all, besides many others of minor importance. These varied in severity, in symptoms, in number, and suddenness of attacks. In Vienna, three-fourths of the population were sick at one time, on which account the name Blitz catarrh (lightning catarrh) was given; while in Delft, during one epidemic, five thousand died. Domestic animals, *e.g.*, dogs, cats, and horses, have always been more or less susceptible to this disease, and various English authorities state that an epidemic is always preceded by a catarrhal fever among horses.

The different epidemics, although resembling one another generally, have, nevertheless, differed so much in some of their chief symptoms, that it might perhaps be interesting to review them hurriedly since 1510, that we may see how certain particular symptoms in previous epidemics compare with the present one.

We will not mention the catarrhal symptoms, as they occurred in all epidemics to a more or less marked extent. Thus we find in the annals of influenza, epidemic of 1510, pain over eye, delirium, gastrodynia, often syncope from seventh to eleventh day, diarrhœa and sweating on the decline; 1557, fever of "double tertian" type, severe pain in side; 1580, epistaxis, vigilance or somnolency, giddiness resembling intoxication, parotid swellings, bilious vomitings; 1658, epistaxis, much cephalalgia, hæmoptysis, dysentery, and followed a few months later by meningitis, etc.; 1675, those of pleuritic fever, bilious derangement, etc.; 1710, severe cough, quick pulse, headache; 1729, loss of appetite, rheumatic pains; 1732, bloody discharges from nose, lungs, bowels, occasional swelling of parotid and salivary glands and testes; 1737, biliousness, affection of salivary glands, rheumatism, toothache, hemicrania; 1743, lassitude, shivering, pains in head, back, and limbs, on decline diarrhœa, pustules, and dysentery; 1758, sensation of tracheal excoriation, profuse epistaxis; 1762, headaches, bad cough, pain under sternum, biliousness, crisis by perspiration; 1767, loss of appetite, lassitude, fever; 1775, giddiness, headache, nausea, intestinal disturbances, pain in loins, sides, cramps, prurigo, erysipelas, pustular eruption; 1782, languor, loss of smell and taste, sense of contusion and soreness of limbs and cheeks, pain in chest and sides, delirium; 1803, biliousness and headache, epistaxis, often interchanging with scarlatina or superseding it, low fever subsequent; 1831, headache, loss of taste, soreness behind the sternum; 1837, 1848, and 1879, quite typical.

Etiology.—Predisposing influences, none. People are attacked without distinction of age, sex, occupation, or social standing. Previous or present illness affords no protection. One attack renders no immunity from another. Overcrowded, unhealthy, badly ventilated, and damp dwellings render attacks more severe, although the dwellers are no more prone to it. Influenza may occur at any season. It occurs generally in the autumn, often in the spring, and sometimes in the summer and winter. Latitude has no effect, as in the epidemic of 1837 it appeared at same time in England and Cape Town, that is, in directly opposite zones and seasons. Climate has no effect, as it occurs equally in the dampest and the dryest regions. Foul fogs seem to precede an attack. It is interesting to review the observations made during the foregoing epidemics, concerning certain meteorological signs and coincident phenomena which seemed to have had some influence over the disease; *e.g.*, in 1510, in the annals of influenza, mention is made of blood rain; swarms of locust in Serillas; of caterpillars in Germany; eruption of Hecla; a comet, earthquakes, etc; 1557, foul fogs, eruption of Ætna, comet; 1580, plague of insects and mice, flight of owls; 1675, eruption of Ætna; 1732, volcanic eruption, comet, fetid fog; 1742, comet, stinking fog.

Thus, in almost every case we see some mention of earthquakes, volcanic eruptions, plague of birds or insects, as if they had some direct bearing on the disease. There are at present two views in regard to the point of origin of the disease.

1st. That it starts from some particular but unknown point, and spreads from place to place, until it finally becomes extinct in some region, however distant from its point of origin.

2d. That it may start anywhere, and may have several different points of origin.

Influenza travels at different rates of speed. It takes from six weeks to six months to go through Europe. It generally lasts in a city from one to two months. Large cities are generally affected before villages.

Crews of ships on ocean have been known to suffer from it.

Exciting Cause, Arguments for and against Contagion.—Said not to follow the course of travel; this has not been the case in present epidemic. Closing up the house does not seem to shut out the disease; on the other hand, convents, garrisons, and prisons, which are isolated communities, so to speak, are often not affected.

Families, employees in offices and factories are often ill one after another until all have suffered; on the other hand, only one or two members of a family may be affected. At all events, the rapidity with which it spreads, and the great number who suffer from it at the same time and in the same way, certainly point to some specific poison which is carried by the air as a disseminating medium and excites the disease. This poison was supposed by many, for a long time, to be the sulphur and other matter thrown from volcanoes, which was carried

[1] Read before the Medical Society of the Alumni of Charity Hospital, New York, January 14, 1890.

about in dust-fog currents, a foul fog having been generally noticed before an epidemic, or accompanying it. In this enlightened age, however, I think that we are justified in believing that the exciting cause is a micro-organism. The question then arises, is this disease contagious or infectious, and I think that we can here say probably both. Whether this micro-organism is a telluric emanation, or whether it is the result of some organic change in lower forms of animal or vegetable life; or whether, again, it is due to some morbific principle developing directly in man or higher animal life, in which case it would be considered purely contagious, I am not prepared to say.

In case the micro-organism is developed outside of the body, as it seems most probable that it is, and is carried about in the air, the part of our economy which is first visited by it will be the mucous membrane lining the respiratory tract.

It here excites an inflammation, and probably continues to propagate. The mucous secretion would therefore be impregnated with the germs of disease, and would act as a contagious principle. At the same time, however, it is not reasonable to suppose that the germs contained in the secretions of a patient suffering from the disease are any more virulent than the original ones causing the disease. In regard to the spreading of the disease, it seems most probable that in covering a large distance, such as across an ocean, it would be much more liable to be carried by travellers, baggage, or mail, in other words, direct transportation, than by actual currents. I am a strong believer in aerial contagion, but I also think, when a disease covers a large area, that transportation is a most important factor in its propagation.

The argument that influenza has occurred in two places at the same time, as in Cape Town and London, is of no significance, inasmuch as the disease almost always starts in the East, and if there are aerial currents and transportation which would tend to bring its germs to one point, other currents might have brought them directly in the opposite direction. The question why an epidemic may break out at one time and then for years remain dormant is not an easy one to answer.

It is probable that there are cycles in which peculiar seasons recur, and that such cycles are associated with the reproduction of similar disordered conditions in the health of man. Whether or no these conditions are due to certain changes in lower animal or vegetable matter is difficult to say.

In regard to the present epidemic, we know it started near St. Petersburg in the latter part of October, and reached our shores about the middle of December, that is in about a month and a half after it started, a record which surpasses any previously made. It came directly over the regularly travelled road, which probably accounts for its rapid march.

Notwithstanding that all the bacteriologists in Europe and America are looking for the microbe, none has as yet been found which is generally accepted.

Clinical History.—There is no disease in which the characteristic symptoms vary as much in the different epidemics as they do in influenza, and there is also no disease in which the symptoms vary as much in point of predilection and severity. The severity of the disease depends a great deal on the condition of patient at time of attack, *i.e.*, as to his resisting power; on the amount of exposure to which he has been subjected; and on the character of the epidemic. Almost everyone during an epidemic is attacked, although some suffer to such a slight extent—slight headache, gastric disturbance, or feeling of languor—that they think they have escaped the attack. The varieties of the attack during an epidemic have led to several classifications, depending upon the principal seat of the disturbance, as, for example:

Cephalic, thoracic, abdominal; cerebral, guttural, or bronchial, intestinal, typhoid. This was the classification of Sydenham, and depended upon epidemics extending over three hundred years.

The classification preferred at the present date, however, seems to be that of nervous, catarrhal, gastric.

These varieties, with but few exceptions, have the same general symptoms and tend to conclude in the same way. (The present epidemic is of a "catarrho-nervous," the catarrh being more marked in the lower respiratory tract.)

The general symptoms are: *Onset*, feeling of weakness, faintness, or dizziness, chilly sensations, constipation, frontal headache, perhaps nausea, vomiting, anorexia, languor, high fever.

Acute stage, lasting from a few hours to a week, during which we have frontal headache, often pain in orbits and eyeballs, loss of appetite, strength, and spirits, feeling of languor, lassitude, inability to fix attention, loss of desire to do any mental or physical work; rheumatic pains variously distributed in back of neck, small of back, costal region, and calves of legs; bowels continue constipated; urine high-colored; foul tongue and breath; fever continues of a remittent type, with evening exacerbations.

Stage of prostration, lasting from a few days to three weeks, marked by nervous prostration, general feeling of weakness, especially in legs, sweating on slight exertion, feeling of languor, poor appetite, etc.; and generally a bronchitis of a dry nature.

We will now consider the varieties individually, and point out the especial features of each.

Nervous Variety.—This variety complicates both the gastric and the catarrhal; but when taken immediately is especially marked by severe headache, pain in the eyeballs, rheumatic pains, neuralgia in various localities, restlessness, at times wakefulness, occasionally hyperæsthesia, and following it a stage of great nervous prostration, lassitude, languor, sweating, etc.

Catarrhal Variety.—This is generally spoken of as referable to the respiratory tract, although I presume that the gastric form is catarrhal as well. Several cases have also come under my observation where there seemed to be a catarrh of every mucous membrane, which I will mention in conclusion. The catarrhal form is generally marked by a catarrh beginning in the upper respiratory tract, with pain in frontal sinuses, eyes congested and watery, profuse and watery nasal discharge, feeling of stenosis over bridge of nose, marked angina, occasionally tonsillitis and pain in eyes, tickling in the throat, hoarseness, concluding in a bronchitis lasting from a few days to several weeks. Epistaxis and hæmoptysis occasionally occur.

Gastric Variety, marked by frequent vomiting, loss of appetite, constipation, often severe headaches, angina, and a bright erythematous eruption appearing over feet and upper extremities, closely resembling scarlatina.

The present epidemic seems to differ from previous epidemics in the absence of catarrh of the upper respiratory tract, it being only present in about ten per cent. of the cases. It also differs from many attacks in its mildness and lack of complications. For instance, in present attack, *Epistaxis*, so common in previous attacks, is very rare, only occurring in about two per cent. of the cases which came under my observation. One of these, however, was quite severe, continuing for some twenty hours, and only ceasing on administration of iron and ergot.

Dysentery has also been very rare, occurring only in two cases: one a boy, twelve years of age, lasting twenty four hours and ending in recovery; the other a case of Dr. Paine, who died in thirty-six hours from loss of blood. Blood was also present in the stools of many others in a slight degree.

Hæmoptysis was observed only in a few cases (slight).

Hæmaturia.—Several cases of this complication have been reported by other physicians, although I have seen none personally. It has generally been combined with catarrh of urinary tract, cystitis being almost invariably present.

Glandular enlargements in neck have not been prevalent, probably owing to the absence or mild form of catarrh in the upper and middle respiratory tracts.

Eruptions, with the exception of erythema, herpes, and an occasional urticaria, have been very rare in present epidemic, and no prurigo, erysipelas, or pustular eruptions have occurred.

Follicular Tonsillitis has been observed in several cases complicated with influenza of the catarrhal variety.

Quinsy, complicating many previous epidemics, has not been observed in the present one.

Eustachian catarrh and otitis media are complications which exist in a great many cases of the catarrhal variety, and these are often only particularly noticed by the specialists, general practitioners too often attributing their symptoms to neuralgic pains due to the disease, or to a sense of feeling due to quinine, which is being taken by almost all influenza patients; and thus eruptions of the tympanum have occurred in several cases where paracentesis ought to have been performed.

Diarrhœa.—Several cases have been reported to me where the disease has tended to end in a diarrhœa, sometimes quite obstinate, and in which the stools are frequently tinged with blood.

General catarrhal fever, i.e., a catarrh of all the mucous membranes, was observed in several cases, characterized by high fever, temperature 104° F., rapid pulse, vomiting, diarrhœa, painful and frequent passing of urine of a dark-red color, coryza, laryngitis, slight conjunctivitis, and bronchitis. The attack is very acute, but of short duration.

In children and infants, the symptoms are generally not as marked.

In children, they are as follows: Vomiting, headache, moderate fever, coated tongue, constipation, followed by a bronchitis lasting for almost a week.

In Infants, symptoms of gastro-enteritis, vomiting, diarrhœa, moderate fever, rapid pulse, and occasional convulsive movements.

Sequelæ of Influenza.—I draw my deductions here from the deaths which have been reported to the Health Board as due directly or indirectly to influenza; there have been about one hundred in all. During the heat of the epidemic lobar pneumonia was the most frequent and deadly. At present date, however, lobular pneumonia and bronchitis of the smaller tubes and capillaries are more frequent, and although they are not as fatal comparatively, have nevertheless caused many deaths.

Lobar pneumonia generally attacks patients during the stage of prostration; is frequently double, comes on in almost every case through a chill, and is accompanied by a very high fever. It has occurred most frequently in men, eighty per cent. of whom have been between the ages of forty and fifty-five. Death is usually from heart-failure, and occurs in from two to five days.

Lobular pneumonia is also very acute, lasting from three to seven days. This generally occurs in the old, and middle-aged, and the sickly, although young adults are also frequently affected. It seems to be most common among females. A chill more frequently introduces this disease than the lobar variety in the present epidemic. It begins at bottom of lung and spreads upward; death generally results from heart-failure or asphyxiation.

Capillary bronchitis and bronchitis of smaller tubes are complications of the ordinary form of bronchitis by direct extension. They generally occur in women and at any age. They are very fatal, the great prostration seeming to affect their power of expectoration, so that they choke up and die asphyxiated.

Meningitis has occurred in a number of cases and is very acute, death resulting generally in about two days.

Dysentery has occurred in two cases under my observation. It set in on about the fourth day, and caused death in two days. In both cases the first day's discharges were simply diarrhœal and the second dysenteric.

Nervous prostration, which is such a pronounced symptom in the various stages of influenza, will probably develop into an obstinate sequela, and even now cases of this disease begin to show themselves.

Cholera, a sequela which is so much feared, especially in Europe, will probably never reach our shores; it originates generally in the southwestern part of Asia, where cholera is more or less endemic, and is liable to attack those who have suffered from the gastro-intestinal form of influenza, which often occurs and leaves the mucous membrane in a somewhat denuded condition.

Typhoid fever as a sequela has not been observed in any fatal cases in this city, but the typhoid condition has been noticed frequently, and has been observed especially in some of the cases of dysentery, bronchitis, and bronchopneumonia.

Diagnosis.—The only diseases with which influenza is liable to be confounded are coryza, bronchitis, tonsillitis, dengue, scarlatina, rheumatism.

Acute coryza and bronchitis would be excluded by the absence of severe headache, muscular pains, great prostration, and anorexia, although doubtless, if these occurred during an epidemic, they would be more or less due to it, and most probably mild forms.

Follicular tonsillitis has many symptoms in common with influenza, but would be excluded through the absence of severe frontal headache, rheumatic pains, etc.; although I have every reason to believe that follicular tonsillitis has occurred in several cases of influenza as a complication.

Dengue resembles in a great measure the nervous form of the present epidemic. It would be excluded, however, on account of the different character of its onset, it generally taking from two to three days for the temperature to reach its height; the character of relapse, the pain, swelling in joints, the enlarged glands, the absence of bronchitis, headache, the stiffening of muscles.

The rapidity with which the influenza has travelled and the territory which it has covered, differ also from dengue, which occurs generally in circumscribed areas in the south of the United States, Spain, India, or Africa.

Scarlatina.—This disease, with which the present epidemic has been most confused, is excluded on account of lack of punctate character to the eruption, strawberry tongue, and angina; also, on account of speedy disappearance of eruption, which lasts about twelve hours. The eruption, however, is quite similar in its general erythematous blush, and when it is associated with some angina and high fever the resemblance is quite strong; especially as the tongue shows some enlarged and reddened papillæ on its near tip, which stand out prominently in contrast with the white coating covering it.

Prognosis—Good in most of the cases. The disease is self-limited, and if patient is careful there is no question of speedy recovery. The only danger is when it occurs in the old and the infirm, or those suffering from chronic troubles. One thing noticeable in present epidemic is how few phthisical patients, comparatively speaking, have died from its effects, although in many cases they have succumbed from intercurrent bronchitis. In Bright's disease and valvular disease of heart the influenza is more fatal. A few deaths were due directly to the disease, but these occurred in cases of old age, valvular disease of heart, tumors, and other cachectic conditions, in which the patients died within twelve hours, probably from the shock of the sudden onset. In two other cases of feeble women death occurred in two days, due to heart-failure.

Treatment.—Rest in bed during acute stage. Patient should remain at home until temperature is normal. It would be advisable for patient to remain in the house until entirely well, but as they generally will not do this, it is important that they should remain at home evenings; should be very careful in regard to their clothing, the wearing of rubbers, overshoes, etc.; should avoid all draughts of air, as in the stage of prostration and sweating they are very susceptible to pulmonary complications. They should ride in cabs if possible; if not, in horse cars or the front or rear car of the elevated.

At onset move bowels, calomel two grains every two

hours until they are moved. At bed-time, quinine and Dover's powder with a hot whiskey-punch.

For headache, fever, and muscular and neuralgic pains, give antipyrine, ten grains every two hours, with whiskey, one ounce, until headache is relieved. Two of these powders will generally be sufficient to relieve the most obstinate. It is not advisable to give more than three of them, but, in case they do not work, to change to antifebrin or phenacetin, in five-grain doses every two hours. Whiskey should be given with these drugs, as it hastens their action and tends to counteract their depressing effect. In case the muscular pains are obstinate, salol, five grains, or salicylate of soda, grains fifteen, will generally relieve them.

Great anorexia and weakness being present, milk-punches should be given every two hours, if well borne, during the acute stage.

In all stages of the disease whiskey is the remedy par excellence to counteract the great prostration, and should be taken three times a day throughout the attack. Quinine is also a standard remedy, and is useful both as an antipyretic and a tonic. During the acute stage it should be given, if the stomach can bear it, in five-grain doses three times a day, and in the stage of prostration following it should be given purely as a tonic in three-grain doses, in combination with nux vomica and iron in pill or solution. In the gastric forms, where there is considerable vomiting, good results have followed a milk diet with a powder of bicarbonate of soda, pepsine, and bismuth, ten grains of each every four hours.

In catarrh of upper respiratory tracts a pill of belladonna, camphor, morphine, and quinine every two or three hours gives speedy relief.

In bronchitis of the dry and semi-asthmatic form, which generally occurs, and which seems to be more of a congestion of the bronchial mucous membrane with nervous spasms, a mixture containing belladonna and morphine will usually give relief. When this does not, however, a mixture containing codeia will generally produce the desired effect. In case of bronchitis with abundant secretion, muriate of ammonia or some other stimulating expectorant must be given. In case of angina and tonsillitis being marked, a gargle of chloride of zinc, four grains, in listerine, two drachms, and water, six, generally affords relief. Complications should be treated accordingly, and digitalis should be given in cases where the heart-action is weak, to prevent heart-failure, as influenza seems to have depressing influence on the heart-action.

Clinical Department.

POISONING BY THAPSIA-PLASTER.

By HENRY B. DOUGLASS, M.D.,

NEW YORK.

A PATIENT, suffering from phthisis pulmonalis, developed a new area of consolidation with considerable pleurisy. The new pleural inflammation caused intense constant pain, increased by each movement of the thorax. For the relief of these pains he was given a thapsia-plaster, four by six inches, and applied it to the seat of the pain.

He experienced some relief after hours of application, but in twenty-four hours had developed such alarming symptoms that I was called to attend him. He was naturally a thin man, much emaciated by his disease, but now his face was in strange contrast to its usual condition. The skin over the whole head was severely swollen; the eyelids were so œdematous as to be nearly closed; the scalp, face, and neck were intensely gorged with blood; the skin, superficially œdematous; the arms, chest, abdomen, and back were covered with a confluent eruption of vesicles mingled with a diffuse erythematous condition and a few papules. The pulse was 100, the temperature 99° F., and the respirations 28 per minute. Burning and itching of the skin was intolerable. The only general symptoms were vomiting, and colicky pains in the intestines. The patient was much alarmed by the rapid onset of new symptoms and his rapidly developed uncomfortable condition.

He was ordered to remove the plaster; the whole body was given an alkaline bath; alkalies were administered internally, and in two days the symptoms had subsided.

Thapsia-plaster is a product of the French Pharmacopœia, and, according to Desnoix, is composed of resin, 1,500; elemi, 1,250; yellow wax, 1,800; turpentine, 500; and thapsia-resin, 350. The thapsia garganica in the plaster is the active irritant and one always expects a vesicular or erythematous eruption directly under the plaster, but I have never yet heard of any other case where general eruption followed its application.

There was in this case, no doubt, an irritable skin. But I am inclined to think that when the plaster began to irritate the patient scratched the skin under the plaster, and through his fingers conveyed the drug to other parts of the body by scratching.

The vomiting and colicky pains were the only manifest constitutional symptoms.

As a precaution, it would be well to avoid fingering the plaster and to cover it with a bandage of linen.

TRAUMATIC IRIDODIALYSIS.

By JOHN C. BOWKER, JR., M.D.,

LAWRENCE, MASS.

CASES of the above-mentioned trouble are sufficiently rare to warrant the presentation of the notes of a case recently under the writer's care. The patient, a highly intelligent lad of eight years, was playing with his comrades when he felt something strike his left eye, followed by a sharp pain. He was immediately seen by a physician, who prescribed for him and sent him home. Two days later the father took the case into his own hands and, in examining the eye, found a leaden bullet, weighing eight and a half grains, snugly packed away between the ocular and palpebral conjunctivæ, at the external canthus. This was removed, and when the boy was brought to me there was but a slight conjunctivitis, ciliary injection, and photophobia, together with a rent in the iris, covering probably five or six square millimetres, through which the red reflex was visible. The rupture was at the inferior external quadrant and about two millimetres of the ragged edge of the iris remained along the ciliary margin. The contraction of the iris threw the normal pupil into an irregular oval shape. Vision in the affected eye was 0.6, but through the artificial pupil light alone was distinguishable. The cornea was entirely uninjured and no abrasion could be detected even with a high-power lens. Though the false pupil still exists, the troublesome symptoms have, under treatment, wholly disappeared. The fundus is normal, the capsule seems unaffected, and the lad suffers almost no inconvenience, save from the disfigurement, which is slight.

TRIPLETS WITH ONE PLACENTA.

By R. S. VAN DORN, M.D.,

BASKING RIDGE, N. J.

HAVING noticed in THE MEDICAL RECORD several cases of triplets with but one placenta I add the following, which occurred in my own family, being my wife, and was her first confinement.

Being called from home on business which detained me for several months, I sent my wife to her father's in the country. Receiving a telegram from her that she thought she was about to be confined I hastened to her and found labor had already set in. I made an examination and found as I thought twins. The pains had commenced in the afternoon of November 3, 1889. At about six o'clock A.M. on the 4th, I found, on account of the large size of the child's head, I could not deliver without

forceps, and sent for Dr. P. J. Zeglio to come and bring his forceps. He came, and about ten o'clock we delivered the first child, when he received an urgent call and had to leave me. At six o'clock P.M. I delivered the second child, and at eight o'clock the third one. They were all born dead, and had from all appearances been dead about three or four days. They were all boys and finely developed, and weighed about eight pounds each, the three weighed twenty-four and one-half pounds.

The first was in the L. O. A. position, the second was a brow presentation, and the third a foot presentation. Two of the cords were attached near the border, about two inches apart, the third near the centre of the placenta.

On November 5th vomiting set in but was controlled by bismuth, carbolic acid, ice, and charcoal.

On the 8th I discovered signs of pulmonary œdema, which, under the use of dry cups, diuretics, and tonics passed away. On November 25th I left her to attend to business and returning on December 1st found she was complaining of nausea, headache, thirst, and pain; her temperature was 104° F., pulse 120. Her left lower limb was unnaturally hot and tender, not œdematous, but swollen to twice its natural size, of a pale, white color, tense, and elastic, while it had also a glazed or shining appearance. This I pronounced phlegmasia dolens.

For treatment I used sedative and alkaline fomentations, perfect rest, and simple diet. The fluid in which the fomentation flannels were wrung out was made by adding one pound of bicarbonate of soda and one ounce of extract of poppies to each gallon of boiling water. The flannels were changed every half hour, they were applied over the whole limb and lower part of the abdomen. The result was the pain ceased almost instantly, the swelling began to subside, and now, December 10th, she is on the road to recovery.

Progress of Medical Science.

The Treatment of "Nervousness."—In a paper on this subject, Dr. Zeuner says, among other things, that the general treatment of the nervous system is always essential, usually more so than the treatment of the local trouble, for the nervous disease often disappears while the local trouble remains. On the other hand, the latter may be cured without favorably affecting the nervous manifestations. Hygiene—the proper regulation of the manner of living—is the most important agency in giving tone to the nervous system and removing nervous symptoms. Sleep, diet, out-door exercise, and adequate employment and recreation, are the physician's affair. Hot water, where there is lack of appetite, is often of value. Where there has been overwork, or strain from worry, great responsibility, etc., rest should be ordered. The kind of rest is of moment. A change of activity is often greater rest, both to mind and body, than doing nothing. Inactivity too often favors introspection and brooding, which are to be guarded against as much as possible. Thought must be directed into healthy channels, away from the individual himself, until the proper relations to others are normally adjusted. The first in the list of special therapeutic measures is hydrotherapy, comprising hot, cold, and temperate baths, medicated and mud-baths, wet packs, douches, sponge-baths, etc. Personal trial determines the kind best suited to the case. The simplest form, the sponge-bath, can be administered at home. Hydrotherapy exerts a beneficial influence in nervous cases, partly as a calming agent, quieting the patient, inducing sleep, and relieving pain. Its influence in increasing the heart's action, hastening the circulation, and promoting tissue-changes, is probably greater than its soothing properties. A therapeutic measure of manifold application is electricity. The faradic current is often serviceable. General faradization acts as a tonic, improving the condition of the whole nervous system. Local faradism assists in relieving pain and spasm. The galvanic current, though less commonly employed, has a wider range of usefulness. Central galvanism exerts a general tonic influence, like general faradization. A mild current to the head produces good results, favoring normal sleep, and quieting and giving tone to the nervous system. Static electricity probably has a more limited range of usefulness than the other forms, but it often affords much aid in the management of "nervous" cases. The general application of sparks all over the body is an invigorating process, the static head-bath is calming and favorable to sleep, while more limited applications tend to relieve pain, spasm, and the like. The moral influence of the "big machine" is not to be ignored, patients expressing themselves as great believers in its efficacy. Drugs form the least important element in treatment, and often the patient is better off without medicines. Tonics are most frequently indicated, as quinine, arsenic, strychnia, cod-liver oil, etc. Remedies for the mere relief of symptoms—sleeplessness, excitability—are best omitted altogether. The most valuable of this type are the bromides. Given systematically for a short time, they put the patient in a better condition temporarily, thus allowing other measures to bring about a cure. Severe cases, that induce chronic invalidism, are best treated by the Weir Mitchell plan—rest, massage, electricity, and excessive feeding—when there is loss of flesh and impoverished blood. Change of scene, mountain air, ocean voyages, sea-baths, etc., are powerful adjuvants.

Faradization in Ascites.—Dr. Kaufmann calls attention to this treatment, lately brought forward by Muret, and recommends it from his own experience in ascites, especially where it is due to portal obstruction, as in affections of the liver, spleen, and peritoneum, and in pericarditis. It is less useful where the ascites is part of a general œdema. Its effect is much increased when the treatment is begun by tapping. Then one can readily, with a moderate current, produce energetic contraction of the abdominal muscles, whereas, where there is considerable distention of the walls, even a strong current will not produce effect. Faradization is carried out with the patient lying horizontally on the back and the pelvis elevated. The abdominal muscles are in turn faradized; the electrodes, which are provided with an interrupter, being placed upon the motor points of the muscles. As soon as a moderate contraction is produced, the current is interrupted, and the muscle allowed to relax. This is repeated several times. With regard to the position of the electrodes, the one is placed above the symphysis pubis on the lower end of the rectus (either right or left), the other just below the ensiform cartilage on the upper end of the muscle. For the oblique muscles one electrode is placed underneath the costal margin in the mammillary line, the other upward and forward from the anterior superior spine. For the transversalis the twelfth rib and the iliac crest are the respective positions. The application is repeated several times, and at the conclusion an electrode is placed on the sternum, while the other is set on the different muscles, and by a repeated contraction a form of massage practised. The "sitting" lasts from ten to fifteen minutes, and is carried out once or perhaps twice daily.—*The Practitioner*, October, 1889.

The End not Justifying the Means.—A surgeon in Tennessee is reported in the local press as the hero of the following interesting item: A patient brought his amputated finger to the doctor, who sewed the finger on, being drunk when he did so; the doctor sewed it on with the plain surface turned the wrong way. The doctor, after sobering up, wanted to amputate the finger and put it back right, but the patient declined. The doctor can now be punished whenever the patient points that finger at him.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, January 25, 1890.

THE BALSAM CURE OF PHTHISIS.

THE ingenuity of mind and fertility of resource displayed in discovering new methods of treating phthisis during the passed decade is something remarkable, and it seems as if it must eventually prove successful. At any rate, no failures in the past at all deter enthusiastic workers in this line. It hardly seems possible that another method of treatment, involving a new therapeutic principle, should be devised, yet such is, to a large extent, the case with the Peru-balsam cure as suggested by Landerer, and more perfectly carried out by Dr. Max Opitz (*Mün. med. Wochenschrift*, November 19 and 26, 1889). Landerer based his views of the value of Peru balsam in tuberculosis upon its success in the treatment of surgical forms of this disease. In administering it internally, however, he did so because he thought that the balsam was carried by the blood to the tuberculous areas and there excited an inflammatory action which circumscribed the tubercle, and led finally to its drying up and healing as a cicatrix. The reason why tuberculous deposits do not, as a rule, heal, is because they are not sufficiently vascular, connective-tissue proliferation does not take place, and the ulcerated and disintegrated tissue fails to become encapsuled. The balsam of Peru is thrown into the blood for the purpose of starting up a peripheral hyperæmia and promoting the formation of a capsule. The treatment is not antiseptic, but phlogistic. This theory was tested upon rabbits, inoculated with tubercle. He injected into their veins one per cent. emulsions of Peru balsam, and found that they did cause encapsulation and shrinking of the pulmonary tuberculous nodules. He also tried the treatment upon four men, into whose veins he injected emulsions of Peru balsam of the strength of 1 to 400. Two of these cases, in the first stage of phthisis, were cured; two other patients, in an advanced stage of phthisis, were improved.

Dr. Opitz modified the treatment in this way. He prepared emulsions of Peru balsam of the strength of 1 to 5, viz., powdered gum arabic, 1 gramme; water, 1 gramme; pure Peru balsam, 2 grammes; physiological salt solution (0.75 per cent.), enough to make 10 grammes. This mixture was neutralized with bicarbonate of soda and sterilized by heat at a temperature of 110° C. The preparation, as finally completed, has a white, milky appearance, and shows under the microscope the particles of Peru balsam of about the size of red blood-cells or smaller.

This emulsion is given hypodermically, in the neighborhood of the first or second intercostal space, anteriorly, and the injection is made, with all antiseptic precautions, twice weekly. It is rather painful, but if care is taken no abscess results. The preliminary use of cocaine or ether spray is not considered necessary.

Dr. Opitz divided the cases which he has treated by the balsam emulsions into three groups, corresponding in general with the first, second, and third stages of phthisis. Three patients in the first group were all, at the end of about three months, apparently cured. Those in the remaining groups did not show such marked benefit, though good results followed.

THE INFLUENZA.

WE have received a very large number of communications upon the subject of influenza, to which it is impossible to give space, especially as the epidemic is very rapidly declining and will soon be only a matter of history. The symptoms and course of the disease have offered no special peculiarities, but were such as are recognized generally as characteristic of the affection. There have been the catarrhal symptoms, the headache, pain in the body and limbs, general cutaneous hyperæsthesia, and the strange mental depression so out of proportion to the apparent gravity of the disease.

The tendency to lobar pneumonia, as a complication or sequel of the influenza, was perhaps more than usually marked, though much less marked than one would have supposed from reading the sensational newspaper accounts. These reports undoubtedly did a great deal of harm by exciting the fears of the morbidly nervous and apprehensive, and in disquieting even those of ordinary common-sense. Even if the mortality were not thereby made actually greater, there was certainly much unnecessary mental suffering caused. We did what we could to allay this apprehension in our editorial comments upon the progress of the epidemic, and we were gratified to see that the daily press was ready to accept a professional opinion as authoritative, and by copying so extensively the statements of the MEDICAL RECORD to undo the harm, as far as it could, that some of the more sensational journals had done by their hysterical comments. The mortality from pneumonia has doubtless been high, even for this season of the year, and the increase may very justly be ascribed to the grippe; but when we compare the number of reported deaths from pneumonia with the enormous figures which the morbidity statistics of the influenza epidemic would show (we may safely put the sufferers in this city at nearly half a million), it will be apparent that the danger of contracting pneumonia was by no means alarming.

The only new therapeutic points which have been developed in this epidemic are the good effects obtained by the use of the new synthetic drugs. We cannot see, from the reports furnished us by our numerous correspondents, that any one of these possessed any peculiar advantages over its rivals as far as actual curative effects were concerned; but, as might be expected, the latest and most fashionable was the favorite, and the most loudly praised.

On the whole, we have passed through the epidemic as well as could be expected, and better than was feared by

many who had carefully studied its progress from the extreme east of Europe to our own shores. There has been a good deal of suffering, and many have to mourn for those whose sufferings are past; but there is less of this than there might have been, and, now that the enemy has gone, we may congratulate ourselves that his guns were not so large as we feared they were when we first heard their echoes from a distance.

One word more to our friends of the daily press. There is cholera in Mesopotamia, among the nomad population, but there is no reason in the world why we should take alarm at that. Cholera has existed many times before in the East, but has not necessarily come West. Cholera may come here next summer. New York may be destroyed by an earthquake. We do not believe either event is probable.

THE BUILDING OF NEW HOSPITALS.

According to the *Cincinnati Medical News*, that city has been attacked by a mania for the construction of new hospitals. It mentions among these a hospital by the Episcopalians, one by the Methodists, one by the Presbyterians, a gynecological hospital, and several children's hospitals.

The American Lancet comments upon this, and avers that Cincinnati has already quite enough hospitals. Our esteemed contemporary also deprecates the present mania for building new hospitals, many of these being started to further personal rather than philanthropic aims.

In 1875–76 the medical register for New York City gave a list of twenty-nine hospitals, many of them being small and special in character. In 1889–90 the list includes forty-seven, not taking into account the numerous private institutions or the three homœopathic hospitals. It is evident that the hospital work of this city has doubled in the past fifteen years, although the population is but one-third greater.

A study of the hospital accommodations of Brooklyn shows a similar increase, though proportionately a much smaller number of hospitals, with a population not so very far behind that of New York. Brooklyn has only a dozen hospitals, several of them being special in character.

The increase in hospitals is everywhere greatest in the trading centres, but it is not there alone. Small cities and large towns are all learning the utility of having local hospitals, and throughout the East a hospital soon appears when the local population reaches twelve thousand, or even less. Everywhere the hospital idea is spreading. And the idea is a good one, only it should not be carried too far.

The excessive multiplication of purely charity hospitals has, beyond all doubt, a deleterious influence, not only on the income of the physician, but on the advance of medical science and the *morale* of the patients. It is just as bad to have medical and surgical help extended, and even pressed, upon the public gratuitously, as it would be for the government to distribute largesses of bread and meat. We have passed such a stage of civilization. The present increase of hospitals already has, on the whole, tended to increase the sum total of charitable medical work expended upon those who do not need such charity.

In time this tendency, unless in some way controlled, will prove of manifest detriment to the majority of the profession and to the public. It will lessen the rewards of practice, make the physician's life a harder one, diminish its attractions, and lessen the number of able men who enter it.

It behooves the profession, therefore, to watch carefully this tendency to profuse endowment of unnecessary eleemosynary institutions. *The Lancet* thinks that a solution of the question would take place if the hospitals paid their medical staffs a definite salary, and forbade their private practice, requiring them to give the hospital all their time and energies. Then hospitals would be on an independent basis, and the reasons impelling the construction of new hospitals would not exist; and so the hospitals would follow the laws of supply and demand of the sick rather than the supply and demand of physicians seeking hospital positions.

THE TREATMENT OF LOCOMOTOR ATAXIA BY SUSPENSION.

In *The Practitioner* for November, 1889, Dr. J. Mitchell Clarke reports the results of the suspension treatment in eleven typical cases of locomotor ataxia. He found in this treatment a safe and easily carried out method of treatment which afforded considerable relief to certain symptoms in most cases. Dr. Clarke gives a number of details regarding the technique of the method. Improvement in gait, lessened ataxia, gradual diminution in pains, relief of bladder troubles, partial relief of impotence were among the symptoms noted.

Dr. C. L. Dana, in the *Boston Medical and Surgical Journal* for October 31st, reports twenty-two cases of locomotor ataxia treated by suspension. Among these very marked improvement occurred in four, much improvement in three, slight or no improvement in eleven. The conclusions are in harmony, on the whole, with those of Dr. Clarke, the improvement showing itself mostly in a better gait, greater strength, relief of pain and bladder troubles. The time required to obtain relief varies much. Heavy and helpless patients have to be suspended with great care. Patients in the second stage of the disease, according to Dr. Dana, are best adapted for the suspension treatment.

Messrs. Haushalter and Adam, of Nancy, report the results of their work in this line in *Le Progrès Medical*, November 2, 1889. They have used suspension in 29 cases, mostly of other nervous diseases than locomotor ataxia. In 6 cases of this latter disease they obtained amelioration in 4 cases.

Professor Bernhardt, of Berlin, has tried suspension in twenty-one patients. He finds that the method is applicable to a great number of tabetic patients, whether ataxic or not. Carefully conducted by the physician himself, it is, as a rule, free from danger, and is easily tolerated. But it cannot be denied that accidents may occur. Patients much reduced in general health, also the subjects of heart or lung disease, should not be suspended. Suspension does not appear to cure tabes dorsalis any more than any other treatment, but it may be found to relieve some distressing symptoms, and is, therefore, perfectly justifiable in properly selected cases.

Several other German, French, Italian, and English physicians have contributed to the same subject, but they, for the most part, reach about the same conclusions as those above given, and it may be concluded that the suspension treatment has established itself as a measure of real value in the therapeutics of that chronic and painful disorder, locomotor ataxia.

News of the Week.

Another Alleged Discovery of the Influenza Bacillus.—It is just announced that Professor Weichselbaum, of the University of Vienna, has discovered the bacillus of influenza, and finds in it some similarity to the pneumonia bacillus, but is quite sure that it is a distinctly different microbe. Seiffert, two years ago, reported his discovery of the same bacillus, but his observations were not confirmed. The opportunities for verification of the more recent announcement are more abundant now than then, and we have no doubt that they will be improved accordingly—at least we must wait and see. Microscopic examinations by eminent bacteriologists of Vienna have revealed the presence of numerous micrococci in the sputum, but injections made with this on rabbits only resulted in the death of the animals from septicæmia.

Notes on the Grip. *Mixed Pathology.*—"What do you mean by la grippe, Count, in France? It seems such a strange name for a cold in the head." "Yais, Mees Hartingtonne, eet ees singulaire. I sink ze grippe in America is a sort of—of —vhat you call a handshake—n'est ce pas? And pairhaps zat has somesing to do vith vhat you call ze malair—ze shakes? C'est la même chose, pairhaps."—*Harper's Bazar.*

A Royal Prophylactic.—A report, which is probably a foolish canard, is cabled from London to the effect that the Prince of Wales always wears a sachet filled with frankincense next his skin as a preventive of infection, and attributes his freedom from influenza to its virtue. The Princess of Wales and her daughters wear similar sachets.

The "Grip" in Paris.—At a discussion before the Academy of Medicine Professor Sée stated that the epidemic, in his opinion, was a special form of catarrhal fever. Professor Potain made measurements of the spleen in patients affected with influenza, and he remarked an augmentation in the size of that organ, a fact tending to prove that the malady is the result of a true infection. One curious circumstance brought to notice is that those addicted to alcohol do not take the disease. The doctors have therefore recommended their patients to use warm alcoholic drinks. Unfortunately, on the strength of this prescription, the public have been indulging in these drinks to such an extent that in three days, including Christmas Day, no less than one thousand five hundred persons were arrested in the streets of Paris for drunkenness. Of this number, at least one thousand two hundred stated, in defence, that they were simply following the treatment prescribed for influenza.

The Late Epidemic has made the young doctors dance with joy, while the older ones wish they had never been born; and the specialists are a little in doubt, but expect something later from the wreckage.

The Home of the "Grip."—Dr. Edward M. Buckingham, of Boston, sends to the *Boston Medical and Surgical Journal* a letter from Mr. F. E. Rand, formerly of the Caroline Islands, a group lying about six thousand miles southwest of San Francisco. The writer says that in these islands an epidemic closely resembling the present influenza always appears twice a year, in January and August. This disease attacks nearly everybody. How about hay fever there?

The New Diuretic is named Diecretin and not Duretin, as previously stated. It is chemically the theobromium-natrium salicylicum.

Long Island College Hospital.—Dr. Clarence Thwing, formerly interne at the Hospital for Ruptured and Crippled, in this city, has been appointed Attending Orthopedic Surgeon to the out-patient department of the Long Island College Hospital, Brooklyn.

The Farnham Gift to the Academy of Medicine.—The estate of Dr. Farnham has given $10,000 to the library fund of the New York Academy of Medicine.

The Allegheny General Hospital of Pittsburg has now a male instead of a female superintendent. The latter generally make trouble with the medical staff, as in this instance.

The New Park Hospital, Toronto, Canada, is to be enlarged, and will be completed by October 1st.

Unregistered Dentists.—Two unregistered dentists, of this city, who were really barbers, were recently fined $50 each for filling teeth.

Dr. Charles B. Goldsborough, surgeon in charge of the United States Marine Hospital, New Orleans, died January 6th. Dr. Goldsborough entered the service in 1876, and was stationed successively at Washington, Baltimore, Mobile, Chicago, and New Orleans, where he lived.

Philadelphia Hospital.—Dr. George M. Wells, Chief Resident Physician of the Philadelphia Hospital, has resigned.

Deputy Health Commissioner Sanborn has been compelled to resign and give up his position to Dr. Skinner, a friend of Senator Frank Hiscock. Dr. Sanborn has by a long service of eleven years proved himself a very efficient officer, but that has no bearing on his case politically.

Poisons and their Antidotes.—A bill has been introduced in the New Jersey Legislature providing that all poisons sold should not only be duly labelled, but also name the antidote for said poison.

Trying to Collect their Bills.—Some four hundred physicians of Brooklyn are said to have formed a protective association, the object of which is to protect its members from imposition by supplying for their private use the names of such persons as are ascertained to be able but who will not pay the bills rendered them for medical or surgical aid, and to aid its members in the collection of such bills as are not collectable by the ordinary methods. The report further states that the aggregate of bad bills turned in by the members during the first month was $32,000, and the number of delinquent debtors was about one thousand four hundred.

A Wonderful Operation.—The following report of a most hazardous operation, most skilfully performed, is taken from a secular journal in a neighboring city: "The patient was a man, sixty-eight years of age, and the surgeons removed a tuberculous tumor from his neck. The operation was completed in less than an hour. An incision was made on the right side of the neck, in the submaxillary region, and all of the tumor, excepting the sac, which was firmly attached to the surrounding tissue, was removed. As the tumor had been resting on the internal laryngeal nerve, the patient had great difficulty in breathing. The operation was successful." We wonder if this is the only one of its kind on record? Where is the man who can remove a wen successfully?

No Autopsies at the Chambers Street Hospital.—The New York Hospital authorities have made a rule that no autopsies shall be made at the Chambers Street Hospital except at the request of the coroner. The hospital was censured last fall for permitting autopsies to be made without permission of the friends of the dead person.

Can a Negro Sneeze? is a question which has been ably discussed in the daily papers of several cities in the land, and upon which the opinions of many learned physicians have been obtained by the persistent interviewer. We would suggest, as a more important subject of inquiry, and one which has never yet been satisfactorily answered, Can an oyster laugh?

The New St. Peter's Hospital in Brooklyn was formally opened on January 11th by Bishop Loughlin. The new hospital, which cost in the neighborhood of three hundred thousand dollars, is a four-story, basement, and attic building of brick and stone; the façade of the basement, which is above ground, being of stone, and the remaining stories of Philadelphia brick and ornamental terra cotta. It has a frontage of 220 feet on Henry Street. From each end of the main building a wing extends back 92 feet on the side streets, the one on Congress Street being for female patients, and the one on Warren Street for males. The chapel and convent extend 117 feet back of the main building. There is thus an open court between the convent and the two wings in the rear. The stable, boiler-house, and several other supplementary buildings, have a frontage of 91 feet on Warren Street; the laundry building, which is 50 feet in depth, extending 67 feet on Congress Street. Rolled iron beams are used throughout the hospital, the ceilings being of plaster and the floors and trimmings of varnished yellow pine, except in the kitchens, sculleries, lavatories, etc., where the floors are of tile. The main stairs, from the first story to the fourth inclusive, the stairs in each wing from basement to garret, and the principal stairs in the Sisters' House, from basement to top floor, are of iron, as are the hand-rails and steps, and all trimmings and ornaments. Every part of the building is strictly fireproof, and every convenience known to modern sanitary and plumbing science is provided. There are several freight and passenger elevators, and speaking-tubes and call-bells connect every part of the building. Each floor is also provided with two sets of hose, which are attached to the water-pipes ready for use at need. The building is lighted throughout by gas, and is warmed by heated air from the basement. The hospital contains twenty-four wards, providing in all for 260 beds, in addition to accommodations for a number of private patients. The basement of the main building and wings is devoted to the boiler-rooms, kitchens, sculleries, and dining-rooms for the Sisters, etc., each of which is a model of its kind. The drug store, operating-room, parlors, reception-rooms, consulting-rooms, linen-rooms, porters' rooms, and a few wards occupy the main floor. The second, third, and fourth floors contain the hospital wards and private rooms, as before noted; each story being provided with separate kitchens (provided with apparatuses for warming the food prepared below), lavatories and bath-rooms, linen-rooms, and rooms for washing, disinfecting, and refolding of bandages and surgical appliances. The convent occupies the whole of the rear extension of the main building, and is entirely separate from the front portion, although connected with each floor by several doors. The chapel, which has a seating capacity of 400, is situated on the second floor, at the head of the grand staircase. The hospital is under the care of the Sisters of the Poor of St. Francis.

Poisons Must be Labelled.—Several druggists in this city have been arrested for failing to comply with the law which directs that all bottles or packages containing poisonous drugs must be labelled. Several accidents have occurred recently from the swallowing of preparations intended for external use only, and so marked, but with the omission of the poison label.

The Pauper Hospitals of New York.—The New York County Visiting Committee of the State Charities Aid Association, in their annual report on the condition of Bellevue Hospital and other institutions in the department of Charities and Correction, have found, in their visits to the hospitals, asylums, and workhouses, a few things to praise, many to criticise, and some to condemn. Among the faults at Bellevue Hospital the most serious one to which attention is called is that of the food. The Visiting Committee think that the general diet has been only "fair," while the special diet throughout the winter and spring was "so poor as to be practically useless." The report upon the Ninety-ninth Street Hospital is, that the whole aspect of the place is shabby and discreditable to the city, and that the accommodations are in no way adequate to the growing needs of the district. The dispensary of this institution is much cramped for room; many of the applicants have not space to sit down; and in the district bounded by the North River and Central Park, between Fifty-ninth and One Hundred and Thirty-first Streets, there is no other dispensary. The hospital has no operating-room; the operating-table is in the men's ward, close to the beds, with hardly space to pass around it; and the ward, since the removal of the tent, is often much crowded. There is but one bath-room for the whole hospital—patients, doctors, and nurses. At the City Lunatic Asylum, Blackwell's Island, the accumulation and crowding of patients go on. The number on September 1st was 502 in excess of the capacity of the buildings, and a part of this space was occupied by 31 attendants. The minimum number of patients during the year was 1,660, only 17 less than the maximum of the preceding year. The staff of attendants consisted of 175 persons. During the year there were 128 changes in position among the 175. There were 98 resignations—

more than half the whole number—an apparent sign that the doctors and other attendants think the asylum a good place to get away from. The Visiting Committee think that greater attention to their comfort, and some provision for rest and recreation when they are off duty, would be most effective in improving the service of the staff. The institutions on Randall's Island are generally commended in the report in respect of accommodation and management; but, in connection with the Infants' Hospital, the criticism is made that the good young girls who are in training for nurses are not in the least competent to deal with the women who come as mothers of the babies, and most of whom need discipline rather than nursing. The whole institution, the Visiting Committee think, is founded upon a mistaken system, and should be radically changed or totally abolished.

Nearly a Century of Active Life.—Dr. William L. Candee, one of Milwaukee's oldest physicians, died at his residence, 540 Cass Street, last week at the age of ninety-eight years. His death was the result of general debility. Notwithstanding his extreme old age, the doctor retained his faculties and reasoning powers almost to the last. He was a native of New England, being born at Oxford, Conn., June 9, 1791. When a young man he graduated in medicine, and served through the War of 1812 as a surgeon. After practising medicine in the Empire State for many years, Dr. Candee located in Milwaukee in 1852, where he joined a son who had preceded him two years. He made this his home until the time of his death. The deceased was a remarkably well-preserved man, and knew a great deal of the interesting history of the development of this country by actual experience or personal observation. He saw Fulton's first steam-boat in operation, as well as having been a passenger on the first regular railway train run in the United States.

Society of the Alumni of Charity Hospital.—The January meeting of the Society of the Alumni of Charity Hospital was held at Clark's on the evening of the 14th inst. Dr. Ramon Guitéras read a paper entitled "Some Features of the Prevailing Epidemic of Influenza." The paper elicited an animated discussion, and many interesting points were brought out. Dr. Newton, of Montclair, reported the interesting fact that, in several cases of "grip" which had come to his knowledge, complicating pneumonia had undoubtedly started in the deeper parts of the lung and spread to the periphery—a fact which he thought tended to show that the complication was due to direct infection from the bronchi. Dr. Daniel P. Pease read an interesting paper on "The Differential Diagnosis of Variola," which also elicited a very general discussion.

The Late Dr. Isaac E. Taylor.—At the annual meeting of the New York County Medical Association, held January 20, 1890, the following minute, prepared by a special committee consisting of Dr. John Shrady, A. L. Carroll, and John G. Truax, was adopted: "In the death of Isaac E. Taylor this Association laments the loss of a wise counsellor and untiring supporter. While his professional attainments gave him public distinction, his private virtues endeared him to all who were admitted to his intimacy, and his associates, who knew not only his unwavering devotion to the highest interests of scientific medicine, but his unvarying benevolence of disposition and generosity of thought and deed, mourn even more for the loved friend than for the eminent physician.—P. Brynberg Porter, M.D., *Recording Secretary.*"

Leprous Immigrants.—An alarming increase of pauper immigration is reported at St. Vincent, Minn., *via* the Canadian Pacific, from the Allan line of steamers at Montreal. Six cases of leprosy have developed in that county among immigrants, one of which is in the last stages. It is intimated that the steamship companies have been sending undesirable passengers over the boundary at Hallock, Minn., on the supposition that the official force is lower in that vicinity than it is around New York, a supposition which the Kittson County Commissioners ask the customs officers to co-operate with them in correcting.

New York County Medical Association, Annual Meeting.—At this meeting, which was held on the 19th inst., the reports of the executive and other committees were read; also a summary of the work done, and the general condition of the Association, was presented by the Corresponding Secretary. The active membership was reported to have reached four hundred and thirty, the losses being in consequence of deaths and removals from the State. The Treasurer reported the excess of receipts over disbursements as being nearly $600. Committees on condolatory resolutions were appointed in the cases of Drs. John S. Lenahan, Lewis Hall Sayre, and David Clark Cocks. The tellers announced the number of votes cast as ninety-four, and the result of the election as follows: Charles S. Wood, President; George T. Harrison, Vice-President; P. B. Porter, Recording Secretary; A. D. Ruggles, Corresponding and Statistical Secretary; J. H. Hinton, Treasurer; and A. Palmer Dudley, a member of the Executive Committee, to fill vacancy caused by expired term of service. Dr. John Shrady then read a eulogy upon the late Dr. Isaac E. Taylor, after which the meeting adjourned.

The Title of "Doctor" in America.—"It is a curious coincidence," says the London *Medical Press and Circular*, "that at the very moment when the profession in this country is internally agitated in favor of a more general acquisition of the right to use the title of 'doctor,' the leading medical journal in the United States is seriously considering the advisability of altogether dropping the cognomen as a distinctive mode of address for physicians. Indeed, so widely does the feeling in this respect extend in America, that our contemporary, the Medical Record, of New York, goes so far as to express the hope that 'some day there will be founded a society for the abolition of the title of doctor.'"

A New Antipyretic, which is said to combine antirheumatic and analgesic properties, has been introduced under the name of "Phenylurethane," by Professor Giacomini (*Pharm. Zeit.*). It is a compound belonging to the aromatic group, resulting from the combination of aniline with chloro-carbonic ethyl ether. It is a white crystalline powder, which is insoluble in water, but freely soluble in concentrated alcohol. The dose is about seven grains. Its use is not entirely free from danger, judging by the accounts given.

The Eastern Dispensary, New York.—During the past year 61,228 patients visited the dispensary, 76,000 got medicine free of charge, and 106,748 called for consultation and advice. The expenses were $14,666.66. A new building for the dispensary is being erected at Broome and Essex Streets.

Fifty-five Thousand Dollars for the Hospital Association.—The Hospital Saturday and Sunday Association held its annual meeting January 20th, at St. Luke's Hospital. The annual report showed that the collection for 1889 would be about $55,000, an increase of $3,000 over the preceding year. Of this $40,000 is already in the hands of the Treasurer. St. Bartholomew's Church contributed $6,500, the largest sum ever contributed to the Association by one church in a single year. The sum of $290 was collected at the nine boxes put up at elevated railroad stations. These officers were re-elected: President, George MacCulloch Miller; Vice-President, Hyman Blum; Recording Secretary, John S. Bussing; Corresponding Secretary, the Rev. George S. Baker; Treasurer, Charles Lanier; Executive Committee, George MacCulloch Miller, the Rev. George S. Baker, John S. Bussing, Richard H. Derby, M.D., A. G. Agnew, Jacob H. Schiff, George C. Magoun.

Expert Medical Witnesses.—A special meeting of the Medical Society of the County of Kings was held January 14th, for the purpose of considering the following resolutions:

"*Whereas*, The medical expert witness is at the present time held in less repute than formerly, and his opinions have lost much of their force with both judge and jury; and,

"*Whereas*, Such diminished respect for the medical witness tends to injure the profession as a whole and to lessen its influence; and,

"*Whereas*, It seems probable that the status of medical expert testimony may be improved by united and harmonious action of the profession looking toward that end;

"*Resolved*, That it is the sense of this Society that it is derogatory to the best interest of the medical profession for any of its members to occupy in a legal trial the position of medical adviser to counsel, and witness in the case;

"*Resolved*, That it is the sense of this Society that the physicians who are called upon to give evidence in legal cases, with reference to the existing physical condition of patients, should insist, if it be possible, upon meeting in consultation the physicians to be called by the other side, so that there may be a full interchange of views before they testify."

These resolutions were offered at the May meeting by Dr. J. H. Raymond, the Society voting to postpone the consideration of them until a special meeting could be called, and that representatives of the legal profession be invited to be present and participate in the discussion. The question was discussed by Dr. Raymond, Dr. Jerome Walker, Judge Bartlett, Dr. Sidney Allen, Judge Cullen, Dr. R. G. Eccles, Dr. Otto Singin, and Dr. Duncan. The resolution was tabled for future action.

The Late Professor Volkmann left behind him, almost ready for the press, a monograph on "Cancer."

The Sick Paupers of New York.—From the report of the State Board of Charities for this year we learn: The number of inmates of the various charitable, correctional, and reformatory institutions of the State, October 1, 1889, as shown by the returns of their respective officers, was 67,781, as against 64,322, October 1, 1888, as follows: Insane, 15,482; idiotic and feeble-minded, 1,330; epileptic, 584; blind, 657; deaf and dumb, 1,328; orphan and dependent children, 20,949; juvenile offenders and delinquents, 4,765; adult reformatory prisoners, 944; sick and otherwise disabled soldiers and sailors, 973; hospital and infirmary patients, 3,782; adult and aged persons in asylums and homes for the friendless, 7,007; poorhouse and almshouse inmates other than the above classes, 9,980. During the year the various dispensaries and hospitals of the State furnished medical and surgical relief to 443,341 outdoor patients, of whom 26,097 were visited and gratuitously treated at their homes. The various counties and cities also relieved 59,761 outdoor sick and poor in the course of the year, as against 48,950 the preceding year. The expenditures in this direction were $671,671.36, as against $576,515.83 the previous year.

Philadelphia County Medical Society.—At the annual meeting of the Philadelphia County Medical Society, January 16th, the following officers were elected for the ensuing year: President, Dr. W. W. Keen; First Vice-President, Dr. J. B. Roberts; Second Vice-President, Dr. J. H. Musser; Secretary, Dr. S. Solis-Cohen. Delegates were also elected to the American Medical Association, to the Pharmacopœial Convention, and to the Medical Society of the State of Pennsylvania. Following the election, Dr. Keen delivered his annual address, in which he reviewed the work of the Society during the year.

A Mistake.—Our esteemed contemporary, the *Weekly Medical Review*, admits that Chicago physicians assume somewhat more prominence than St. Louis physicians, and thinks that the reason is that the latter "do not write." We believe that it would be a great mistake for the profession of St. Louis to adopt this view, and try to seek prominence by writing. It is not writing, but working, which gains for medical men eminence. Let St. Louis physicians seek to contribute to the solid advancement of the medical sciences, and incidentally, write.

A Convention of Physicians was held in Baltimore on January 2d, for the purpose of preparing a bill to regulate the practice of medicine in Maryland. Such a bill was drawn up and unanimously approved. It provides for the appointment of a Board of Medical Examiners, independent of all colleges.

Post-Graduate Instruction at the Johns Hopkins Hospital.—It is announced that special courses of post-graduate medical instruction will be given in the Johns Hopkins Hospital, physicians residing in the city of Baltimore being admitted free of charge, upon registering and obtaining tickets of admission at the office of the Hospital.

The Greatest Number of Births in England occur in the month of February, and the least number in June. It is in May, therefore, that men's fancies most intensely turn to thoughts of love; while September is the coldest month of the British year.

"Female Medical Men!"—An Irish editor says he can see no earthly reason why women should not be allowed to become medical men.

The Dengue Fever has been epidemic at Smyrna, and has attacked four-fifths of the population of one hundred and fifty thousand.

The City of Atlanta, Ga., has voted to appropriate the sum of $30,000 to establish, the Henry A. Grady Hospital.

The Earl Crematory at Troy, N. Y.—The twelfth crematory erected in this country has just been finished at the Oakwood Cemetery, Troy, N. Y. Two bodies have already been incinerated there.

The Advance Westward of the Cholera.—It is stated that the epidemic of cholera which has for months hung about the Tigris and Euphrates Valleys, and the interior of Mesopotamia, has made considerable inroads into Persia. News of its having crossed the western boundary of that empire has been received from time to time, and it is now announced to the Faculty of Medicine of Paris that there has been an alarming increase of the disease in Central Persia and on the Turco-Persian frontier; and that the inhabitants are fleeing northward.

Dr. William Blake Eager, a leading physician of Middletown, N. Y., died on January 20th, from pneumonia, aged sixty-five. He was graduated from the College of Physicians and Surgeons in 1848, and practised in this city. He was chief of the medical staff at Blackwell's Island for a time, and then held the position of Professor of Gynecology at Bellevue Hospital Medical College. When the war broke out he entered the army as a surgeon. He had resided in Middletown since 1874.

Death from Chloroform due to Respiratory Failure.—A telegram to *The Lancet*, from Dr. Lauder Brunton, now in India, states that, after experiments on four hundred and ninety animals, he has reached the conclusion that the danger of chloroform is asphyxia, not heart failure—a direct reversal of Dr. Brunton's former views.

The Belgian Medical Federation have hit exactly. They have come to the conclusion that the ranks of the profession are overcrowded because a large number of young men of no particular ability, from the artisan and lower classes, have the idea that the practice of medicine is a nice light sort of work. To stop this it is proposed to require, as a preliminary to entering upon medical study, a very complete classical education, with a good knowledge of modern languages.

The Carriage of Infection by Medical Men.—This subject has been much discussed of late in English papers, and aroused several ingenious suggestions: One gentleman (Dr. Eastes) suggests keeping a macintosh hanging in the hall in houses where there is a case of infectious disease, the said garb to be donned on entering the room. The most foolish plan is probably that suggested by Mr. Fussell, the medical officer of health for East Sussex. This gentleman orders a sheet to be placed over the patient's head and face and the windows to be opened for three or four minutes before he enters the room. Failing a glazed macintosh, he wraps himself up in a sheet and pays a hurried visit, with his hat well down over his ears. The effect on the patient of such a ludicrous yet awe-inspiring ceremonial must be singular.

Professor Robert Koch is writing a complete treatise on the biology of the tubercle-bacillus.

For Metrorrhagia.—Hydrastis canadensis as a uterine styptic has been favorably tried by Schwieger and others, in uterine hemorrhages of all classes.

A Connecticut Doctor has just married the woman with the iron jaw. We trust she will not give him the grip!

Professor Damaschino, of Paris, died in that city on December 22d, of pneumonia, following influenza, in the forty-ninth year of his age. He was Professor of Medical Pathology in the Faculty of Medicine of Paris.

Physicians Concealing a Murder.—A young man, living in Westchester County, was recently brutally murdered by a member of a secret order of Irishmen. Members of the order, it is said, secured two physicians who held an autopsy, and reported that "death was due to acute congestion and œdema of the lungs." The names of these physicians are given in the *Times* as Drs. MacNichol and E. A. Williamson. A subsequent autopsy, held by Drs. L. L. Seaman and W. E. Lyon, showed that death was due to gunshot wound of the peritoneum. The jury signed this remarkable verdict, which had been drawn up by Coroner Mathews: "We find that John Rusk came to his death from acute congestion and œdema of the lungs, this verdict being rendered on the evidence of Drs. MacNichol and E. A. Williamson. We, the jurors, having no evidence, from the testimony taken from the witnesses before us, to prove that Thomas Hart shot John Rusk, therefore it is our duty to exonerate the said Thomas Hart from the affair, or of being the cause of John Rusk's death." Coroner Mathews went to White Plains with this verdict to secure the release of Hart, he having surrendered himself when he learned that Rusk's father had sworn out a warrant charging him with his son's murder; but the Sheriff refused to discharge the prisoner upon a Coroner's verdict.

Obituary.

DAVID CLARK COCKS, M.D.,

NEW YORK.

Dr. David Clark Cocks died in this city, on January 14th, from exhaustion, due to a severe attack of influenza. He was born in Newburg, N. Y., September 17, 1851, and came here with his parents when three years old. He was educated in the public schools and in the College of the City of New York, and recieved his medical degree from the Bellevue Hospital Medical College in 1874.

He was a conscientious, hard-working student in the specialty which he had adopted, and rose to be a surgeon in the New York Eye and Ear Infirmary; he was likewise a member of the New York County Medical Association and the New York Academy of Medicine, besides other societies devoted to the cultivation of his department of medicine.

As a practitioner, on the east side of the city, he was well known, and up to the time of his death had a large clientage. Toward the last he became a rather frequent contributor to the literature of his specialty, having read several papers before medical associations, some of which were published. He took considerable interest in tracheotomy, and afterward in intubation of the larynx, his successes being somewhat above the average. In every sense he promised to become a leading man in the profession when death cut short his career.

Society Reports.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 25, 1889.

H. M. Biggs, M.D., Vice-President, in the Chair.

Necrosis of Pancreas.—Dr. H. P. Loomis presented a specimen of "Necrosis of the Pancreas." J. E——, aged forty, of about two hundred and ten pounds in weight, who had been drinking hard for three months, was admitted to Bellevue Hospital, apparently suffering from the effects of his debauch. For two weeks previous to his admission he had a diarrhœa, during which his stools were at times streaked with blood. No history of any previous illness was obtainable.

On admission the patient was mildly delirious. His stools were of a light yellow color, containing small masses of fecal accumulations surrounded by mucus which was streaked with blood. His temperature was normal, and his pulse was rapid but regular. His condition did not warrant a grave prognosis, but seven hours after admission he suddenly went into a state of collapse, and died from heart failure.

The autopsy was made twenty hours after death. The body presented all the appearances of general obesity. The lungs were normal, and the heart appeared normal, although the microscope revealed fatty infiltration of its muscle fibres. The spleen was normal. The liver showed excessive fatty infiltration, and there was moderate degeneration of the epithelial cells of the uriniferous tubes. The intestines, with the exception of congestion of the capillaries in places along the duodenum and ilium, were normal. The pancreas was greatly enlarged, measuring eight inches in length, two and one-half inches in breadth, one and one-eighth inch in thickness, and it weighed twice as much as normal (eight ounces). The pancreatic duct was pervious. Projecting from the surface, and better seen on opening the organ, were greenish-white areas, varying from the size of a pin's head to that of a large olive. The large areas presented a gangrenous appearance, but were dense and contained no fluid. Between these necrotic-looking areas the substance of the pancreas appeared normal.

Microscopical examination showed that the gangrenous-looking masses were areas of coagulation necrosis surrounded by normal tissue. In some of the areas faint outlines of the pancreatic tissue could be made out; in other areas were seen coagulated fibrin and some granular material. From an examination of a number of sections, the most probable explanation of the cause of the necrotic masses in the pancreas was that they were the result of previous hemorrhages into the substance of the organ.

Acute Broncho-pneumonia, with Obscure Symptoms.—Dr. L. Emmet Holt presented specimens from a case of "Acute Broncho-pneumonia, with Obscure Symptoms and Late Development of Physical Signs." The patient, an inmate of the New York Infant Asylum, was a female child, fifteen months old, and died in the seventeenth day of the disease.

During the first week, with a steadily high temperature reaching nearly 105° F. every day, the respirations were only 40 per minute; there was no cough, and repeated examinations of the chest revealed no signs of disease. In the second week the respirations rose to 70 per minute, and varied between 50 and 70 until death. There were now present a few fine râles over both lungs posteriorly, but never any signs of consolidation.

There was mild diarrhœa throughout the disease.

The autopsy showed small spots of broncho-pneumonia widely diffused throughout both lungs, but no large areas of complete consolidation. In the anterior border of the left upper lobe was an area, about the size of a hen's egg, completely hepatized and resembling in gross appearance lobar pneumonia. In this were one or two small abscesses one-quarter inch in diameter, and a small, wedge-shaped spot of gangrene, with the base at the surface of the lung. This communicated with a small bronchus, but no obstruction could be discovered either in the bronchus or pulmonary vessels. The intestines showed moderate colitis, other organs essentially normal.

The principal interest of the case lay in some of its clinical features.

First, a steadily high temperature, due evidently to pneumonia, the respirations being scarcely above the normal for a week. Secondly, the late appearance of physical signs and their meagreness.

A Small Spleen.—Dr. H. S. Stearns presented "A Minute Spleen," removed from the body of a man, aged forty-six, who had died from pulmonary tuberculosis. He was of large size, and had been apparently well nourished. He had suffered from malarial attacks for several years. The spleen was of very small size, measuring only 6.75 c.m. in length by 2.5 c.m. in width and 0.66 c.m. in thickness, and weighing but 5.92 grammes.

A Grape-seed in the Vermiform Appendix.—Dr. H. M. Biggs showed "A Grape-seed in the Vermiform Appendix." The appendix contained a small fecal accretion, in the centre of which was found a grape-seed. It was very rare in his experience to find any nucleus in these fecal masses lodging in the appendix.

Typhoid Fever without Enlargement of the Mesenteric Glands.—Dr. Biggs also presented specimens from a case of the above. The patient had been sick, with a temperature running from 104° to 105° F. At the autopsy general peritonitis was found, with perforation of the intestine. There were numbers of very small ulcers just above the ileo-cæcal valve. The mesenteric glands, however, were not enlarged at all. The spleen also was not enlarged, its weight being about one hundred grammes. The case was, nevertheless, undoubtedly one of typhoid fever.

Incomplete Ventricular Septum was a third specimen discovered at the autopsy of a woman, aged thirty eight, who had died of pulmonary tuberculosis. There was one large opening, about one centimetre in diameter, and in addition a number of small ones. As far as could be learned there had been no symptoms of this condition noted during life.

Injury of Larynx from Electric Light Wire.—The last specimen was one showing "Injury of the Larynx from an Electric Light Wire." The man from whom the specimen was taken was a lineman who had been killed by electricity while repairing some wires on a telegraph pole. One of the wires had come in contact with the face, and sliding down to the mouth had cut into the cheeks. The other had opened the larynx, cutting through the thyroid cartilage and the upper portion of the cricoid, and producing almost complete occlusion of the larynx. At the autopsy of this man, and of others dying from electric shock, the blood was found to be dark and fluid, no clots being found anywhere in the body. Minute hemorrhages were found under the surface of the various serous membranes, and, in addition, there was general congestion of the viscera.

Dr. Roosevelt said that he had seen many cases of perforation of the vermiform appendix, but had never seen any in which there was anything present except fecal matter.

Dr. Biggs said that this was the third case in which he had found a foreign body as a nucleus of the fecal mass in the appendix. In the first there was a raisin-stem, and in the second an apple-seed.

Dr. M. Putnam-Jacobi asked whether in these cases of foreign body in the vermiform appendix there were any peritoneal adhesions drawing open the lumen of the appendix and thus allowing the body to enter.

Dr. Biggs replied that he had seen numerous cases of concretion in the appendix, in which that portion was perfectly normal and where no peritonitis was present.

The Society then went into executive session.

Stated Meeting, November 13, 1889.

WILLIAM P. NORTHRUP, M.D., PRESIDENT, IN THE CHAIR.

Tuberculosis of Various Organs, and Cancer of Stomach.—DR. H. M. BIGGS presented some specimens showing "Tuberculosis of Various Organs and Carcinoma of the Stomach." The patient died from what was supposed to be, and what proved to be, cancer of the stomach. There had been pus in the urine, and there had also been symptoms of vesical trouble, but the exact nature of this disease had not been determined. At the autopsy there was found to be carcinoma of the stomach, the new-growth nearly encircling the pylorus. On removing the right kidney the pelvis and ureter were found to be greatly dilated, and in the lower portion of the kidney was a large cheesy mass, evidently tuberculous in its nature. In the left kidney a similar condition was found, though the lesions seemed to be somewhat more advanced than on the other side. There was greater dilatation of both the pelvis of the kidney and of the ureter on this side. In the bladder was a very large tuberculous ulcer, the size of two silver dollars, which had perforated the wall of the bladder. Around the urethral orifice and at the trigonum were several tuberculous abscesses, and the prostate contained a very large abscess. The lungs did not show any marked tuberculous process. There was pronounced anthracosis in both upper lobes, with an enormous increase in connective tissue, and scattered through both upper lobes, and, to a certain extent, in the lower lobes as well, were small groups of fibroid tubercles. In the intestines, also, were a number of tuberculous ulcers, which were interesting because of the fact that they completely encircled the intestinal wall, and at a number of points had produced considerable stricture of the intestine. This, in the speaker's experience, was an occurrence of considerable rarity.

It is very difficult in these cases, Dr. Biggs said, to determine which is the primary process. In the case here shown there may have been a cheesy process in the lungs from which the disease started, although the appearance of the lesions would seem to point to the genito-urinary tract as the part primarily affected. The combination here shown of general tuberculous lesions and of carcinoma was a very uncommon one.

Syphilitic Disease of the Skull.—Dr. Biggs then presented a second specimen, showing "Syphilitic Disease of the Skull." There was marked thickening of the skull, and an enormously thickened pericranium, and beneath this was a carious process going on. The bone seemed, at first sight, to be hard, but it was not, as the saw cut into it very easily. The skull was asymmetrical. Thickening of the skull from syphilis was not at all common in the speaker's experience. The pericranium in this instance was nearly three-sixteenths of an inch in thickness. There had been no cerebral symptoms at all. The patient had died from acute lobar pneumonia.

The Question of Primary Tuberculosis in the Genito-urinary Tract.—THE PRESIDENT asked the speaker what his opinion was as to the frequency of primary tuberculosis of the genito-urinary tract.

DR. BIGGS replied that it was very difficult in such cases to determine whether the primary process is in the lungs or in the genito-urinary tract, because it is almost impossible to form any conception as to the age of tubercular lesions; there is such a marked tendency sometimes for the process to remain stationary for long periods. There may be a few cheesy masses in the lungs which may remain there with little or no change for years, and yet these may be foci from which are started up, later, extensive tubercular processes in other organs. In the case here shown there may have been some localized tubercular process in the lung which was primary, although the appearance of the lesions, regarding both the extent and apparent duration, would seem to point to the genito-urinary tract as the part primarily affected.

He had long felt that in such cases the probability was largely in favor of the primary process being located in the lungs, and of its forming a focus for secondary deposits in the genito-urinary tract. It was possible to explain development in the genito-urinary tract, then, on the supposition that the tubercle bacilli, having in some way made their way into the circulation, were excreted by the kidneys, and in the process of excretion a local tubercular process was set up either in the kidneys or in some portion of the urinary tract. It is known that after the injection of pyogenic organisms into the blood, they are thrown out in the urine through the kidneys, and foci of suppuration are thus produced in the kidneys, and it seems not improbable that tubercular foci may be produced in the same way. The speaker had never seen a case of genito-urinary tuberculosis without tubercular lesions in other organs, and, although he had formerly regarded some of these cases as primary there, he had now come to consider them as probably secondary, certainly this was usually the case.

It was possible to explain genito-urinary tuberculosis in the female on the supposition that it was transmitted from the male during coitus, where there was tuberculosis of the male genital tract; but this explanation would not account for the development in the male genital tract. A German observer had shown, however, that in advanced primary tuberculosis, where there were no visible tuberculous lesions in the testicles, there might yet be isolated tubercle bacilli there.

DR. JOHN S. ELY said that Dr. Biggs had mentioned the attempt of the kidneys to excrete the bacilli in the blood, but he had not shown clearly how these organs became infected during that process. The speaker believed that the proneness of these organs to infection could be accounted for in a measure by the fact that the capillaries here and in the glands generally were very fine. In passing through these capillaries the bacilli would run a much greater chance of being caught, and, as a result of such detention, tuberculosis would be set up. During secretion, also, there is an increased amount of blood in the parts, and this offers a further explanation of the greater liability to infection, since with the increased volume of blood there would be a greater number of bacilli brought to the kidneys, and thus the chances of some of them being caught would be correspondingly increased.

THE PRESIDENT said that in his autopsies on tuberculous children he had found the lungs most markedly affected in the vast majority of cases, the bronchial glands being also involved. When the lungs were seen to be pretty well sprinkled with tubercles it was his custom to look at the liver and then at the spleen, these two organs being affected with about uniform frequency. When the disease was very extensive, involving perhaps the peritoneum or mesenteric glands in addition to the liver and spleen, he would then look to the condition of the kidneys with some expectation of finding them diseased. But he would not expect to find these organs affected until the tuberculous tide had risen so high as to engulf almost the entire body.

DR. FISHER asked whether any endarteritis of the cerebral vessels was found in the case of syphilis of the skull. In looking up the subject of cerebral syphilis sometime ago he had seen the statement that when other organs were particularly affected the brain was apt to escape.

DR. BIGGS said that there were some endarteritis present.

Mummified Fœtuses.—DR. JOHN S. ELY presented a number of mummified fœtuses, and read a paper on "Mummification." (See p. 90.)

DR. BIGGS asked whether there was any difference between the mummification of a fœtus within the uterus and that occurring in extra-uterine pregnancy.

DR. ELY replied that there was no reason to suppose that there was any difference at the beginning, but calcification was much more common in extra-uterine pregnancy. In answer to a question concerning the significance of the table presented, he said that he thought it

was of but little importance except that it showed that there was some chemical change in the process of mummification. But what the exact nature of the process was he was unable to say.

Round-cell Sarcoma of Brain.—Dr. H. S. Stearns presented a specimen, and a plaster cast made from it by Dr. Byron, of a small "Round-cell Sarcoma of the Brain." The only symptoms that the patient had had were a loss of eyesight and an affection of speech. He could only repeat words, and if asked a question he would simply repeat that and not give an intelligent answer. The tumor was lying on both frontal lobes, about two thirds on the left and one-third on the right. The patient was forty-seven years of age.

Dr. Fisher said that it was impossible, from a simple inspection of the specimen, or of the plaster cast made from it, to tell how much of the brain substance was involved. Apparently the first and second frontal convolutions on both sides were encroached upon. He could not understand how the speech could be affected by a tumor in this situation, except as the result of intra-cranial pressure. The blindness, also, could have been caused only by the general pressure and not directly by the tumor itself.

Dr. Linsley said that he would like to ask the Society if any of the members had ever seen unstriated muscular tissue in a tumor of the brain. At an autopsy recently made at the Presbyterian Hospital a fibro-sarcoma of the brain was found which contained something that had every appearance of unstriped muscular tissue. It was seen by several pathologists, and they all remarked upon the peculiar appearance of the tissue, but were unable to define its true nature.

The Society then went into executive session.

Correspondence.

A PLEA FOR MEDICAL WOMEN.

To the Editor of the Medical Record.

Sir: In a recent editorial in the *Medical News*, on co-education in colleges, the writer strays from his subject to that of hospitals, and describes with horror a case where a young man and woman, medical students, together watched for several hours by the bedside of a woman in labor. It seems the writer has not reflected that, even if the woman student had not been there, the female patient would have remained, and probably also the female nurse. How, then, would an "association of the sexes" have been avoided? How is it ever avoided when the patient is a woman, and presumably sensitive in regard to a hundred details which become entirely forgotten by a medical student?

The coarse remarks which are so frequently made on this subject always overlook the fact that in America the entire movement to reintroduce women into medicine originated in a reaction against the invasion of midwifery by men, and in a desire to save the feelings of female patients, too often wounded in the searching manœuvres of modern medical practice. The first medical school for women was founded in Boston by Mr. Gregory, exactly because his sense of delicacy and decency and propriety had been outraged by the idea of male practitioners waiting at the bedsides of women in labor. The crusade upon which he engaged forty-five years ago is now nearly forgotten.

His energetic denunciations of the indecency and immorality of *men*, in medicine, would now generally provoke a tolerant smile rather than an argument. But it is interesting to see how exactly they resemble and balance the similar denunciations which are still made, and with not a hundredth part the justification, of *women* in medicine practising for their own sex.

The writers upon "men midwives" greatly exaggerated and distorted a situation in which there was, nevertheless, a certain basis of fact for their protests. The writers upon women medical students often wilfully pervert the description of a situation by statements which they cannot but know to be entirely false. They know perfectly well that what women students desire and claim is the full opportunity—still largely denied them—to qualify themselves to practise among women and children. They choose to pretend that this cannot be done without indecorum, *because*, to certain male clinics, and to one or two lectures out of a medical course, it would be indecorous, and therefore undesirable, to admit women—and where women students would not, in the least, desire to go. Surely this is most disingenuous! And all the more because the discussion on decorum deliberately thrusts out of sight the serious difficulties in the way of decorum actually encountered (and overcome) in the daily practice of medicine among women, by men physicians.

I repeat, wherever there is a female patient there can be no impropriety in the presence of a female student or physician. The real difficulty lies on the other side, and though I fully admit that it is in the interest of everyone that this difficulty should be overcome; that men physicians should attend women when necessary, in all kinds of cases, and that a popular outcry on such a subject can only do harm, and intensify both physical and moral suffering—yet it should also be recognized that such modern prerogative is a purely intellectual necessity; that the "moral" and "æsthetic" conditions upon which writers lay stress all tend toward the exclusive employment of women. For men to invoke these, therefore, is, logically, suicidal.

A writer who will misquote from an article printed in the same issue of his own paper, as unintelligently as the editor of the *Medical News* has done in this editorial, cannot perhaps be expected to be more accurate in regard to wider issues.

Mary Putnam-Jacobi, M.D.
110 West Thirty-fourth Street, New York.

New Instruments.

A SELF-RETAINING NASAL SPECULUM.

By L. L. Palmer, M.D.,
Toronto, Ont.

My only excuse for adding to the armamentarium is that my confrères on rhinological operations may, if they wish, be possessed of a speculum that answers indications that are not answered by any other that I have seen, and will neither fail nor annoy them in the midst of an operation.

It consists of a modification of an eye speculum, and when introduced stands from the nostril upward over the nose.

Its grip is just within the muscular rim of the naris, not reaching up to the tender mucous membrane, nor to the cartilage, and therefore is easy for the patient while it dilates to the utmost.

By its position and shape the upper part or ring may be held by the thumb and finger of the left hand, and the point of the nose raised and turned to right or left, giving a full and perfect view of interior. The advantage of this will be appreciated by the operator, who has so often found his finger besmeared with blood and secretion. I have a leather band to put around the head, with which, and a cord and hook attached to the upper part of the speculum, the point of the nose may be raised and held in position, thus giving freedom to both hands.

This speculum, when once in position, will remain till it is removed; it will not fly out.

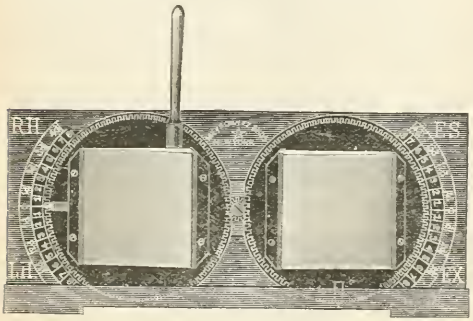
For ordinary and frequent examinations Bosworth's speculum, or some modification of it, may be found more convenient and easy of adjustment, but for operations I find this one a continual satisfaction.

A NEW SLIDE WITH ROTATING PRISMS FOR THE PHOROMETER.

By GEORGE T. STEVENS, M.D.,

NEW YORK.

In the description of the phorometer published in the Medical Record, May 5, 1888, two slides carrying prisms were described. One of these slides carried "two prisms placed horizontally with their bases in and of sufficient strength to induce homonymous diplopia." The other slide carried a single prism with its base down. In testing the eye-muscles for deviating tendencies from the horizontal plane (hyperphoria), the slide with two prisms was used, and any deviation of the images from the horizontal plane was to be corrected by prisms from the case



of trial-glasses, the strength of the prism required for this purpose determining the degree of the deviating tendency.

In like manner, with the single-prism slide, lateral deviating tendencies were to be determined.

Great as were the advantages of the phorometer, with these slides, over other methods previously employed, it was soon found that the instrument could be much improved by the use of rotating prisms, one slide of which would serve the purpose of both of those at first used.

During the whole of the past year I have used such a slide and have found it extremely convenient, and that it can be used with greater expedition and with greater assistance in the search for the extent of deviating tendencies. By making a gradually increasing correction a more accurate result can be obtained than when prisms of different strengths are made to replace each other, a process which permits the muscles time to regain the excessive tension which may have been, for a moment, surrendered.

The slide as now used is represented in the accompanying figure. It contains two cells, in each of which rotates a disk, each disk carrying a prism of 4°. Each disk is furnished with a border of teeth or cogs. A small gear-wheel placed between the two disks communicates the movements from one disk to the other.

Around the outer part of the border of each cell is a narrow raised band on which is marked a scale of degrees increasing from the centre each way from 0° to 8°, the numbers representing the refracting *angle* of prism, the method of notation now commonly used. A second scale, just outside the first, is similarly graduated according to the new system of designating prisms by the refracting *power* or number of degrees of minimum deviation. This scale is made to correspond to the standard recommended by Dr. Jackson and others to the American Ophthalmological Society at its session in 1888. The numbers in this scale are marked 1°d, 2°d, etc. (The engraving fails to reproduce the numbering or the corresponding spaces for the degrees exactly according to the model furnished. These slight imperfections are, however, in the engraving, of no practical consequence.)

When the prisms are placed so as to stand exactly horizontal the pointer (seen in the cut at the left-hand side of the left disk) points to 0° of each scale of that side.

Rotating the disk by means of the lever so that the pointer moves above 0°, the number of degrees passed over marks the extent of right hyperphoria. In like manner, carrying the pointer below the 0° point marks left hyperphoria.

Bringing the lever, which in the cut is seen to stand vertically, to the horizontal position, the right-hand prism stands with its base down, the left with its base up, and, if the pointer is exactly at 0° of the right-hand scale, the prisms are precisely vertical. Rotation causing the pointer to move up or down marks esophoria or exophoria, respectively.

Thus no change of slide is required, the change from horizontal to vertical prisms being made instantly. The scales mark up to 8°. Beyond this prisms from the trial-case can be used if required.

It sometimes happens that, by virtue of excessive abduction power, the patient overcomes the prisms of the slide, uniting the images. To remedy this, a pair of supplementary prisms are made to slip into the cell behind the permanent glasses. As these supplementary prisms are stationary, the others only rotating, they do not affect the readings of the scales. As a rule, in cases short of actual strabismus, moving the phorometer a foot or more in advance of the eyes serves to prevent the union of images.

The scales represent a far greater degree of accuracy and uniformity than the prisms found in the trial-cases in common use, and the convenience of the two scales is apparent.

The slide is made by Messrs. Meyrowitz Brothers.

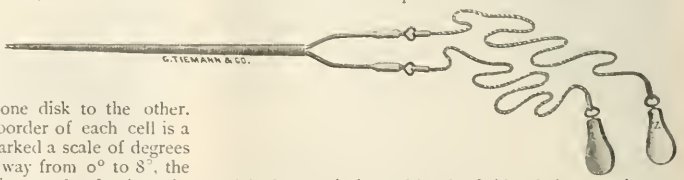
A NEW ELECTRIC PROBE.

By R. L. WATKINS, M.D.,

NEW YORK.

Seeing recently an article in one of the medical papers on electric probes reminded me of the one represented in the cut, which I made several years ago.

It consists of a probe and battery. The former is made of two semi-cylindrical pieces of steel, about one-sixteenth of an inch in diameter and five inches long. These are placed with the flat surfaces toward each other, separated only by the insulation, of which we have a great variety; *e.g.*, rubber, zylonite, silk, paraffine, japan, etc. When the pieces of steel are fastened together, either with silk or insulated rivets, the separation of the ends of the probe should be scarcely perceptible—not more than one one-hundredth of an inch apart.



The battery is formed by the fluids of the mouth coming in contact with a piece of copper and zinc, each of which is connected by means of wires to the ends of the probe.

To operate, zinc and copper are placed in the mouth, one on either side, between the teeth and cheek; the

tongue is now placed against the zinc. When the two ends of the probe touch the metal simultaneously the circuit is completed, a flash of light will be perceived, at the same time the electricity will be tasted on the zinc.

It is not always possible to get the flash, but the taste is invariable, unless the connections are at fault.

The advantages are: 1. No telephone is required. 2. No portable battery is necessary. 3. Simplicity; for the two dissimilar metals can be picked up anywhere, *e.g.*, a ten-cent piece and a penny are generally at hand in one's pocket.

As an illustration, I would cite a patient who recently came to my office with a needle broken off in her hand. I was unable to find it with the ordinary probe, but, applying my electric one, I was soon able to locate and extricate it.

Probes on this principle may be made many ways, as two pieces of copper wire may be insulated from each other and twisted on themselves spirally like a screw, in which case the circuit will be completed by coming in contact with the sides of the probe, as well as in contact with the points.

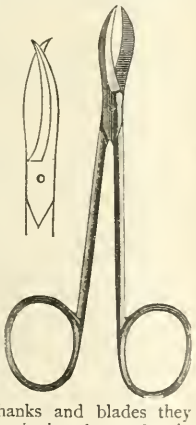
312 West 145th Street.

FRÆNUM SCISSORS.

By G. M. PEASE, M.D.,

San Francisco, Cal.

Having recently to operate for a case of "tongue tie" upon an unusually refractory child, I especially noticed the difficulty of snipping the frænum with ordinary scissors; the tissues would slip away, and instead of one effort several were necessary before the restricting fibres were all cut.



It occurred to me that with scissors made to cut from the points toward the operator, the slipping away would be obviated. Accordingly, a drawing was sent to Messrs. Reynders, who have made some scissors which admirably accomplish the desired result. The points being once engaged in the tissue, there can be no slipping away, and no matter how refractory the patient, one closure of the blades ends the operation.

The size is that of the ordinary iris scissors, but with longer shanks and blades they would serve a good purpose for snipping the uvula; in fact, they might be practically used in a variety of cases.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from January 12 to January 18, 1890.

De Witt, Calvin, Major and Surgeon. By direction of the Secretary of War, the leave of absence granted in S. O. 146, December 21, 1889, Department of Dakota, is extended to include February 20, 1890. Par. 5, S. O. 12, Headquarters of the Army, A. G. O., January 15, 1890.

Black, Charles S., Captain and Assistant Surgeon. The leave of absence for seven days' granted by the commanding officer, Fort Du Chesne, Utah, is hereby extended twenty-three days, with permission to apply to the Adjutant-General of the Army for an extension of three months. Par. 3, S. O. 1, Department of the Platte, January 1, 1890.

Official List of Changes in the Medical Corps of the United States Navy for the week ending January 18, 1890.

Scott, H. B., Passed Assistant Surgeon. Granted extension of sick leave for one year from February 1st.

Woods, George W., Medical Inspector. Detached from Mare Island Navy Yard, and ordered to the Charleston.

Derr, Ezra, Surgeon. Detached from the Nipsic, and ordered home.

Dickinson, Dwight, Surgeon. Detached from Mare Island Hospital, and ordered to the Navy Yard.

Baldwin, L. B., Passed Assistant Surgeon. Ordered to the Michigan.

Cordeiro, F. J. B., Passed Assistant Surgeon. Detached from Mare Island Hospital, and ordered to the Nipsic.

Edgar, J. M., Passed Assistant Surgeon. Detached from the Michigan, and ordered to the Naval Hospital, Mare Island, Cal.

Bailey, T. B., Assistant Surgeon. Detached from the Dale, and ordered to the St. Louis.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending January 18, 1890.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	10	2
Scarlet fever	75	9
Cerebro-spinal meningitis	0	0
Measles	70	2
Diphtheria	94	24
Small-pox	0	0
Varicella	5	0
Cholera	0	0

Easy Deglutition in Cases of Laryngeal Phthisis.—At the last meeting of the British Laryngological and Rhinological Association, Dr. Norris Wolfenden made a very useful suggestion, discovered in the first instance by a patient, whereby the subjects of that painful malady, laryngeal phthisis, may be enabled to swallow without the excruciating pain which usually characterizes the act. The plan consists in placing the patient on his belly on a sofa with the head hanging down. He can then, by means of a tube, or even directly from a cup, imbibe nourishment in liquid form exempt from inconvenience. The success of this plan was testified to by several speakers, and it is worth making known, for it affords a means of removing one, at least, of the horrors of this dire and fatal affection.—*Medical Press and Circular.*

The Wilkesbarre Hospital.—At the annual meeting of the Directors of the Wilkesbarre (Penn.) Hospital, held on January 6th, it was stated that the endowment fund now amounts to $10,744.77. The balance in treasury at the end of the year was $4,344.73, a gain of nearly three thousand dollars over that of the year previous.

Proper Names in Neurological Literature.—Aran-Duchenne's disease: Progressive muscular atrophy. Argyll-Robertson's sign: Absence of pupil reflex. Addison's keloid: Morphœa. Addison's disease: Bronzed skin. Basedow's disease: Exophthalmic goitre. Bell's palsy Paralysis of the seventh pair. Bell's spasm: Convulsive facial tic. Bergeron's disease: Rhythmic localized chorea. Brown-Séquard's syndrome: Hemiparaplegia, with hemianæsthesia of the other side. Cazenave's lupus: Lupus erythematosus. Charcot's disease: Ataxic arthropathy.

Charcot's disease: Lateral amyotropic sclerosis. Cheyne-Stokes' respiration: Uræmic respiration. Dressler's disease: Paroxysmal hæmoglobinuria. Dubini's disease: Electric chorea. Duchenne's disease: Locomotor ataxy. Duchenne's palsy: Pseudo-hypertrophic palsy. Duhring's disease: Dermatitis herpetiformis. Dupuytren's disease: Retraction of the palmar aponeurosis. Erb's palsy: Paralysis of the roots of the branchial plexus. Erb-Charcot's disease: Spasmodic tabes dorsalis. Friedreich's disease: Hereditary locomotor ataxy. Gerlier's disease: Paralysant vertigo. Gibert's pityriasis: Rosy pityriasis. Gibbon's hydrocele: Hydrocele with voluminous hernia. Gilles de la Fourette's disease: Motor inco-ordination with echolalia and coprolalia. Graves' disease; Exophthalmic goitre. Graefe's sign: Dissociation of the movements of the globe of the eye and of the upper eyelid. Hebra's disease: Polymorphous erythema. Hippocrates' facies: Agonized facies of impending fatality. Jacksonian epilepsy: Cortex epilepsy. Kopp's asthma: Thymic asthma; spasm of the glottis. Leber's disease: Hereditary optic atrophy. Menière's disease: Labyrinthine vertigo. Morvan's disease: Analgesic paresis of the extremities. Parrot's disease: Syphilitic pseudo-paralysis. Parrot's sign: Dilatation of the pupils on pinching the skin. Paget's disease: Hypertrophic, deforming osteitis. Parkinson's disease: Paralysis agitans. Parry's disease: Exophthalmic goitre. Pott's aneurism: Anastomotic aneurism. Pott's fracture: Fracture of the fibula by divulsion. Pott's disease: Vertebral osteitis. Raynaud's disease: Symmetrical asphyxia of the extremities. Romberg's sign: Unsteadiness of ataxics in darkness. Romberg's trophoneurosis: Facial hemiatrophy. Rosenbach's sign: Abolition of abdominal reflex. Salaam, tic de: Convulsive salutation. Stokes' law: Paralysis of muscles subjacent to inflamed serous or mucous membranes. Sydenham's chorea: Common chorea. Thomsen's disease: Muscular spasms at beginning of voluntary movements. Trousseau's disease: Vertigo-e-stomacho-leso. Werlhoff's disease: Purpura hæmorrhagica. Westphal's sign: Abolition of patellar reflex.—*Alienist and Neurologist.*

Black-Tongue Fever.—It is reported that an epidemic of so-called black-tongue fever has appeared near Morgantown, W. Va. Four members of one family are said to have died from it, and much alarm prevails in the neighborhood. There was an epidemic of what was called black-tongue fever in some parts of the country in the winter of 1842–43. It is generally supposed to be a malignant form of typhoid fever.

The King of Portugal has a staff of nine physicians to look after his precious health.

A Weekly Rest Congress was recently held in Paris, under the presidency of M. Léon Say, the object of which was to urge the general observation of one day of rest in the seven, which is regarded by the members of the congress as necessary for the preservation of the health of man as well as of beast.

Diphtheria Epidemic in Newfoundland.—Diphtheria has been epidemic in Newfoundland for nearly two years past, it having appeared in St. John's in that form in March, 1888. During that time the disease has invaded over 1,000 families, the whole number of cases being 2,170, and of deaths 427. The Board of Health has done all it could to prevent the spread of the disease, but its work has been hampered greatly by the strange indifference of the people, who seemed either to regard the affection as not contagious or to despair of preventing its spread by means of isolation and disinfection.

Cholera among Medical Men.—During the past year five surgeons have died in India from cholera contracted in the discharge of their duty, viz., Surgeons M. Gaisford, Jolliffe, Kelly, Polden, and Dr. Smith.—*Indian Medical Journal.*

Antiquity of the Guillotine.—It has generally been supposed that the guillotine received its name from Dr. Guillotin, a deputy in the French Constitutional Convention, but this is stated by a physician of Lyons, who has been studying up the cheerful subject, to be erroneous. The real inventor of the instrument is not known, but the one who first recommended its use in France was Dr. Louis, secretary of the Surgical Society, who made a favorable report upon its efficacy on March 20, 1792. Guillotin was the founder of the Academy of Medicine, and an estimable physician, who did not deserve the fate of being known to posterity only as the inventor of an instrument for destroying the lives of his fellow-men. The invention of the instrument should not, however, be credited to any medical man, for it was in use, long before the French Revolution, in Italy and Spain, as well as in England and some parts of Germany.

The Cholera continues to claim many victims in Persia, and the Russian authorities in Central Asia are putting forth every effort to confine the disease within the boundaries of that country.

Laboratories.—New York and Brooklyn have four well-equipped pathological and biological laboratories. The trouble is now to find workers in them. "The harvest is rich, but the laborers are few."

Sundown Doctors is the title given to clerks in the Departments at Washington who have taken medical degrees, and who try to practise after they get home from their clerical work.

A New Operation for Epilepsy, recommended by Dr. William Alexander, of Edinburgh, consists in the removal of the cervical ganglia of the sympathetic. Dr. Alexander has abandoned his operation for ligature of the vertebrals in epilepsy.

The Medical Society of the State of New York.—PROVISIONAL PROGRAMME OF PAPERS FOR THE EIGHTY-FOURTH ANNUAL MEETING, to be held in the City Hall, at Albany, on Tuesday, Wednesday, and Thursday, February 4, 5, and 6, 1890.

TUESDAY, MORNING SESSION (9.30 A.M.). President's Inaugural Address, Appointment of Committees, Executive Business. *Papers:* "The Use of Belladonna in Spasmodic Contractions of the Neck during Labor," by S. S. Cartwright, of Roxbury; "The Time-element in Saving the Perinæum," by Robert L. Dickinson, of Brooklyn; "A Case of Extra-uterine Pregnancy," by H. D. V. Pratt, Jr., of Elmira; "What are the Rational Limitations of Intra-uterine Therapeutics," by Andrew F. Currier, of New York; "Remarks on the Use of the Uterine Curette," by Walter B. Chase, of Brooklyn; "Cancer of the Body of the Uterus," by H. C. Coe, of New York; "The Indications for Operation in Disease of the Uterine Appendages," by Egbert H. Grandin, of New York; "Seven Consecutive Successful Cases of Intubation of the Larynx for Diphtheritic Croup," by Wm. Hailes, Jr., of Albany. AFTERNOON SESSION (2.30 P.M.). "On the Treatment of Eczema in Elderly People," by L. Duncan Bulkley, of New York; "An Original, Simple, and Effective Method for Treatment of Scabies," by Samuel Sherwell, of Brooklyn; "On a Case of Leprosy Apparently Cured," by George Henry Fox, of New York; "Acute Dacryocystitis," by David Webster, of New York; "Spectra of Blood in Certain Eye Diseases," by Lucien Howe, of Buffalo; "Cataract," by Francis Valk, of New York; "A Case of Meningocele Resembling Degeneration of the Lachrymal Sac," by W. F. Mittendorf, of New York; "Purulent Ophthalmia," by J. A. Andrews, of New York. EVENING SESSION (7.30 P.M.). "The Thomas Hip-splint," by J. F. Ridlon, of New York; "A Ready Method for Counter-traction at the Knee," by Henry Ling Taylor, of New York; "The Pendent Limb

in the Treatment of Joint Diseases of the Lower Extremity," by A. B. Judson, of New York; "The Prevention of Tuberculous Bone Lesions," by V. P. Gibney, of New York; "The Question of What Produces and What Prevents Anchylosis of Joints," by A. M. Phelps, of New York; "A Statistical Paper on Club-foot," by W. R. Townsend, of New York.

WEDNESDAY, MORNING SESSION (9.30 A.M.). Executive Business. "Fever and its Treatment," by Alfred L. Loomis, of New York; "A Case of Uræmic Convulsions in New-born—Recovery." by A. Hutchins, of Brooklyn; "Functional Abuminuria, with Three Years' Observation of a Case," by Eli H. Long, of Buffalo; "The Importance of a State or National Registration of Births," by Alexander Hadden, of New York; "Isolation of Consumptives," by P. H. Kretzschmar, of Brooklyn; "The Production of Tubular Breathing in Solidification and Other Conditions of the Lungs," by Charles Cary, of Buffalo; "The Physiological, Pathological, and Psychological Bearings of Sex," by Samuel S. Wallian, of New York; "A Study of Alcoholism in Bellevue Hospital," by C. L. Dana, of New York; "Early Diagnosis of Tubercular Meningitis," by W. P. Northrup, of New York; "Recent Lunacy Legislation affecting the General Practitioner," by E. H. Howard, of Rochester; "The Prompt Recognition and Treatment of Syphilis of the Brain," by J. Leonard Corning, of New York; a paper, subject not yet announced, by Dr. E. F. Brush, of Mount Vernon. AFTERNOON SESSION (2.30 P.M.). "Address on Surgery," by Alfred Mercer, of Syracuse; "The Diagnosis and Treatment of Fractures through the Anatomical Neck of the Humerus," by C. A. Powers, of New York; "Report of Five Cases of Suprapubic Cystotomy for Tumors of the Bladder and Vesical Calculi," by A. Vander Veer, of Albany; "Reflections upon Some Cases of Nephro-lithotomy," by E. L. Keyes, of New York; "A Rarely Described but Common Form of Cystitis in Women," by Robert T. Morris, of New York; "An Extension Splint for the Treatment of Fractures of the Leg, the Arm, and Forearm," by P. R. Furbeck, of Gloversville; "A History of Two Hundred and Fifty Cases of Excision of Superior Maxilla," by J. D. Bryant, of New York; "Treatment of the Diseases of the Rectum Based upon Anatomical Study," by Seneca D. Powell, of New York. EVENING SESSION (8 P.M.). Anniversary Address, by the President. Annual Dinner of the Society (9 P.M.).

THURSDAY, MORNING SESSION (9.30 P.M.). "Methods of Examining the Post nasal Pharynx and Surgical Treatment of Diseases of that Cavity," by C. C. Rice, of New York; "A Case of Papilloma of the Vocal Chords," by Charles N. Cox, of Brooklyn; "The Prevention of Tubercular Laryngitis," by B. F. Westbrook, of Brooklyn; "Nasal Intubation," by D. H. Goodwillie, of New York; "Nasal Epilepsy," by John O. Roe, of Rochester; "Some Practical Suggestions concerning Antrum Disease," by F. H. Bosworth, of New York; "Chronic Nasal Catarrh: Its Causes, Course, and Cure," by O. B. Douglas, of New York; "Naso-pharyngeal Epithelioma," by Sidney Allan Fox, of Brooklyn; "The Etiology and Radical Treatment of Nasal Myxomata," by W. C. Jarvis, of New York.

OFFICERS OF THE SOCIETY.—*President*—Daniel Lewis, New York; *Vice-President*—Alfred Mercer, Syracuse; *Secretary*—F. C. Curtis, Albany; *Treasurer*—C. H. Porter, Albany. *Committee on Business* — George Henry Fox, Henry Flood, Herman Bendell. *Committee of Arrangements*—Samuel B. Ward, Edward L. Partridge, C. S. Merrill. *Committee on By-Laws*—F. A. Castle, A. R. Simmons, F. C. Curtis. *Committee on Hygiene*—E. V. Stoddard, A. N. Bell, W. B. Brown, J. P. Creveling, W. H. Bailey, W. C. Bailey, E. F. Brush. *Committee on Legislation*—D. B. St. John Roosa, B. Pillsbury, M. J. Lewi. *Committee on Ethics*—A. Jacobi, A. Matthewson, H. R. Hopkins. *Committee on Prize Essays*—G. F. Shrady, F. P. Foster, Eugene Beach. *Committee on Publication*—F. C. Curtis, J. O. Roe, O. B. Douglas, C. H. Porter.

The Late Dr. David Clark Cocks.—The New York Ophthalmological Society has been informed of the death of Dr. David Clark Cocks, who has for some years been one of its members and was just elected Vice-President.

Resolved, That we hereby express our sincere and deep regret at his loss, and our tribute of affection and respect for his memory. By faithful and industrious labor he had reached a position of honor among the community and in the profession. He commanded the confidence of all who knew him by the fidelity and uprightness of his character, by the soundness of his judgment, by his skill, and by the conscientious pains which he brought to bear upon all that he undertook.

He was discreet, thorough, observant, and never spared himself if he might serve the distressed. He was imbued with a love of knowledge, and was not only versed in medical literature but was capable of discerning new facts and suggesting new methods in clinical experience.

We have lost a tried and true friend, an excellent coworker, and one for whom the future promised even more than the past had realized.

To his family we offer our sincere sympathy and respectful condolence.—PETER A. CALLAN, RICHARD H. DERBY, J. B. EMERSON, *Committee.*

The Digestibility of Boiled Milk.—It is now very regularly recognized, both by medical men and by the more highly educated section of the community, that it is a wise precaution to boil both water and milk before using them as beverages, and the practice is becoming very common. The growth of pathogenic organisms in these fluids, especially in milk, is often very rapid, and thus diseases may be transmitted from one place to another. The temperature of boiling water puts an end to the life of the microbes, and also to the danger of infection. Another reason why boiled milk is so much used, especially in infant feeding, is that it is supposed to be more easily digestible than fresh milk. If, however, we can draw correct deductions from dogs to babies, it would now appear that this belief in the superior digestibility of boiled milk is founded on error. Dr. Randnitz, of Prague, has recently published, in Hoppe-Seyler's *Zeitschrift für physiologische Chemie*, certain very striking experiments on this subject. He admits, what anyone may confirm for himself, that milk that has been boiled does not, on cooling and the subsequent addition of rennet, form a large coherent clot as does fresh milk; but a flocculent precipitate of casein is produced instead. He shows, however, by analysis of the milk itself, and of the urine and fæces, that much less nitrogenous material is absorbed from milk that has been boiled than from the same milk when fresh. The digestibility of fat is apparently unaltered by boiling; the following figures, however, illustrate the fact just alluded to as to the difference of digestibility of the proteid materials: In three days, 15.6 grammes of nitrogen were given in the form of fresh milk; of this quantity, 13.3 per cent. was found in the fæces; the nitrogen of the urine accounted for 77.3 per cent., so that 9.4 per cent. was retained in store by the growing animal. The animal was next fed on boiled milk; and 10.4 grammes of nitrogen was given in that form in two days; 18.6 per cent. of this was found in the fæces, 75.7 in the urine; so that only 5.7 per cent. was assimilated. The belief in the superior digestibility of boiled milk is, however, so widespread, that we should like to hear of the confirmation of the above remarkable results before we recommend mothers to leave off what is, from other points of view, the very praiseworthy custom of boiling the milk they give to their children.—*The British Medical Journal.*

False Neurasthenia.—Dr. Myrtle writes as follows upon this subject: "We may find symptoms in every respect similar to those of true neurasthenia, and it will take you all your time and patience, as well as tact, to detect the sham from the real. If you hark back a bit, you will find that as a child she showed temper; as she

grew, she became fitful, hysterical, and given to the sulks; craved for sympathy, and exhibited little or no sympathy for others. On questioning her, she describes her sufferings in forcible language. She can neither eat nor sleep; has not an atom of strength; suffers from the most dreadful pain, most fearful headaches, and frightful spasms; and should you suggest any portion of her body, from her head to her heels, as possibly exempt from pain, she often resents the insinuation, and declares that is the very part where she suffers most. While she tells you all this in a sort of whine, her features don't show indications of any agony, and, if you watch her, you will find that she overacts her part Utterly indifferent to the anxiety of parents and friends, or to the trouble and expense she causes, she seemingly finds gratification in watching the unwearied efforts of those around her in doing their best to comfort and help her. While putting on an air of the most abject listlessness while you look at or speak to her, if you talk at her you will learn that she has both eyes and ears; if you assist her in any way she makes herself as helpless as she can—a dead weight. These creatures not only deceive everyone around them, but in time they succeed in deceiving themselves. Were it not so, I cannot understand how they continue p'aying such a sorry game for so long, and with so much strain and fixity of attention, to the exclusion of everything else, as I have seen them do. If we push our inquiries a little further, we generally discover that there is some obliquity of the moral sense; an ungratified whim or disappointed affection at the bottom. —*The Provincial Medical Journal.*

The Hospital Corps in the United States Army.—Congressman Stivers, of New York, has introduced in the House a bill amending the law entitled "An act to organize the hospital corps of the army of the United States, to define its duty, and to fix its pay." The amendment proposed provides that the pay of the privates of the hospital shall be $19 per month, with the increase, on account of length of service, as is now or may hereafter be allowed by law to other enlisted men. It is claimed that the members of the hospital corps are the hardest worked and poorest paid of any men in the army.

Medical Photographers.—The ability to take pictures of one's cases is coming to be a very common accomplishment of the younger generation of physicians. It is said that there are amateur photographers attached to the staff of nearly every London hospital.

International Medical Congress, Berlin, 1890.—I. The Tenth International Medical Congress will be opened in Berlin on Monday, August 4, 1890, and will be closed on Saturday, August 9th. II. The Congress shall consist of legally qualified medical men who have inscribed themselves as members, and have paid for their card of membership. Other men of science who interest themselves in the work of the Congress may be admitted as extraordinary members. Those who take part in the Congress shall pay a subscription of 20 marks (one pound sterling, or $5) on being enrolled as members. For this sum they shall receive a copy of the "Transactions," as soon as they appear. The enrolment shall take place at the beginning of the Congress. Gentlemen may, however, be enrolled as members by sending the amount of the subscription to the Treasurer,[1] with their name, professional status, and residence appended. III. The object of the Congress is an exclusively scientific one. IV. The work of the Congress will be discharged by eighteen different sections. The members shall declare upon enrolment to which section or sections they intend more particularly to attach themselves. V. The Committee of Organization shall, at the opening sitting of the Congress, suggest the election of a Definite Committee (or Bureau), which shall consist of a President, three Vice-Presidents, and of a number—as yet undetermined—of Honorary Presidents and Secretaries. At the first meeting of each section a President and certain number of Honorary Presidents shall be elected; these latter shall conduct the business of the sections in turn with the Presidents. On account of the different languages employed, a suitable number of Secretaries shall be chosen from among the foreign members. The duties of the foreign Secretaries shall be confined to the sittings of the Congress. After the termination of the Congress the editing of the "Transactions," shall be carried out by a committee specially appointed for this purpose. VI. The Congress will assemble daily, either for a general meeting or for the labors of the different sections. The general meetings will be held between eleven and two o'clock. Three such meetings will take place. The time for the sittings of the various sections will be fixed by the special committee of each section, it being understood, however, that no such sittings are to take place during the hours allotted to the general meetings. Joint sittings of two or more sections may be held, provided that the Bureau of the Congress can offer suitable rooms for such sittings. VII. The general meetings shall be devoted to (*a*) transactions connected with the work and general management of the Congress; (*b*) speeches and communications of general interest. VIII. Addresses in the general sittings, as well as in any extraordinary meetings which may be determined upon, can only be given by those who have been specially requested by the Committee of Organization. Proposals relative to the future management of the Congress must be announced to the Committee of Organization before July 1, 1890. The committee shall decide whether these proposals are suitable to be introduced for discussion. IX. In the sittings of the sections, questions and problems will be discussed which have been agreed upon by the special Committees of Organization. The communications of those appointed by the committee to report on a subject shall form the basis of discussion. As far as time allows, other communications or proposals, proceeding from members and sanctioned by the Committee of Organization, may also be introduced for discussion. The bureau of each section decides as to the acceptance of such offered communications, and as to the order in which they shall come before the meeting, always provided that this point has not been already determined in the sitting itself by a decree of the section. Scientific questions shall not be put to the vote. X. Introductory addresses in the sections must, as a rule, not exceed twenty minutes in length. In the discussions no more than ten minutes are allowed to each speaker. XI. All addresses and papers in the general and sectional meetings must be handed over to the Secretaries, in writing, before the end of the sitting. The Editorial Committee shall decide whether—and to what extent—these written contributions shall be included in the printed "Transactions" of the Congress. The members who have taken part in the discussions will be requested to hand over to the Secretaries, before the end of the day, in writing, the substance of their remarks. XII. The official languages of all the sittings shall be German, English, and French. The regulations, the programme, and the agenda for the day will be printed in all three languages. It will, however, be allowable to make use of other languages than the above for brief remarks, always provided that one of the members present is ready to translate the gist of such remarks into one of the official languages. XIII. The Acting President shall conduct the business of each meeting according to the parliamentary rules generally accepted in deliberative assemblies. XIV. Medical students, and other persons, ladies and gentlemen, who are not physicians but who take a special interest in the work of a particular sitting, may be invited by the President or be allowed to attend the sitting by special permission. XV. Communications or inquiries regarding the business of separate sections must be addressed to the managing members thereof. All other communications and inquiries must be directed to the General Secretary, Dr. Lassar, Berlin NW., 19 Karlstrasse.

INTUSSUSCEPTION IN A CHILD OF SIX MONTHS: LAPAROTOMY—EVISCERATION—RECOVERY.

BY FREDERIC KAMMERER, M.D.,

SURGEON TO THE GERMAN HOSPITAL; INSTRUCTOR IN SURGERY AT THE POST-GRADUATE SCHOOL AND HOSPITAL.

THERE can be no doubt that the past years have been very progressive ones in abdominal surgery. The work of Dr. Senn in intestinal anastomosis, for example, has materially widened the field of operative interference in many abdominal cases, and will still continue to do so as our experience with the method increases. But surgeons will occasionally still feel the want of precision in our diagnostic, as well as therapeutic, resources in that vast class of cases which are of the greatest interest to the surgeon proper, *i.e.*, intestinal obstruction. I refer mainly to the localization of the seat of obstruction and the advisability of a large abdominal incision with eventration, or of a small one without it. Theoretical reasoning will advance our knowledge to no great extent in this direction, but well-observed cases, compiled in large statistics, are the only means, assisted by the results of experiments, of determining such therapeutic problems, which, until then, must be left to the personal feeling and experience of the surgeon. The following case has perhaps some bearing on these points:

J. Q——, a child of exactly six months, was taken ill on Saturday night with pain in the abdomen. Toward Sunday morning tenesmus set in, accompanied during the day by evacuation of blood per anum. Vomiting began on Sunday morning. No fecal matter had escaped since Saturday night. Dr. H. Kudlich, of this city, saw the patient on Sunday evening, and diagnosed an intussusception. The symptoms continued with more or less severity until I saw the patient on Tuesday at noon. At that time, about sixty hours after the child had first been taken ill, there was present a slight degree of collapse. Vomiting had occurred only once on that day, tenesmus was less marked, and the bloody discharges had ceased. No gases or fæces had passed. There was little tympanites. The child was restless and seemed somewhat in pain; the abdomen was soft and compressible, and on palpation nothing abnormal could be detected. Digital examination per rectum seemed, at first, to confirm the results of external palpation. However, on introducing the finger high up into the rectum and practising bimanual palpation, it seemed to me as if there existed a thickening of some part of the intestine to the right of the median line, near the rim of the pelvis, but this, I must concede, was very indistinct. The child was put under chloroform, and an attempt was made to overcome the obstruction by water enemata under high pressure in the inverted position. Although large quantities were used, no influence was evidently exerted upon the intussusception, as the violent tenesmus and the expulsion of the injected fluid with only mucus and traces of blood proved when the patient began to recover from the narcosis. Laparotomy was now suggested as the only measure available, and the child transferred to the German Hospital. There, Dr. Caillé, who happened to be present, saw the little patient with me. That gentleman also felt, per rectum, that seeming thickening of the walls of the gut, but was more positive in locating there the seat of trouble than I had been. He also kindly called my attention to an area of tympanitic percussion-sound of about the size of a silver half-dollar, about two inches above the inner half of Poupart's ligament. The child was now once more narcotized, with a view to a final attempt of restoring the continuity of the intestinal canal with enemata, and in this state I made another rectal examination. Now I immediately and distinctly felt a tumor, movable to a certain extent, the size of a hen's egg, soft to the touch, which, there was no doubt, was continuous with the intestine. It lay in the cæcal region. The advantages of an examination in narcosis in all cases of abdominal disease, pending surgical interference, was again brought home to me, and I was reminded of the service often rendered by such an examination in cases where we believe our diagnostic resources have been exhausted without an anæsthetic. I am not referring here merely to those cases in which a diagnosis is impossible unless the patient be narcotized, but to such where we have examined the patient under the most favorable conditions (lax abdominal walls, moderate development of adipose tissue, etc.), without the anæsthetic, and are then surprised at being compelled to modify our diagnosis considerably after applying the same. No result having again been obtained by water injections, laparotomy was immediately performed, ether being substituted for chloroform. I first made an incision through the linea alba from a little below the umbilicus to the symphysis.

After opening the abdominal cavity I introduced two fingers, in the hope of immediately finding what I had so distinctly felt by bimanual palpation. In this I was disappointed. After a few moments' useless search, fearing that too much manipulation of the intestines would increase the danger of shock without the guarantee of success, I quickly prolonged the incision beyond the umbilicus and permitted the small intestine, which was moderately distended, to push out through the abdominal wound. It was caught in hot aseptic towels, kept warm by irrigation. Only after the entire small intestine had been eventrated did the intussusception come into view. It proved to be of the ileo-cæcal variety. Disinvagination of the intussusception caused considerable difficulty, and, considering the length of time that invagination had existed, I had some doubts of being able to accomplish it at all. No adhesions had formed. With traction on the intussusceptum, supplemented by pressure on the intussuscipiens, continued for several minutes, the constriction at the neck yielded, and immediately the invaginated gut unfolded itself, the cæcum and vermiform process appearing last. The gut implicated was about six inches long. It was of healthy appearance everywhere, with the exception of a deep black furrow on one side of the intussusceptum, where the neck had exercised pressure. Nor did this part of the gut regain its normal color after it had been liberated, but the gloss peculiar to the peritoneum was still present.

I therefore concluded to replace it in the abdominal cavity, and I was more ready to run this risk in so young a child, in whom the prognosis of some other prolonged intestinal operation would certainly have been a very unfavorable one. Although the intestines were only moderately distended, it was with much difficulty that their reposition was effected. The abdominal incision was rapidly closed with a single row of sutures, taking in all the layers. The little patient rallied well from the operation and his

recovery was uninterrupted. During the first week, and even longer, the bowels were at times very frequently moved, on which account the child was kept under the influence of opium until the sutures were cut away on the tenth day. The operation was performed two months ago, and the patient is now in perfect health.

Another case, also of a child of six months, of successful laparotomy for intestinal obstruction was reported by the late Dr. Sands,[1] twelve years ago. The case was in many particulars identical with the one under consideration. It was also an ileo-cæcal invagination, in which, however, laparotomy was resorted to sixteen hours after the symptoms had first set in. The case differed in this much from my own, that the intussusceptum could be felt per rectum and that disinvagination resulted from the use of enemata and kneading of the abdomen until all but about one and one-half inch of the invagination had been reduced, leaving, indeed, at the time of operation, precisely the same pathological condition as in my own case.

To judge from the difficulty I experienced in unfolding the ileo-cæcum, I am convinced that no amount of pressure from the rectum, by enema or insufflation, could have safely overcome the intussusception. It is true Senn[2] tells us of an experimental ileo-colic invagination which was reduced on the third day by rectal insufflation of hydrogen gas, laparotomy having been previously performed. In this experiment, however, the objection that removal of all intra-abdominal pressure by incision may have assisted the intentions of the operator cannot be entirely disregarded, even if in other cases an anæsthetic be given to the extent of complete relaxation of the abdominal walls. But are the conditions of such an experiment perfectly identical with the pathological changes in a case of pronounced intussusception? In the experiment disinvagination was prevented by sutures at the neck of the intussuscipiens, which were removed on the third day before insufflation was practised. Plastic exudation covered the neck at the time, and was, I am led to believe, the only obstacle to disinvagination. In many cases of pathological intussusception, however, strangulation has occurred at the seat of disease, to what extent I have not been able to form an opinion. Such strangulation we know is due to swelling of the intussusceptum or to malpositions of the invaginated gut (twisting and curving). Where it does exist, I feel satisfied not much is accomplished by enemata or insufflation, but everything by careful and early manipulation of the inturned gut after laparotomy. The intussusception is truly in the position of a strangulated hernia, as Treves[3] remarks. In justice to Senn it must, however, be said that he is a warm advocate of laparotomy, when a faithful attempt at reduction by insufflation has failed.

I think I feel justified in drawing conclusions as to the advisability of a small or a large abdominal incision from my case. That I did not succeed in finding the intussusception does not militate against a small incision. In intestinal obstruction I believe that the general rule ought to be to make an incision only large enough to permit the introduction of the entire hand into the abdominal cavity, whether this be followed by an intra-abdominal search for the obstruction, or the drawing forth of a loop of intestine only at a time. But it must be remembered that, in a child of six months, the introduction of the entire hand is the equivalent of an incision large enough to permit easy evisceration, or, perhaps more correctly, to defy its prevention during the necessary manipulations. I think that a search with two fingers is entirely insufficient, when we should run no risk of prolonging the operation unnecessarily.

I have mentioned a small area of exquisitely tympanitic sound in the right half of the hypogastric region, which was distinctly defined from the metallic percussion-sound of the rest of the abdomen. The explanation of this phenomenon would seem to be that here there were two different parts of the intestinal tract under different degrees of tension. I fear that in very few cases of intestinal obstruction will this symptom be available, and when it does exist, in connection with other symptoms, it ought only to be considered as indicative of an obstruction in general, but not as pointing to the seat of the lesion. In most cases of obscure intestinal obstruction we generally find meteorism present to a greater or less extent. Where this is in any way pronounced, the distended viscera will gravitate upward, giving the entire abdomen a metallic percussion-sound. This is not merely verified by post-mortem experience, but also by cases of surgical interference. In acute intussusception, where there is little of any tympanites, it may happen, as in my case, that a loop of the gut lying below the constriction may still rest against the anterior abdominal wall. In such, as it appears to me, rare cases, the diagnostic value of the symptom is evident.

That the age of the patient can no longer be considered as a counter-indication to laparotomy is, I presume, generally accepted, and is proved by such cases as Dr. Sands' and my own. And when we bear in mind the miserable prognosis of spontaneous elimination of the intussusceptum in children, and the almost absolutely fatal prognosis of resection of the invaginated gut or of an artificial anus,[1] the tendency to early operative interference, as lately manifested, is readily understood. The points brought out by this case seem to be:

In cases of acute intestinal obstruction in very young children (mostly intussusception), where reduction by enemata or insufflation has failed, laparotomy ought to be immediately resorted to.

It is to be remembered, in this connection, that at the end of the third day the intussusception may still be reducible after laparotomy, and that prolonged attempts ought always to be made before reduction is considered impossible.

In very young children, taking into consideration the smallness of the field of operation, the absence of meteorism, facilitating the replacement of the intestines, the probability of being able to find the obstruction in less time, and the fact that two cases have been successful in children only six months old, it seems the better plan to make a large incision accompanied by evisceration.

After the obstruction has been found the intestines should be immediately returned to the abdominal cavity before further manipulations are undertaken. This will be the surest way of preventing shock or intestinal paralysis.

SUPPURATIVE FEVER: IS THERE SUCH A DISTINCT AFFECTION, AND ARE THE "TRAUMATIC INFECTIOUS DISEASES" MANIFESTATIONS OF IT?

By HENRY S. STARK, A.B., M.D.,

NEW YORK.

In order to establish the identity of a particular disease it is necessary, first, to show that the disease under consideration is produced by a special cause manifesting itself by distinct pathological conditions; and, secondly, it must be shown that the disease possesses distinctive features pertaining to its symptomatology and clinical picture not common to other affections. Whenever the exigency arises, and the above conditions have been fulfilled, we can rejoice that our nosology has been enriched by a new disease.

Although the disease with the above title has never been credited with any particular place in the classification of fevers in any work on general medicine, and has only been considered in outline in works on surgery, never-

theless there exists sufficient clinical evidence, based on recent bacteriological discoveries, to warrant the belief that such a disease is of frequent occurrence, and that it invariably manifests itself by pathological changes in the blood and the tissues that occasion a constant train of well-defined symptoms which render the diagnosis unmistakable.

The only explanation for this discrepancy that occurs to my mind is the fact that the specific character of the fever has only become definitely established within the last decade, and mainly through the efforts of Koch, Rosenbach, Ogston, *et altera*.

Throughout this paper the term "suppurative fever" will be employed to denote an acute, infectious, constitutional disease, characterized by a febrile movement and the production of pus containing special pathogenic bacteria and micrococci, and caused by infection from a wound, whether surgical or traumatic, or from a solution of continuity upon an exposed surface, as the skin, or upon a mucous or serous membrane. The febrile reaction may be continuous, intermittent, or paroxysmal; the location of the inflammatory products may be confined to one spot, or may embrace different and distant parts of the body; while the morbid processes themselves may be, on the one hand, so slight in character that the local phenomena of the affection may escape detection, or, on the other hand, these processes may be so destructive as to cause complete disorganization of tissues.

It will thus appear from what has preceded that this paper is intended as an argument in favor of the theory that the diseases generally classified as the "traumatic infections," viz., septicæmia, pyæmia, septo-pyæmia of Hueter, progressive suppuration, erysipelas, and puerperal fever, are all types, of varying intensity, virulence, and locality, of one and the same disease, that might properly be styled "suppurative fever," since this term furnishes a clearer conception of the pathology and the symptomatology of these diseases than the term "traumatic infections," which was coined some years ago when the mode of onset of these diseases was better understood than their etiology and pathology.

As regards the nature of septicæmia and pyæmia, and the many vague points of distinction which have been drawn between them, the consensus of opinion in view of our advanced knowledge of bacteric medicine is already in favor of the theory that these diseases cannot be differentiated clinically, pathologically nor experimentally, since both stand in a causative relation to pathogenic bacteria that are similar in size, shape, behavior, arrangement, and color.[1]

The microbic origin of septicæmia and pyæmia is now generally accepted by the profession, the main etiological difference between them being that septicæmia owes its origin to rod bacteria, and pyæmia to globular bacteria; and secondly, that the *materies morbi* of septicæmia is absorbed by the lymphatics, while in pyæmia the poison enters the general circulation through the veins.[2]

There is, however, one species of systemic intoxication that cannot be directly attributed to bacterial infection and is not necessarily attended by the process of suppuration, namely, that variety that is due to the presence in the blood of certain alkaloidal chemicals, derived from the decomposition of albuminous and nitrogenous matter and termed by Selmi and Gautier respectively ptomaines and leucomaines. To this category belong those intestinal septicæmias so frequent among children during the summer months, also the symptomatic complex of Bouchard,[3] named by him stercoræmia. The former classical ground of separation between septicæmia and pyæmia, namely, the occurrence of metastatic deposits in the latter and their absence in the former, no longer obtains, especially since microscopic metastatic deposits, and even venous thrombi, have been demonstrated in septicæmia.

[1] Koch: Untersuchungen über die Aetiologie der Wundinfectionskrankheiten der Thier. Leipzig, 1878.
[2] Wagner's Manual of Pathology, p. 593.
[3] Dujardin-Beaumetz: On New Medications.

Birch-Hirschfeld[1] thus discriminates between the two. By the term septicæmia he understands an alteration in the blood caused by absorption of the products of putrefaction, and defines pyæmia as a general infection which proceeds from the surface of wounds or from a focus of suppuration probably evoked by specific organisms. This distinction is undoubtedly fallacious, when it is remembered that the process of putrefaction is itself due to the fermentative action of micro-organisms, the bacillus saprogenes (Rosenbach), which is intimately connected with the bacterium termo (Dujardin), and consequently his definition involves a repetition of the same meaning in different words.

Neither Hueter, Burdon Sanderson, nor Billroth, in defining these terms, make any reference to the bacterial origin of these processes; on the contrary, the last mentioned states that the pus of pyæmic patients does not always contain cocci, nor has "he seen bacteria in the blood of pyæmic patients."[2] Thus Billroth's views are entirely at variance with the accepted facts derived from Ogston's experiments, that pyæmia does not depend upon the entrance of pus pure and simple into the general circulation, but upon pus charged with specific cocci or bacteria.

As an example of the wonderful progress of the medical sciences within the last ten years, contrast the radical views of writers of our own day; Ogston, for instance, who believes that these two processes are not diseases as such, but are simply secondary phenomena of microbial poisoning, while Delafield, in his article on "Pyæmia" in "Ashhurst's System of Surgery," uses this term as a general one to designate the entire group of traumatic infectious diseases.

The views maintained by observers prior to 1884, at which time Rosenbach published his remarkable discoveries of the pus-generating cocci, must be considered ancient and untenable. For in his monograph[3] Rosenbach furnishes experimental evidence so strong as to leave it scarcely a matter for doubt that the surgical infectious diseases are allied processes, and inseparably connected with his pus organisms, or the staphylococci or bacilli of Passet.[4] These experiments furnished the profession at large with an illustrious example of history repeating itself; for just as prior to 1884 septicæmia and pyæmia were considered as distinct affections, so before Koch's discovery in 1882 of the bacillus of tuberculosis, pulmonary phthisis and tuberculosis were regarded by Virchow, Niemeyer, etc., as distinct diseases.

Apart from the similarity of pyæmia and septicæmia as regards their bacterial origin, there is extant a mass of clinical facts that completely harmonizes with the deductions of experimenters. Thus it is known that necrosed uterine stumps, or ovarian pedicles that have been strangulated by ligature, may be dropped into the peritoneal cavity with perfect immunity from sepsis, providing no pathogenic microbic infection has taken place, extraperitoneally; likewise it is known that pus may escape into the peritoneal cavity from the rupture of a pyosalpinx without proving fatal, providing the tube be promptly extirpated and the wound properly treated.

If, now, we argue analogously with regard to the other traumatic infectious diseases, we can establish, *prima facie*, a close connection between puerperal fever and erysipelas, a connection which, to say the least, likewise arouses the suspicion that these infectious diseases are also linked together by a common microbial element. I am not now advocating the clinical relationship between puerperal fever and erysipelas, for that was already recognized in the eighteenth century, and since this date facts derived from reports of epidemics of these diseases have been

[1] Birch-Hirschfeld: Untersuchungen über Pyæmie, Archiv für Heilkunde, 1873, Band XV., p. 193.

[3] Rosenbach: Die Micro-organismen der Wundinfectionskrankheiten des Menschen. Wiesbaden, 1884.
[4] Passet: Untersuchung über die Aetiologie der eiterigen Phlegmone des Menschen. Berlin, 1885

steadily accumulating which illustrate the reciprocal influence that each possesses to generate the other. The whole tendency of very recent investigation is daily rendering it more and more certain that puerperal fever is not an "essential" fever in the commonly accepted sense of this word, but that it is a pyæmia, or a septicæmia manifesting itself by constitutional disturbances, and contracted during the puerperium from microbial infection through a solution of continuity in the parturient canal. The first to clearly demonstrate the auto- and heteroinfectiousness of the disease was Semmelweis, in 1847. In 1865 Mahrhofer [1] called attention to certain vibrios found in the uterine cavity of patients suffering from puerperal fever. Since that time Pasteur and Doléris [2] claimed to have found the specific pathogenic microorganism. The latter submitted to the culture-process of Pasteur fluid obtained from vesicles which developed in the course of erysipelas, with the result that micrococci in chains, also bacilli, were found in the liquids employed identical with those he had discovered in puerperal fever. Pasteur's organism of puerperal fever, when injected beneath the skin of animals, gives rise either to pyæmia or septicæmia, depending upon the method of cultivation; in this manner he has demonstrated the identity of the two forms of puerperal infection.

In 1883 Fehleisen [3] announced his discovery of the streptococcus erysipelatis. It was afterward found, by himself and others, that the microscopic appearance of the individual coccus, as well as cultivations of them, very strongly resemble Rosenbach's streptococcus pyogenes; further, it was also found that both of the last-named cocci possessed the peculiarity of rapidly extending along the course of lymph-vessels. Besides these points of resemblance between these different cocci, it was further demonstrated that the erysipelas cocci bore a close resemblance to the streptococcus found in the tissues of the victims of puerperal disease. Thus the cocci of these diseases are so identical that single ones can scarcely be differentiated microscopically nor morphologically. The most conclusive evidence of the intimate connection between puerperal fever and erysipelas, from a bacteriological stand-point, was furnished by the experiments of M. Vidal within the last four years. A precise estimate of the conclusiveness of these experiments is furnished by the results obtained. M. Vidal, in a long chain of carefully conducted experiments on animals, established the fact that the cocci of puerperal fever give rise to erysipelas, and then produce the same clinical picture as the streptococcus of erysipelas.

The fact that the microbes usually associated with the traumatic infectious diseases differ in species and genera—that is, bacteria are found in one disease, micrococci in another, and bacilli in still another—does not furnish an argument against the identity of these diseases; for we must not attribute too much importance to such a classification of bacteria as Cohn's, the one so generally adopted by bacteriologists, since it is at best an arbitrary one adopted for convenience, and is based upon the form and size of these organisms rather than upon their functions and properties; in point of fact, it has lately been demonstrated that the same organism may cause diseases which differ very materially from each other as regards their symptomatology, according to the method of inoculation and the media in which they are cultivated. The fact that the life-history of these lowest forms of vegetable organisms, especially their mode of reproduction, is still shrouded in an atmosphere of obscurity has led very competent observers to believe that they cannot, therefore, be divided by any hard and fast lines into species and genera. On the contrary, recent researches have demonstrated that several of these organisms successively assume the different shapes embraced in Cohn's classification.[1]

To sum up briefly, as far as we have gone, the following points of analogy between the traumatic infectious diseases may be assumed:

1. They are nearly always attended by a febrile movement and other manifestations of an inflammatory disease.
2. All are attended by similar constitutional disturbances.
3. All are dependent upon infection from microbes that are identical in appearance and behavior.
4. They are all generated in putrefying media.
5. All are accompanied to a greater or less extent by the process of suppuration.

These points of analogy, I believe, are sufficiently conclusive to warrant the assumption that there is a traumatic disease, *per se*, whose distinguishing characteristics are fever, infection, and suppuration; whether we call this disease "suppurative," or "traumatic," or "putrid," or "pyogenetic" fever, or what not, is practically immaterial, the point is, to recognize it as a distinct pathological entity.

In this connection acute suppuration must be separated from chronic suppuration. The latter variety does not enter into consideration in our discussion, since the suppuration of chronic abscesses is admitted to be etiologically identical with tuberculosis from the fact that tubercle bacilli have frequently been demonstrated in the pus of such abscesses and because patients suffering from chronic suppurative processes have finally, in a generality of cases, succumbed to general or to pulmonary tuberculosis. Further, Koch, Rosenbach, and others, injected pus from chronic bone abscesses into the knees, pleura, and peritoneum of animals; the greater number of these became affected with typical local tuberculosis. There are, however, those who believe that even the pus of chronic abscesses at some time or other did contain microbes, but that they have ultimately disappeared through the molecular disintegration of the pus cells and the chemical decomposition of the other pus-elements.

The view that the relationship of acute suppuration to microbial infection is one of cause and effect never took definite shape until Ogston,[1] Rosenbach, and, very recently, Steinhaus [2] made public their observations based on personal experiments. All of the experiments of these men were conducted with the aid of the latest devices known to microscopists and in strict conformity with the Listerian principle, consequently they are of inestimable value as experimental evidence.

Ogston was the first to demonstrate the constant presence of micrococci in acute abscesses. He examined the pus of 88 abscesses of all descriptions with the following result—70 acute and 4 chronic abscesses contained characteristic micrococci. The remaining 14 cases were all chronic bone or glandular abscesses in which the pus had undergone changes and did not contain organisms. Ogston drew the following conclusions from his observations: 1, Micrococci are the most frequent cause of acute suppuration; 2, in all clinical cases of acute suppuration micro-organisms can be demonstrated; 3, micrococci can cause septicæmia.

Rosenbach made microscopical examinations of, and cultivations from, the pus of 26 unopened acute abscesses and discovered the pus organisms in 24 of his cases. The two non-microbic cases were suppurating ecchinococcus cysts, and of these Rosenbach delivers himself as follows: "I hesitate to ascribe the inflammation to the parasites as such, for on the one hand ecchinococci can exist in the body a long time without causing suppuration, and on the other hand because microbes were not found it does not follow that they were not present and did not die out later." Rosenbach's conclusion is that acute suppuration is the consequence of infection. Steinhaus' experiments extended over a series of 49 cases, 4 of chronic abscesses

and 45 of acute abscesses. Of the former, microbes were found in only one case and this was the tubercle bacilli, while in the 45 cases of acute abscesses pus organisms were demonstrated in all. Besides the experiments just cited a number of others made by careful observers is on record. These have been collected and tabulated by Steinhaus in his monograph on the "Etiology of Suppuration." The subjoined schedule is reproduced from this work:

Pus-organism.	Ogston.	Rosenbach.	Passet.	Garré.	Hoffa.	Tilanus.	Kranzfeld.	Zuckerman.	Jakowski.	Steinhaus.	Total.	Per cent.
Staphylococci	31	16	20	68	87	15	26	28	10	29	330	66.5
Streptococci	17	15	8	3	12	4	20	6	11	5	101	20.4
Micrococcus pyogenes tenuis	..	3	..	..	..	1	..	..	..	1	5	1.0
Bacillus pyogenes fœtidus	..	..	1	..	..	1	..	..	2	..	4	0.8
Micrococci similar to pneumococci	..	.	2	..	..	..	..	..	..	.	2	0.4
Staphylococci et streptococci	16	5	2	1	1	..	7	..	7	8	47	9.5
Staphylococci et micrococci pyogenes tenuis	..	.	..	..	..	..	..	..	1	1	2	0.2
Streptococci et micrococci pyogenes tenuis	..	.	..	..	.	..	..	..	1	1	2	0.4
Staphylococci et bacillus pyogenes fœtidus	..	..	..	..	..	..	..	..	1	..	1	0.2
Streptococci et bacillus pyogenes fœtidus	..	..	..	..	..	..	..	..	3	..	3	0.6
Total sum	64	39	33	72	100	21	53	34	35	45	496	100.0

Summary of above.—Staphylococci alone, 66.5 per cent.; streptococci alone, 20.4 per cent.; mixed infection, 9.5 per cent.; remaining infection, 3.6 per cent.

The question whether suppuration can arise independent of microbial infection is still *sub judice*. Efforts, however, to prove that non-microbic suppuration is a possibility have recently met with fruitful results. In this way certain sterilized irritative chemical agents, as oil of turpentine, oil of cantharides, tartar emetic, concentrated solutions of corrosive sublimate, etc., have been shown to possess pyogenic properties when injected under the skin of animals. But granted that chemical or mechanical irritation can provoke suppuration, it does not contradict my claim, for in the beginning of this paper I stated explicitly that I am confining my proposition to the traumatic infectious diseases. The suppuration that accompanies these diseases all admit to be microbic.

If, now, we extend our field of inquiry by examining into the etiology of fever and the relation of fever to the process of suppuration, we find substantial evidence that a coincidence between microbial infection, fever, and suppuration is consistent with our present state of knowledge; in fact, the medical literature that bears upon these subjects has been of late strongly corroborative of the view[1] that the fever of the infectious diseases is either directly due to the action of micro-organisms or indirectly to their chemical products, the ptomaines. Our knowledge of the etiology of special fevers confirms the view that, under certain favorable conditions, bacteria become endowed, when circulating in the human economy, with marked pyogenic properties. The *modus operandi* of this special endowment is still a matter of speculation. We do not as yet know whether these organisms exercise this evil prerogative by virtue of unknown physical or chemical reactions, or by some unknown power. The fact remains that they may become a fruitful source of inflammatory processes. Kocher[2] goes one step further and asserts that acute suppuration is nothing but an "intense inflammation."

The accumulation of such evidence seems to supply the one link lacking in the chain of proof to establish the essentiality of "suppurative fever." The natural sequence of events in this affection would be about as follows: 1, Trauma, artificial or accidental; 2, infection; 3, suppuration; 4, fever. In the ground already traversed by this article, I have maintained that the traumatic infectious diseases are not maladies *sui generis*, but secondary phenomena of microbic poisoning. I have corroborated my views by pathological inferences that are accepted as axiomatic truths by those whose knowledge entitles them to consideration because they have kept pace with the advances of our own times. I have further endeavored to establish the fact that the terms "septicæmia," "pyæmia," "septo-pyæmia," no longer retain their original signification; on the contrary, they are obsolete. The exposition of these facts forcibly reminds us that the entire subject of the pathology and etiology of the infectious diseases ought to be rewritten from the stand-point of the germ-theory of infection.

All of the arguments so far adduced in support of my theory have been derived from the study of micro-organisms, but this fact should not lead to the belief that suppurative fever is entitled to recognition as a distinct affection on such evidence alone. The probability is further strengthened by the fact that clinical experience corroborates the results of bacteriological researches. One of the principal events which make up the clinical history of "suppurative fever," and one that may be viewed as pathognomonic of the disease, is that train of symptoms that is spoken of as hectic fever. This type of continuous fever, although generally associated with pulmonary tuberculosis, is just as frequently present in other lesions of a suppurative tendency. The fact is well established that a hectic movement invariably arouses the suspicion that suppuration is going on, while the intensity of the fever serves as a guide to the activity of the suppuration. Given a case of pelvic inflammation, if the accompanying fever is of a hectic character we can surmise the presence of pus long before fluctuations and tenderness can be elicited. So in pulmonary tuberculosis the hectic cycle warns us that there is a suppurative breaking down of lung parenchyma. In many of these cases the thermometer, by detecting a hectic movement, will enable one to form a correct judgment of the condition of the lung perhaps long before the physical signs and symptoms reveal the presence of consolidation. So in a surgical case, as an amputation of a limb or an exsection of a joint, if some days after the operation the thermometer indicates a hectic movement, the operator concludes that suppuration has taken place, and that his elaborate dressing must be removed. The recital of these cases, and the innumerable parallel ones that these serve to recall, strongly suggests the possibility that hectic fever is a species of suppurative fever, or if not, it is an almost invariable concomitant of this disease.

Hectic fever is nature's method of announcing pus, for just as in physics "nature abhors a vacuum," so in medicine it may be said that nature abhors pus in the living body.

Transplanting Tuberculosis.—The State Board of Health of California has been greatly exercised over the danger to which it believed the State is exposed through the immigration of a large number of persons suffering from tuberculosis. It even suggested, in a recent bulletin, the advisability of establishing a strict quarantine against consumptives until measures of isolation and disinfection could be undertaken. The daily press of San Francisco has not been slow to take up the question, and the result has been a scare and a sensation of such magnitude that even the proposed prize-fight has been for the moment forgotten.

REPORT OF A CASE OF TYPHOID FEVER WITH AN UNUSUAL COMPLICATION.

By WILLIAM W. GRAVES, M.D.,

ST. LOUIS, MO.

I HAVE recently met with a case of typhoid fever in which, as far as I can ascertain, a rare complication existed. I therefore desire to place the case on record. It terminated fatally.

CASE.—Annie E——, aged ten, who had been previously strong and healthy, was first seen by me on the evening of October 20, 1889, while visiting her mother, a convalescent from a six weeks' attack of typhoid fever. On examination I found marked tenderness and gurgling in the right iliac region, enlargement and tenderness in the region of the spleen, and some tympanites. Temperature, 102.5° F.; pulse, 100. I learned from the mother that for the past three or four days the child had little or no appetite, had been drowsy, and would feel tired upon the slightest exertion. She had headache, backache, was constipated, and had epistaxis several times. With this history and array of symptoms, together with the fact that this little girl had constantly attended to the wants of the mother, emptied the discharges, etc., I felt thus early constrained to make a diagnosis of typhoid fever.

I visited the patient twice daily, and found the characteristic morning fall and evening rise of temperature. On October 23d, three days after the first observation and about the sixth day of the disease, the temperature was 100.5° F.; pulse, 112. On this occasion, while examining the patient, I noticed several dusky red, irregularly shaped patches, varying in size from a split-pea to the thumb-nail, situated in the right iliac region. They were slightly elevated, disappeared on pressure, and would quickly return when the pressure was removed. The adjacent skin was normal. There were also points of normal looking skin within the patches, where I also observed from two to eight vesicles, not larger than a pin's head.

On October 24th, evening, temperature and pulse were the same as on the previous day. The patches in the region of the pubes had become confluent, and others had appeared on the upper portion of the abdomen, on the vulva, and on the flexor surfaces of the thighs, not lower than the middle third.

October 25th, evening.—The abdomen is now completely covered by the eruption. No points of healthy skin are to be seen. It is diffuse and of a dusky red color. Many of the vesicles upon the abdomen have become pustular. The eruption has extended upward to the chest, several patches being also seen upon the flexor surfaces of the arms and wrists; and downward to the thighs and legs, being most marked upon the flexor surfaces.

October 28th, evening.—Temperature, 105° F.; pulse, 124. The temperature has been the same for the past three days; the morning temperature has been from 0.5° to 1° less than the evening. This is now the eleventh day of the attack, and the fifth day since the patches first appeared. It now appears to have reached its maximum intensity. The rash is now seen over the entire body with the exception of the face and scalp. On the neck it is very scant, on the flexor surfaces it is abundant, while on the extensor surfaces it is scanty. It is confluent only on the flexures of joints, and on the abdomen. There are some pustules in every portion of the body, but mostly on the abdomen. The skin in this region feels thick, dry, and leathery in a marked degree. In other parts it is similar, but not so well marked. During the development of this rash the patient at no time complained of burning or itching of the skin. There has been no delirium, and, notwithstanding the continued high temperature, the condition of the patient is excellent. She has taken nourishment regularly, and has slept well. Throughout the attack constipation has been the rule.

October 29th, evening.—Temperature, 104° F.; pulse, 120. Desquamation has commenced on the abdomen. From this day desquamation progressed rapidly, proceeding in the order of the development of the rash. In five days the exfoliation was complete, the epidermis peeling off from the abdomen, back, and extremities in laminæ varying in size from a ten cent piece to that of a silver quarter dollar, while that from the palmar and plantar surfaces was detached in perfect casts. As exfoliation progressed there was a corresponding decline in the temperature and pulse-rate, so that by the fourteenth day of the disease the former was only 100° and the latter was 96. The emaciation was not great, and the patient was able to sit up in the bed without assistance. The tongue became clean and moist, and the patient expressed a desire for solid food, which, however, was not permitted. By the evening of the sixteenth day of the attack, to my great surprise, the temperature was 102.5° F.; pulse, 110. The tongue again became coated. Tenderness in the right iliac region, which had subsided, was again marked.

On the second day of the relapse the temperature was 104° F.; the pulse 130; the patches again appeared on the abdomen.

Third evening of the relapse.—Temperature, 105° F.; pulse, 140. The mother states that the patient had a rigor which lasted thirty minutes, and since that time has been very restless. Patient complains of pain in the chest, not localized, but general. She has a short, dry cough, which is somewhat painful. There is no dulness on percussion, but at several points at the base of each lung percussion elicits some tenderness. Over the upper portions of both lungs there were high, shrill, whistling rhonchi to be heard, and over the lower portions abundant small moist râles. The respirations are greatly increased, being 55 to 65 per minute, whereas at no time before had they ever been more than 35 per minute. The diagnosis of capillary bronchitis, as an additional complication, is made. The rash is spreading, as it did in the primary attack, to the chest and thighs.

Fourth evening of relapse.—The patient has been delirious most of the day, the delirium being of a muttering form. There is sordes on the teeth and lips. The tongue is dry and parched. The respirations are labored and costal in type, being 70 to 75 per minute. Expiration is prolonged and sighing. Temperature, 105.5° F.; pulse, 150. She has had ten stools during the day. The rash again seems to be fully developed. As before, it is confined principally to the flexor surfaces. It is not as intense as before, the color is more faint, and the skin is not so thick and dry. There are also fewer vesicles and pustules.

Fifth evening of the relapse.—The temperature is the same as on yesterday. The pulse has increased in frequency, and is now from 160 to 170 per minute. The respirations are from 70 to 80 per minute. Delirium is marked. The diarrhœa has ceased. The patient when roused up will take nourishment. Desquamation again begins on the abdomen. Death seems imminent. Notwithstanding the patient's condition her life was prolonged for four days, death occurring on the ninth day of the relapse.

During the four days since the last recorded observation, desquamation was rapidly accomplished. The heart's action grew more feeble from day to day, respirations became more embarrassed and frequent, delirium more marked, and the temperature remained at or above 105° F. up to a few hours before death.

Notwithstanding the fact that I had made a diagnosis of typhoid fever at the commencement of the attack, it was greatly shaken after the appearance of the eruption. Flint, in his late work, speaks of a "scarlatiniform" rash not infrequently occurring at the commencement of typhoid fever, and preceding the ordinary "rose spots." J. C. Wilson, in his article on enteric fever in the "Encyclopædia of the Diseases of Children," says: "An erythema-

tous rash is not infrequently observed in children, and even in adults with white delicate skins, during the first week, and it is usually most marked on the abdomen and flexor surfaces. Its usual duration does not exceed three or four days." After making a research of all the literature at my command, I am able to find but a few cases like the one I have presented. Scarlatina is not infrequently associated with enteric fever, but this was easily excluded for the following reasons:

First, the patient had had scarlatina once, six years before, and had not recently been exposed to that disease.

Second, the temperature is high from the beginning in scarlatina and rapidly reaches its maximum intensity. In typhoid fever there is a gradual rise in the temperature.

Third, the rash makes its appearance on the face and neck usually within the first forty-eight hours in scarlatina. In my case this did not occur until the sixth day of the attack, and it first appeared on the abdomen.

Fourth, the rash in scarlatina becomes rapidly confluent and when at its maximum the entire body is covered, the skin being uniformly red, hot, and dry and sometimes tense, swollen, very sensitive and œdematous, especially about the face and eyes. In my case the rash became slowly confluent and at its maximum intensity only on the abdomen and on the flexures of joints. Besides it was most marked on the flexor surfaces. The skin was not sensitive nor œdematous upon any portion of the body.

Fifth, the color of the skin in scarlatina is usually of a bright scarlet, and vesicles and pustules are rarely present. In my case the color was dusky red, and at times vesicles and pustules were abundant.

Sixth, in scarlatina redness of the faucial and buccal mucous membrane, with more or less angina and enlarged lymphatic glands, is almost invariably present. In my case none of these symptoms were observed.

Seventh, in scarlatina during the course of the disease at some time albumin may usually be found in the urine. In my case no albumin was present during the entire attack.

Eighth and lastly, in my case the eruption was present during the relapse, which is a very rare occurrence in scarlatina after convalescence has been established.

Variola was excluded by the fact that the patient four years ago had a violent attack of this disease, and by the time, appearance, and recurrence of the rash. There is no doubt that the eruption was scarlatiniform erythema, so rarely observed in typhoid fever.

When the rash had reached its maximum intensity I asked my friend, Dr. A. H. Ohmann-Dumesnil, to see the case with me. He concurred in the diagnosis of typhoid fever, excluding scarlet fever as a complication, and called the eruption "scarlatiniform erythema," believing with me that the exanthem was due to the typhoid poison, and apparently taking the place of the "rose spots" commonly seen in typhoid fever. This conclusion was arrived at for the following reasons:

First, the time of the appearance of the rash corresponds exactly with the usual time that these spots appear, namely, the latter part of the first week.

Second, appearing first on the abdomen, as the "rose spots" usually do.

Third, during the relapse the rash again appeared, as the "rose spots" generally do.

Fourth, the duration corresponded closely with that of the "rose spots," and the decline in the eruption was coincident with that of the fever. Therefore, we observe that the time of the appearance, duration, and recurrence corresponded closely with the history of the "rose-spots."

From the foregoing may we not be justifiable in assuming that this case is an atavistic form of typhoid fever? May we not assume that the eruption as observed was the original eruption of typhoid fever, and that during the course of time it has become so modified that we have now only the "rose spots" instead of a general erythema? I have no proof to offer in support of this theory beyond the fact that we know that in biology we constantly have recurring types presenting themselves, and we further know that diseases change, some epidemics are at times mild and at other times malignant, and we can offer no satisfactory explanation for these changes. By accepting this as the solution of the above and similar cases we must conclude that typhoid fever was originally an exanthematous disease.

Post-mortem.—Autopsy was performed twelve hours after death in the presence of Drs. George A. Krebs and G. W. Gale. Rigor mortis well marked, emaciation great, abdomen flat. On opening the abdomen we found the following: Peritoneum normal; intestines contained but little gas and fæces, through the ileum could be distinctly felt the thickened "Peyer's patches." The mesenteric lymph-glands were greatly swollen but none were broken down. On opening the ileum we found the mucous membrane somewhat hyperæmic. "Peyer's patches" very prominent; follicles enlarged and ulcerated. In some of the patches the healing process had nearly been completed, since the mucous membrane had evidently been regenerated, though they still remained thickened, while in other patches ulcers, having the characteristic punched-out edges, were still present. The mucous membrane in other portions of the intestines seemed to be perfectly normal. The spleen, liver, and kidneys were all enlarged.

I regret very much that we were not permitted to examine the lungs. The father had with much reluctance granted the post-mortem, and being present in the room would not permit us to open the chest.

No detailed mention has been made of the treatment adopted in this case. I followed the now almost universally adopted cold-water treatment, and my own views agree fully with those so clearly and convincingly stated by Dr. S. Baruch in a paper in the MEDICAL RECORD of February 16, 1889. For this reason the discussion of the therapeutic measures at this place seems to me uncalled for.

COMMERCIAL BUILDING, ST. LOUIS, MO.

THE ACTING ASSISTANT SURGEON OF THE UNITED STATES ARMY IN THE WAR OF THE REBELLION.

BY JOHN T. NAGLE, M.D.,

NEW YORK.

THE agitation which has taken place, for a couple of years past, to fix the status of the acting assistant surgeon of the United States Army, now serving, and give him the rank, pay, etc., of second lieutenant of cavalry, should be persevered in, as I feel quite sure that, if Congress could be made to understand his true position and the arduous duties he performs, that it would concede the modest request he makes. The MEDICAL RECORD has from time to time informed its readers of the almost humiliating position the acting assistant surgeon is now placed in. Some of them held, I am informed, medical commissions of high rank during the late war, and ought to deserve well of their country and receive the sympathy of every lover of justice. I sincerely wish them success in their movement.

The position of the acting assistant surgeon of the United States Army of the present day is pretty well understood by the medical profession, particularly that portion of it that is interested in military affairs; and as very little has been said of the acting assistant surgeon of the army during the late war, I think the following brief account may be of interest.

The Medical Staff of the United States Army.—The "Medical History of the War of the Rebellion," Part III., Surgical Volume, page 899, informs us that, at the outbreak of the rebellion, the medical department of the

United States Army was composed of one surgeon-general, with the rank of colonel; thirty surgeons, with the rank of major; and eighty-four assistant surgeons, with the rank of first lieutenant for the first five years of service; and that these medical officers formed a portion of the general staff of the army, and were not permanently attached to any regiment or command, but were subject to duty wherever their services were needed; and that at the beginning of hostilities, in 1861, large forces of State troops, or militia, responded to the several proclamations of the President calling for aid in suppressing the rebellion, and that each regiment was provided with a surgeon and an assistant surgeon, commissioned by the States in which the troops had been enlisted. These officers were borne on the muster-rolls, and permanently attached to the regimental organizations, being seldom detached except for urgent reasons. The calling out of a force of five hundred thousand volunteers, on July 22, 1861, necessitated an increased medical force to care for the wounded and disabled soldiers, and an act to reorganize and increase the efficiency of the medical department of the army was approved April 16, 1862. The organization of the regular staff was increased so as to number 1 surgeon-general, 1 assistant surgeon-general, 1 medical inspector-general, 16 medical inspectors, and 170 surgeons and assistant surgeons; there were appointed 547 surgeons and assistant surgeons of volunteers; there were mustered into the service, between April, 1861, and the close of the war, 2,109 regimental surgeons, and 3, 882 regimental assistant surgeons. During the same period there were employed 85 acting staff surgeons, and 5,532 acting assistant surgeons.

The Regular Army commissioned medical officers, the surgeons and assistant surgeons of United States Volunteers, and the Acting Assistant Surgeons of the United States Army, were not attached to any regiment or command, but were subject to duty wherever their services were needed, while the regimental surgeons and assistant surgeons were rarely detached from their regiments.

The laws of the United States prescribed the age of an applicant for the position of assistant surgeon to be from twenty-one to twenty-eight years, and no person who was under twenty-one years or over twenty-eight years could receive an appointment as an assistant surgeon in the United States Army. The regimental medical officers and the acting assistant surgeons were not limited to this age, but were required to be physically sound on entering the service.

The Acting Assistant Surgeon, how Appointed.—The acting assistant surgeon United States Army, or contract surgeon, in order to be appointed as such, had to make application to be examined for the position in the manner described in the following circular, issued by Joseph K. Barnes, who was acting surgeon-general of the United States Army, viz.:

"Information for applicants for the position of contract surgeon, in the United States Army.

"1. All candidates must make application in their own handwriting (accompanied by sufficient evidence of good moral character, of physical ability, and of being graduates of some regular medical college), to the surgeon-general at Washington, assistant surgeon-general at Louisville, or a medical director of a department.

"2. Upon the receipt of such application, a permit will be given for examination before the nearest medical board then in session, or before a board convened temporarily for that purpose by a medical director.

"3. If reported favorably by the board, the candidate will receive a certificate to that effect, which will secure him the position of contract surgeon whenever his services may be needed.

"4. In accepting a contract, the physician binds himself to serve the United States for a stated period, unless sooner discharged, and to be subject, in all respects, to the same control as all other medical officers."

Requirements and Duties of the Contract Surgeon.—The successful candidate is required to subscribe to a printed form of oath, which is administered to him, and he is now officially designated as acting assistant surgeon, United States Army. The duties of the acting assistant surgeon were similar to those of assistant surgeons and surgeons of the medical staff of the army. He wore the uniform and insignia of rank of assistant surgeon, and was allowed the same amount of pension that was given to a first lieutenant of the military or marine corps. He was assigned to commands, in the field and elsewhere, which were without medical officers. Many were assigned to the charge of United States general hospitals, where the responsibility was very great, and the executive officers of a very large number of the United States general hospitals were acting assistant surgeons.

Nearly all the United States hospitals for the care of the soldiers who suffered from small-pox, and other contagious and infectious diseases, were in charge of acting assistant surgeons of the United States Army. The following account of one of them, which was furnished by Dr. J. V. Patterson, of No. 104 West Penn Street, Germantown, Pa., who was an acting assistant surgeon, United States Army, in charge of the United States Hospital, near Philadelphia, is interesting and amusing. Dr. Patterson states that he was assigned to duty as acting assistant surgeon, United States Army, on August 21, 1862, and after serving two months, he states that it was determined to open a hospital for small-pox and other contagious diseases. Several regular army surgeons refused to have anything to do with it, and the medical director of the department requested him to open and organize such a hospital, which he did on October 7, 1862, and he remained surgeon in charge until August, 1865, when he closed up the hospital. He not only acted as physician, but he was obliged to serve as clerk, paymaster, etc. On account of small-pox patients, everyone fought shy of the hospital. The paymaster refused to come to the hospital, and he, Dr. Patterson, was obliged to make out the pay-rolls, and take them to the paymaster in the city of Philadelphia, and the paymaster, after eying them suspiciously, would draw his check for the amount. Of the officers sent from Washington to make an official inspection of the hospitals, there never was but one man who had the courage to enter the wards, examine the bedding, and make a thorough inspection. At the close of his term of service he had the satisfaction of being complimented by the medical director with the remark, that he had given him the least trouble of any surgeon in the department, and that the hospital fund had been so well managed that, on two occasions, he had drawn from its surplus to help to pay the debts of other hospitals.

On page 902 of the "Medical and Surgical History of the War of the Rebellion," Part III., paragraph 5, the following appears:

"As soon as possible after every engagement, the wounded were transferred from the division or corps hospitals to the base or general hospitals, which at one time numbered 205; these were under the charge and command of the regular or volunteer staff, assisted by acting assistant surgeons, medical cadets, and officers of the second battalion of the veteran reserve corps." This statement is not altogether accurate, as there were several United States general hospitals under the charge and command of acting assistant surgeons of the United States Army. The hospital railway transportation service was generally placed under the charge of acting assistant surgeons. Acting Assistant Surgeon J. P. Barnum fitted up the ambulance or hospital train for the transportation of the sick and wounded between Louisville and Nashville, a distance of one hundred and eighty-five miles.

"Surgeon George E. Cooper, U. S. A., Medical Director of General George H. Thomas's Army of the Cumberland, reported that when he arrived in the Department he found a train, fitted up by Dr. Barnum, already in operation on the line, one train, at least, leaving the vicinity

of the field hospitals daily. The trains were prepared under Dr. Barnum's direction, and Dr. Barnum states that he conveyed twenty thousand four hundred and seventy-two sick and wounded soldiers from the battle fields, general hospitals, etc., with a loss of but one man, who, despite the advice of his surgeons, implored that he might be taken to die in the bosom of his family. Dr. F. L. Town, U. S. A., in a report to Assistant Surgeon-General R. C. Wood, remarks that Acting Assistant Surgeon J. P. Barnum had charge of the first hospital train built at Nashville, and that he studiously labored to improve and systematize its working, and devised many expedients looking to the comfort of the patients in days when the theory of hospital trains was not so well understood as now" (see pp. 962–3, "Medical and Surgical History of the War of the Rebellion," Part III., Surgical Volume). Dr. Barnum states that he was with General W. S. Rosecrans' advance column, and participated in the battle of Chickamauga, and organized the Main Street Hospital in Chattanooga on Sunday after the battle. This hospital he turned over to Brigade Surgeon J. P. Arter, and took charge of the ambulances, which conveyed two thousand men from Bridgeport to Nashville. Dr. Barnum was afterward placed in charge of the river transportation of sick and wounded soldiers, having direct control of the steamer Mercury, where he not only acted as surgeon-in-charge, but also as post commandant, commissary, quartermaster, paymaster, and had authority to sign the name of R. C. Wood, Assistant Surgeon-General, by order of the Secretary of War; a power granted, he believes, to no other official of any rank in the Department.

Acting Assistant Surgeon Solomon A. Andrews was in charge of the ambulance or hospital train between Washington, Baltimore, and Philadelphia.

The acting assistant surgeon of the United States Army was subject to do duty wherever his services were most needed, in accordance with the United States Army regulations, and he was liable to be changed from one post to another at the will of his superior officers.

There were many very eminent physicians and surgeons in this branch of the medical service of the army, as the following extract from the "Medical and Surgical History of the War," Surgical Volume, Part III., page 901, entitled the Medical Staff, and prepared under the direction of General Joseph K. Barnes, Surgeon-General, United States Army, will show:

"Besides the medical officers of the regular and volunteer staff, and the medical officers of regiments, there was a class designated as acting assistant surgeons, who were private physicians, uncommissioned, serving under contract to do duty in the field or in general hospitals. This class was very large, and embraced in its number some of the most eminent surgeons and physicians in the country."

The acting assistant surgeon ought to be proud of the compliment paid him, as it was the only branch of the medical staff of the army that was singled out and received special mention on account of the eminence of some of the physicians and surgeons that were attached to his corps. The tribute, however, was well deserved. Professors in medical colleges, editors of standard medical works, and other physicians and surgeons of eminence, abandoned the comforts of home and sacrificed lucrative practices to share the dangers and discomforts incidental to camp life, because their country needed their services, and their patriotism and sense of duty to their country, and the sick and wounded soldiers who suffered in its defence needed the most eminent medical and surgical care that the country could give.

The orders that were given to the acting assistant surgeon were similar to those that were issued to other medical officers. I submit a few of those that were received by an acting assistant surgeon as examples of the form, to show that he was as strictly under military laws and discipline as the assistant surgeon of the regular army who he personated:

ORDERS.

MEDICAL DIRECTOR'S OFFICE,
WASHINGTON, D. C., June 23, 1864.

Acting Assistant Surgeon John T. Nagle, U. S. A., will report for duty without delay to Surgeon John Higgins, Surgeon-in-chief of the Cavalry Depot, Camp Stoneman, D. C.

J. V. D. MIDDLETON,
Assistant Surgeon, U. S. A.,
For Medical Director.

Through Assistant Surgeon C. A. McCall, U. S. A.,
Mt. Pleasant Hospital.

HEADQUARTERS CAVALRY DIVISION,
DEPARTMENT OF WASHINGTON,
CAMP STONEMAN, D. C., July 4, 1864.

DOCTOR: You will report for duty to the commanding officer of the second battalion, consisting of the third division and reserve brigade, which is to march to-morrow morning.

By order of WILLIAM GAMBLE,
Colonel Commanding.
A. HARD,
Surgeon-in-chief Cavalry Division,
Department of Washington.

JOHN T. NAGLE,
Acting Assistant Surgeon, U. S. A.

PASSES.

HEADQUARTERS MILITARY DISTRICT OF WASHINGTON,
WASHINGTON, D. C., July 2, 1864.

Pass John T. Nagle, acting assistant surgeon, U. S. A., to Camp Stoneman, Md., for the purpose of joining camp. This pass will expire July 2, 1864.

By order of M. N. WISEWELL,
Colonel and Military Governor.
WILLIAM H. ROGERS,
Captain and Aide de-camp.

No.....

OFFICE OF PROVOST MARSHAL,
SANDY HOOK, July 28, 1864.

Guards and pickets pass John T. Nagle, surgeon, to Harper's Ferry and return. Good for this day.

WILLIAM H. H. GONTZ,
Captain and Provost Marshal.

Pass no goods.

Several of the acting assistant surgeons served nearly during the entire war, and the "Medical and Surgical History of the War" shows that they performed their duty with zeal and fidelity, and that they never shirked any duty or responsibility imposed on them.

The following record of military history will show the form furnished to an applicant, who served in the late war, for a copy of his history, viz.:

Military history of Charles H. Bowen, M.D., as shown by the records of the Surgeon-General's office.

October 7, 1861, was appointed medical cadet, U. S. Army, and assigned to duty at the Infirmary, Washington, D. C. December 31, 1861, was transferred to Circle Hospital. January 4, 1862, ordered to report to Surgeon Cooper, at Port Royal, S. C. January 9, 1862, order rescinded, and was reassigned to duty at Circle Hospital. September 15, 1862, reports from Armory Square that his time is about to expire. October 8, 1862, entered into contract with the Surgeon General U. S. Army for duty as acting assistant surgeon U. S. Army, and was assigned to duty at Armory Square Hospital, Washington, D. C. November 24, 1862, was on leave of absence for six days. December 13, 1862, ordered to report to medical director's office, Washington, D. C., for temporary duty with the army of the Potomac. Returned December, 1862, to Armory Square Hospital for duty. April 19, 1863, contract annulled, and a new one made at an increased compensation. Remained on duty at Armory Square Hospital to November 11, 1863, when ordered to report to Surgeon J. C. McKee, U. S. Army, at U. S. General Hospital, Pittsburg, Pa.; was on duty at General Hos-

pital, Pa., to February 20, 1864, when his contract was annulled at his own request. Under contract April 8, 1864, was on duty at Chicago, Ill., to April 25, 1864, when contract terminated. Under contract dated May 10, 1864, was on duty at Armory Square Hospital, Washington, D. C., Fort Simmons and Mansfield, Lincoln and Armory Square General Hospitals, and U. S. engineer brigade, D. C., and at Slough General Hospital, Alexandria, Va., to November 11, 1865, when his contract was annulled at his request.

Official: C. H. CRANE,
Assistant Surgeon-General, U. S. Army.

SURGEON-GENERAL'S OFFICE,
December 4, 1889.

The "Medical History" further says: "Of the amount of labor performed by the medical staff during the war some idea may be obtained when it is stated that 5,825,480 cases of wounds and disease occurred among the white troops, and 629,354 cases among the colored troops. The total expenditure of the medical department to the close of each fiscal year, from June 30, 1861, to 1866, inclusive, was $47,351,982.24 (exclusive of salaries of commissioned officers) for the benefit of the sick and wounded soldiers of the nation." The report says: "It is a matter of just pride that it can be said that the medical disbursing officers performed their duties faithfully and honestly, and that the immense quantities of medical supplies distributed all over the country were, almost without exception, properly accounted for."

To the fidelity and efficiency of this vast body of professional men, the Surgeon-General, in his annual report of 1865, bears the following well-deserved tribute: "I desire to bear testimony to the ability, courage, and zeal manifested throughout the war by the officers of the medical department, under all circumstances and upon all occasions. With hardly an exception, they have been actuated by the highest motives of national and professional pride, and the number who have been killed or wounded bears honorable testimony to their devotion and duty on the field of battle."

Extraneous Duty of an Acting Assistant Surgeon.—Occasionally Acting Assistant Surgeons were called on to perform unexpected duties; for instance: At the battle of Kernstown, near Winchester, in the Shenandoah Valley, which took place in July, 1864, the Second Battalion, which consisted of the Reserve Brigade and Third Division of Cavalry, which left Camp Stoneman, July 5, 1864, was commanded by Colonel Samuel B. M. Young, who is now major of the Third United States Cavalry and Brevet Brigadier-General, United States Volunteers. Colonel Young was a gallant and brave officer, and was wounded and disabled while gallantly leading his men, and had to be removed hurriedly in an ambulance from the field, on account of the vigorous onslaught of the enemy. The fire became so hot that the men were driven back in confusion, the balance of the officers hurriedly left the field, and left the men to take care of themselves. Dr. John T. Nagle, who was an acting assistant surgeon in charge of this command, then took charge, rallied the men, and on the retreat spiked some abandoned guns, had the wheels removed from the gun carriages and caissons, and burned them with a number of baggage wagons to prevent them from falling into the hands of the enemy, and brought the men from the field in good order. The particulars of this engagement appeared in the *Army and Navy Journal* of June 22, 1889, headed "Battle of Kernstown," and in the New York *Mail and Express*, February 2, 1889, headed "Mulligan and his Men."

The particulars are also filed with the records of the command in the War Department, adjutant general's office, and also in the surgeon-general's office with the record of the services of John T. Nagle, late acting assistant surgeon, United States Army.

The fault of the acting assistant surgeon, United States Army, not having been legally mustered was not his; he wore the uniform of first lieutenant and believed that every one wearing the uniform was mustered, and so did every other person that he came in contact with; he was sworn into the service, and he is now confronted with the statement that he is not discharged because he never was legally mustered. Without finding fault with the apparent injustice done him, and without entering into any controversy on the subject, he simply asks to have his services recognized and his position acknowledged, so that he can profit by any benefits that might be attached to an "honorable discharge."

Incomplete and Inaccurate Record of the History of the War of the Rebellion.—The history of the war of the rebellion will be incomplete if the services of the acting assistant surgeons are not recognized with the commands they served with; and the omission of the services from the adjutant-general's office of the 5,532 acting assistant surgeons of the United States Army who served in the field, in charge of the railway hospital service, and in the United States general hospitals, is such an injustice to the medical officers mentioned, as well as to the American people, who are interested in the compilation of a true history of the war of the rebellion, that if for no other reason than to show that the soldiers received proper medical attendance, the bill recognizing their services ought to pass. The bill will in no way entail any expense to the United States Government, and will be a tardy recognition of the services and sacrifices that these eminent and hard-worked surgeons performed for their country during its hour of trial. The bill is as follows:

FIFTY-FIRST CONGRESS, FIRST SESSION, S. 1096.

In the Senate of the United States, December 11, 1889, Mr. Manderson introduced the following bill, which was read twice and referred to the Committee on Military Affairs:

A bill to fix the status of the acting assistant surgeons of the United States Army, or contract surgeons, who served in the war of the rebellion.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled. That all acting assistant surgeons of the United States Army, or contract surgeons, who served in the war of the rebellion, and whose services were honorably terminated, be commissioned as acting assistant surgeons of the United States Army, the date of contract to be the date of commission and muster into the service, and the date when the service was honorably terminated, or the contract annulled, to be the date of discharge or muster out of the service: *Provided*, That any expense attending the issuance of a commission as acting assistant surgeon of the United States Army be borne by the applicant for such commission: *And provided*, That no pay or allowance be made to any such acting assistant surgeon or contract surgeon by virtue of this act.

This bill was introduced in the United States Senate on December 11th, by General Charles F. Manderson, United States Senator from Nebraska, a brave and gallant soldier, who was wounded in the service of his country, and is numbered in the Senate as Bill 1096. It was introduced in the House of Representatives on December 18, 1889, by the Honorable Amos J. Cummings, member of Congress from New York, a well-known and brilliant journalist, who served as sergeant-major in the Twenty-sixth New Jersey Volunteers during the war. The bill in the House of Representatives is numbered H. R. 603.

Among those interested in this bill are many who were commissioned medical officers during the war, but who served as acting assistant surgeons, United States Army, during some period of the war of the rebellion. The following are some of those who are most actively interested:

L. S. TESSON, M.D., Fort Sidney, Neb.

H. A. ROBBINS, M.D., Surgeon, Kit Carson Post No. 2, and Medical Director, Department of the Potomac, G. A. R., 1226 Fifteenth Street, Washington, D. C.

William Balser, M.D., Surgeon, Koltes Post No. 32, and formerly Medical Director, Department of New York, G. A. R., 218 East Thirteenth Street, New York City.

John T. Nagle, M.D., formerly Surgeon of Post Sedgwick No. 11, Department of New York, G. A. R., 47 East Twenty-first Street, New York.

G. M. Bradfield, M.D., Surgeon of Post ——, G. A. R., Department of Philadelphia, Pa., 1236 Spring Garden Street, Philadelphia.

George E. Stubbs, A.M., M.D., 616 Walnut Street, Philadelphia, Pa.

James V. Patterson, M.D., 104 West Penn Street, Germantown, Philadelphia, Pa.

F. P. Pfeiffer, M.D., 222 North Second Street, Camden, N. J.

E. H. Klüber, M.D., Ellinwood, Barton County, Kan.

J. E. Brooke, M.D., Plymouth, Marshall County, Ind.

C. R. Reed, M.D., Middleport, O.

S. C. Ayres, M.D., 64 West Seventh Street, Cincinnati, O.

Thomas Morrison, M.D., formerly of the Army of the Cumberland, Wayne, Mich.

George M. Paullin, M.D., Shiloh, N. J.

T. O. Bannister, M.D., Odell, Ill.

J. H. Brownlow, M.D., 55 Caroline Street, Ogdensburg, N. Y.

Charles H. Bowen, M.D., 601 Massachusetts Avenue, N. W., Washington, D. C.

J. B. Crandall, M.D., Sterling, Ill.

N. A. Robbins, M.D., Fire Department, Brooklyn, N. Y.

Adolph Kessler, M.D., 644 Lexington Avenue, New York City.

J. O. Stanton, M.D., 1344 G Street, Washington, D. C.

Thomas G. Morton, M.D., 1421 Chestnut Street, Philadelphia, Pa.

J. P. Barnum, M.D., 543 Fourth Avenue, Louisville, Ky.

Robert J. Reilly, 3300 Meramac Street, St. Louis, Mo.

Clinical Department.

DEATHS FROM SNAKE-BITES.

By JAMES T. THOMAS, M.D.,

ALBXANDRIA, NEB.

The following is sent in answer to the request of Dr. H. H. Hopkins, in the Medical Record of October 17, 1889, for reports of cases where death resulted from snake-bite:

J——, an American boy, between four and five years of age, son of Philip T——, of Dakin, Neb., while coming home from school, with his older sister and other children, June 3, 1882, was bitten by a rattlesnake on the inner surface of the right foot, in front of and below the malleolus.

During the evening and night about one pint of whiskey was given him, which produced only slight symptoms of alcoholism. He slept about four hours during the night, and in the morning his father refused to have more whiskey given him. June 4th he ate a light breakfast, but about 9 o'clock was more restless, but not in much pain. The swelling in the foot began immediately, continuing unabated until death, at which time it extended from the foot to the crest of the ilium. The skin was cold, tense almost to bursting, and spotted. At 1 P.M. he called to his mother, saying there was not air enough in the room; he could not breathe. She immediately turned his face toward a window, he dying in the act. I was not an attendant, but was conversant with the case at the time.

Another case, which I believe to be a death from snake-bite, gives this history: A German boy, between four and five years of age, started to go to his father through an oats stubble field (a favorite resort for snakes) on an August day, 1888, but returned to the house, saying he had hurt himself, and in a short time was sick at the stomach, his foot pained him and began to swell, showing two scratches. The next day he was treated for erysipelas. On the third day from the first illness he died suddenly, with limb swollen up to body, spotted, and cold. There was no fever. These particulars were given by the boy's uncle within a week of his death.

I remember reading, a number of years since, in a Beatrice (Neb.) paper, of the death of a young man in October from a snake-bite in July. He was binding or shocking grain in the harvest-field, and while in the act of picking up his bundle was bitten on the arm by a rattlesnake. The bite received immediate treatment, but a slough formed, and things went from bad to worse; amputation was refused, and patient died.

In the first case, the chain of evidence is clear of a snake-bite June 3d, death June 4th, and previous good health. In the second, the history of good health is clear to the time of going into the stubble-field, the shock causing sickness and a drowsiness, which obtain in snake-bite and not in erysipelas. Death on the third day, with a limb swollen to, and including part of, the body, as an effect of erysipelas in two small wounds of foot, would be a startling history. Absence of fever, and the fact that there were no other cases in that vicinity, either immediately prior to or following this case, does not accord with our accepted theories of that disease; but if snake-bite is accepted as possible, there is nothing in the history to antagonize it.

On case three I make no comment, save that I have seen cases wherein such a termination was entirely within the line of possibility. While I am opposed to the whiskey treatment of snake-bite, I do not believe it responsible for any considerable amount of alarming symptoms. If there was no considerable disturbance of the normal condition, the result of whiskey would be "a plain drunk." All lay rules for administration of whiskey in these cases advise stopping at this point. From an observation of twenty-seven cases of snake-bite, within my own practice, I draw these conclusions. The primary effect of snake-bite is to cause nausea and drowsiness, from its action on the nervous system, and this within a short time. The secondary effect is destruction of tissue immediately surrounding the bite. I believe this secondary effect and its natural consequences to be the only danger to man in case of rattlesnake bite, and the controlling elements the power of resistance and rapidity or slowness of absorption in the individual case. To Dr. Hopkins' treatment I would suggest the use of a solution of permanganate of potassa to the bitten part as an addition only. It is the only drug I have much use for in snake-bite, and it is a success.

A MALIGNANT GROWTH IN A HERNIAL SAC (INGUINAL VARIETY) — OPERATION — RECOVERY.

By THOMAS H. MANLEY, M.D.,

NEW YORK

In the Medical Record of October 12, 1889, there appeared an article from the pen of Dr. Daniel Lewis relating a most unique and interesting complication of a hernia; and now, by a singular coincidence, I have, within a month, had another of those remarkable cases of cancer developing in a hernial sac; and as they are so rare and seldom met with, yet full of interest, I have deemed the case one well worth recording.

The history is briefly as follows: The patient came to Harlem Hospital on the evening of October 10, 1889, entering just as I was about leaving the hospital after my afternoon's clinic. He was an Italian, thirty years of age. He informed us that, fifteen years previously, after making a heavy lift, he felt a severe pain in his right groin, and immediately thereafter he saw a swelling, which still remained. This enlargement gave him no trouble until ten days before he came to the hospital, when, while lifting

a heavy stone into a wagon, he bruised the parts, and since had had no relief from pain.

On examination a swelling was found, of pyramidal form and stony hardness. It followed along the course of the spermatic cord in its upper part, and extended along upward into the inguinal canal. He was somewhat feverish, with quick pulse and coated tongue. His abdomen was tympanic and exquisitely sensitive. The bowels had not moved for four days, and on the day of admission he had vomited three or four times.

It looked as though he had a strangulated hernia; but there were many features in the case which would exclude it. Among these were the stony hardness of the swelling, and the fact, as we learned, that it was common for him to have his bowels constipated for several days at a time. Besides, it appeared that he had had the soreness in the abdomen since he was injured by the falling stone.

The enlargement might be due to an encysted hydrocele of the cord, or any one of the large variety of benign neoplasms.

Though the pathological character of the part affected was decidedly obscure, there could be no doubt that the man had much pain, which emanated from the affected location.

I was quite satisfied in my mind that he had a hernia, which was nipped somewhere along its neck by a constricting band.

I directed the house-surgeon, Dr. T. Currie, to do the operation, reminding him that if he found that there was no hernia, or that the parts had undergone such structural changes that he might be much embarrassed in the proceeding, then he must proceed no farther, but protect the incision with antiseptic dressings until I could go on with the operation myself.

I learned by telephone, an hour after I left the hospital, that the operation was begun, but owing to the condition of things met with it was discontinued.

The following day, at 11 A.M., I reopened the wound, and found beneath, and thoroughly incorporated with the coverings of an old incarcerated hernia, a new-growth, as hard as cartilage, extending from about four inches below directly into and through the inguinal canal. The tumor lay immediately over the spermatic cord, with which it was intimately adherent. It was evident from a most casual examination that our patient had had a hernia, and, owing to a badly fitting truss its coverings had taken on adhesive inflammation, and had soldered or fused everything in that situation into one mass.

In dissecting upward, following and stripping the growth of its coverings, I found that it extended into the peritoneal cavity. The mass consisted of omentum undergoing pathological changes. There was no strangulation of the bowel, though the neck of the growth, as it emerged from the internal ring, was bound firmly down till I released it by a free dissection. Now the mass was cut off on a line with the internal ring, and the operation completed by the McBurney method.

The operation was followed by immediate and permanent relief from pain. Dr. Ferdinand Kneer, of the Loomis Laboratory, very kindly made sections of the neoplasm and microscopical examinations for me. He reported that he found the mass to consist of a fibrosarcoma, the sarcous elements being derived from the connective tissue of the omentum. He further informed me that the diseased process commenced in the mass outside the ring, and thence, through the lymph-channels and blood-vessels, extended upward to the ventral cavity. Our patient has made a good recovery.

Dr. Lewis speaks of the liability of benign growths to take on malignant changes. That this does sometimes occur no one doubts; but does the doctor designate a protruded intestine or piece of omentum a tumor or growth? His case and mine were in no sense tumors. We know that malignant changes in the latter are common, but that the contents of a hernial bag would undergo this I never supposed until I read Dr. Lewis' very interesting report and encountered a case in my own hospital service.

302 West Fifty-third Street.

Progress of Medical Science.

The Surgical Treatment of Typhlitis.—From a paper by Dr. Treves, published in the *British Medical Journal*, we take the following: 1. The operation should not be performed until all inflammatory and other symptoms have quite subsided. 2. The incision should be made obliquely from above, downward and inward over the cæcal region, its lower extremity ending just external to the epigastric artery. The incision should not be made directly over the appendix or over the dullest region. If it be so placed a number of adhesions will probably be encountered, and the demonstration of the peritoneal cavity might be difficult. The cæcum or the appendix might be actually adherent to the anterior abdominal wall. The incising of the peritoneum should, therefore, be conducted with the very greatest care. It is well that the parietal cut should open the abdomen at a point just beyond the diseased area, and where no adhesions exist. 3. When the appendix and cæcum are exposed, the area of the operation should be cut off from the general abdominal cavity by sponges. If this plugging with sponges be well carried out, no blood should enter the peritoneal space. 4. All adhesions should be divided by cutting; none should be "broken down." The latter measure is apt to tear the bowel, or, at least, to bare it of peritoneum. 5. The appendix should be lightly clamped close to the cæcum, and should be divided about half an inch from that intestine; it should not be secured by a simple ligature. The mucous membrane should be united by many fine sutures, or by a continuous suture; then the divided outer walls of the process should be brought together by a second row of sutures; it is practically impossible to bring the serous coats together. To still further secure the orifice, the stump of the appendix might be lightly attached to any adjacent surface of the peritoneum. 6. The abdominal wound should be closed; no drain is required.

Action of the Liver on Poisons.—Dr. Roger points out that the liver modifies the toxic effects of several poisons, as has already been noted by Schiff, Hegar, Jacques, and Lautenbach. He has performed certain experiments which demonstrate clearly its modifying action with regard to nicotine, atropine, quinine, and strychnine; also certain putrid and intestinal poisons, peptones, and some salts, particularly ammoniacal salts. On the other hand, the liver exercises no influence over other substances, such as digitaline, some salts (potash and soda), glycerine, etc. The liver, therefore, like the kidney, possesses an elective action. To control these results it is necessary that the poison should be absorbed very slowly. In the case of a diseased liver (cirrhosis, fatty degeneration, etc.), in which the parenchyma no longer contains glycogen, the liver does not act on poisons, but it suffices to administer substance capable of forming glycogen to see the hepatic gland again competent to transform poisons. The action of the healthy liver is continually exerted against toxic substances in the system, it is still more marked in those infectious diseases in which decided toxic effects are produced. Some clinical facts go to prove that many morbid symptoms are due to insufficiency of the liver in regard to poisons.—*The Provincial Medical Journal.*

Does Salting Meat Destroy Bacteria?—Professor J. Forster, of Amsterdam, has published an account of some investigations made in his laboratory by himself and De Freytag, having for their object the determination of the effect of the common process of salting or pickling meat on various forms of bacteria. It was found that cholera bacilli were soon destroyed under the influence of abun-

dance of salt, usually in a few hours; but that typhoid bacilli, pyogenic staphylococci, the streptococci of erysipelas, and the bacilli of porcine infectious diseases frequently retained their vitality for several weeks, or even months, in spite of the presence of abundance of salt. The same was also true of the bacilli of tubercle. In some cases these bacilli were found alive after being two months in pickle, their vitality being proved by their capacity for infecting new cultures. Portions of the viscera of a tuberculous animal, preserved for a considerable time in salt, were found capable of causing tuberculosis in a healthy animal when introduced into its peritonea, cavity. Experiments on the spleen of an animal which had died of malignant anthrax showed that salt possessed the power of destroying the bacilli of this disease in about eighteen hours. These, as well as cholera bacilli, were found to require seven and one-half per cent. of salt to destroy them. From these facts it would appear that salting or pickling has but little destructive effect on many of the more common forms of bacilli liable to be found in diseased meat.—*The British Medical Journal.*

Iodoform Oil in Tuberculous Affections of Bones.—Iodoform oil is at present used in Germany for treating tuberculous affections of joints and bones. This oil is injected into the affections of joints and bones. This oil is injected into the tissues just like a solution of iodoform in ether, which, however, has been given up for reason of its extreme painfulness, and of its occasionally causing gangrene. A twenty per cent. mixture of iodoform with olive-oil, prepared fresh for each injection, is used. Part of the iodoform will decompose if this mixture is kept for some time, such decomposition being easily found out, as it causes a reddish-brown coloration; 30 to 45 minims of this mixture are injected every eight days, on different places, by the aid of a Pravaz syringe. Previous careful disinfection of the skin is advisable.—*The Provincial Medical Journal.*

Operative Treatment of Carcinoma of the Tongue.—Dr. Krause reports statistics derived from all cases of carcinoma of the tongue operated on at Professor Volkmann's clinic in Halle between the years 1875 and 1888. Of the 91 cases operated on there is only a mortality of twenty-two per cent. due to the operation (*The Annals of Surgery*). In no case has there been any phlegmonous inflammation of the deep cellular tissues of the neck. As regards the technique of the operation, Volkmann has completely abandoned the ligation of the lingual artery as the first step in the operation, for even when the linguals are tied the hemorrhage is much greater than by the method he now employs. Tamponing of the trachea is also condemned as dangerous, for in Volkmann's opinion tracheotomy is not so harmless a procedure as it is generally supposed. Two methods of operation are employed in the clinic at Halle, according to the position, size, and extent of the carcinoma. If the tumor can be drawn as far forward as the teeth, by means of a hook or fillet, the new-growth is simply removed with the knife and scissors. (Under these circumstances there is no danger of the blood entering the larynx; the patient, deeply narcotized, is seated upon a chair during the whole course of the operation.) The hemorrhage being arrested, the wound is united, or if only a small piece of the healthy side of the tongue is left, this is turned back and united to the stump, leaving the patient with a shorter but broader tongue. In cases where the tumor is too far back to be drawn out sufficiently, or if the disease has invaded the floor of the mouth, the palate, or tonsils, Volkmann employs Langenbeck's procedure of lateral section of the lower jaw. The patient is chloroformed in a half-sitting posture, and the tongue is drawn forward by means of a loop or tenaculum. The canine and first molar teeth are then extracted, if needed, and a vertical incision is made from the angle of the mouth down to the larynx, cutting through to the periosteum of the jaw, above, but below only dividing the skin. The periosteum is then removed from the inferior maxilla and the bone sawed through with a flat saw. Then both parts of the bone are strongly pulled apart, and all the soft parts of the floor of the mouth are then cut in the line of the first incision. This affords ample space to remove any of the infiltrated glands which may be present, and for ligation of any bleeding point. The anterior palatine arch is always cut through, and a drainage-tube is introduced into the niche of the tonsil and brought out externally and terminates about the level of the larynx, thus preventing the secretions and fluids from gaining access to the trachea. After removal of the diseased part, the tongue is sutured, and the whole wound closed by the sutures if possible; if not, iodoform gauze tamponade is employed. The edges of the bone are united by a silver-wire suture. As regards the after-treatment, the patient is placed in a semi-reclining posture, and is fed by fluids which are poured into the back of the mouth by means of a vessel with a long neck. The majority of patients operated on are able to swallow even a few hours after the operation, or at the latest on the following day. After each meal the mouth is washed out with some harmless antiseptic solution, usually boric acid. This mode of operation is, according to the writer, satisfactory in every respect, and it affords a large field for operation, and is attended with only slight hemorrhage. During the operation the flow of blood into the trachea is absolutely prevented, since the epiglottis is always in sight, and is situated on a higher level than the wound. The secretions from the mouth and wound are afforded a free exit through the drainage-tube. The mortality after such an extensive and radical operation is not very high, only 2 deaths in 35 cases. In 56 partial extirpations of the tongue, done between 1875 and 1888, there were no deaths.

Methyl Chloride as a Local Anæsthetic.—Dr. Ernst Feibes, draws attention to the extensive and successful use in the Paris hospitals of methyl chloride as a local anæsthetic. Methyl chloride (CH_3 Cl) is a colorless, easily liquefied gas, with an odor resembling that of ether and chloroform. The readiness with which the gas liquefies adapts it for convenient use, as it can be stored in a siphon, or in a bottle of any size specially constructed to conduct heat badly. It may be applied to any surface directly from the siphon, or as a spray, but this method is objectionable, owing to the anæsthetized area not being in most cases sufficiently circumscribed. Bailly uses the following method, which he calls "stypage:" Tampons composed of cotton-wool, surrounded by a layer of flock-silk and then covered with thin silk, are saturated with methyl chloride, and applied to the part by means of wooden or vulcanite holders. After contact for some seconds, the part gets pale and anæmic, and diminishes in sensitiveness. If the tampon be then removed there is marked reaction, shown by congestion and slight itching; but if the application be continued for a short time longer (a few seconds) the skin assumes a white, dried, parchment-like appearance. This is the time to operate. If you proceed further, superficial necrosis may result. The application is sometimes succeeded by itching and an urticaria-like eruption. It is employed in all kinds of small operations—circumcision, opening abscesses, and in neuralgia, lumbago, muscular pains, gout, etc. In scraping lupus it is best applied by means of a camel's-hair brush, as special parts can then be anæsthetized with perfect precision.—*The British Medical Journal.*

A Modern Malthus.—Mr. Drysdale has some very radcial ideas on the need of limiting the population of the world. He thinks that it is the duty of governments to discourage large families, and proposes that a tax be levied on every child in families where the number of children exceeds four. "A bill to encourage infanticide" would not be apt to meet with a very favorable reception in most legislatures at the present time, however popular it might become in the year, say, 2000.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, February 1, 1890.

INFANT FOODS AGAIN.

THERE is still no medical problem much further from satisfactory solution than that of infant feeding. Not but that much progress has been made, both scientifically and practically. But it is still true that in public institutions nearly all young infants artificially fed die. And it is still a fact that eminent specialists in children's diseases quite disagree as to what is the best kind of food for infants. Some praise sterilized milk, others think highly of crown wheat and certain infant foods, or of cream and diluted milk, or milk and barley-water.

An interesting and profitable illustration of this fact is seen in the two articles on infant feeding which were read before the American Pædiatric Society last summer.

Dr. Arthur V. Meigs holds strongly to the view that human milk contains a smaller amount of casein than is usually believed to be the case, viz., about one per cent. He favors, therefore, first, the dilution of cow's milk, and then the addition of cream, sugar of milk, and lime-water. His directions are as follows: "One quart of good ordinary milk is placed in a high pitcher, or other vessel, and allowed to stand in a cool place for three hours; then one pint is slowly poured off from this, care being taken that the vessel is not agitated, the object being to obtain the upper layer of fluid, rich in fat, and leave the lower, comparatively poor, portion behind. When the child is to be fed, there are taken of this weak cream three tablespoonfuls, of lime-water two tablespoonfuls, and of sugar-water three tablespoonfuls. The sugar-water is to be made in the proportion of eighteen drachms of milk-sugar to one pint of water. This makes only four ounces of food, and if the infant is old enough to require eight ounces at once, double the quantities of each of the ingredients must be mixed. This is simply warmed in a bottle, as usual, and is then ready for use."

After the discussion upon Dr. Meigs' paper, Dr. J. Lewis Smith contributed the results of his experience in baby feeding, giving an interesting history of the extraordinary mortality that used to occur among bottle-fed babies in the Foundling and Infant Asylums of this city.

Dr. Smith lays down the following preliminary propositions:

1. Mothers who are capable should nurse their infants until the age of ten or twelve months.

2. Good wet-nurses are preferable to bottle-feeding; but good wet-nurses are hard to get.

3. Animal milk should be the basis of all artificial foods.

4. Animal milk, *i.e.*, cow's milk, contains an excess of casein and is hard for infants to digest. This can be overcome by sterilizing the milk, by peptonizing it, or by adding to it some farinaceous substance like barley flour.

5. Infants cannot digest starch easily, but can digest starch after it is converted into glucose and dextrine by the action of diastase or prolonged heat.

6. Food which is entirely predigested should not be systematically and continuously given to infants.

Dr. Smith, working on the above principles, prepares a food for infants as follows: Milk is obtained from a trustworthy source; it is sterilized. Barley flour subjected to boiling heat for seven days is used as the farinaceous element; and the following directions are given: "Add a heaped tablespoonful (nearly two even tablespoonfuls) of the flour to eighteen of cold water, which has been boiled. The gruel may be brought to the simmering point, to facilitate the admixture. For infants over the age of six months, in ordinary health, six tablespoonfuls of the sterilized milk and six of the gruel may be mixed for one feeding. Salt should be added until it can be tasted.

"For infants between the ages of three and six months, and for those older than six months who have symptoms of indigestion or gastro-intestinal catarrh, it is advantageous to peptonize the milk. Five tablespoonfuls of milk, two of the barley flour, two of water, and the peptogenic powder as much as fills the small measure which accompanies the powder should be mixed and heated six minutes with constant stirring, but not at a temperature too hot to be sipped. The food thus prepared should be fed to the infant at intervals of three hours, or, if it be hearty and fretful, at intervals of two and a half hours."

The inquiring practitioner will feel still somewhat in the dark after reading the above descriptions of baby foods. If he pursues his investigations, he will find other highly recommended combinations, and if he begins to investigate the baby foods on the market his mind will get in a delirious whirl of unexceptionable and emphatic medical testimonials.

There seems to be but one conclusion to be drawn from the experience so far gathered, and it is that each baby must be treated individually and empirically, and the food best adapted for it given. In many cases the foods described above cannot be prepared without great inconvenience or expense, and there are babies who will thrive on neither but who will do well on some other artificial food.

We do not wish to disparage the formulas given by Dr. Meigs and Dr. Smith. They undoubtedly represent foods which have a wider range of application than almost any others; but no single artificial food seems yet to have been devised which will be the best for all babies. The tendency of professional opinion is decidedly to do away with the artificial baby foods so extensively put upon the market, and in which so much money has been invested that some babies have got to take them in order to support the corporations.

A DIPLOMA-SELLING RING.

The Boston *Globe* has a long and sensational article purporting to be obtained from a member of a ring dealing in medical diplomas. This man states that the business of selling diplomas is well organized and systematically carried on. The work began about forty years ago, and has been continued steadily ever since. There are, he states, about fifty men in this country now engaged in the business, and a somewhat less number in Europe. There are fifteen or twenty medical colleges, so called, which sell their diplomas at a price ranging from $25 to $150. It is estimated that there are seven to eight thousand of these bogus diplomas now in this country, and nearly thirty thousand in Europe.

We are inclined to think that the story is mostly an idle fabrication.

WHERE A NEW DISPENSARY IS ACTUALLY NEEDED.

On the occasion of the laying of the corner-stone of the new Eastern Dispensary in this city, the distinguished divine, Dr. John Hall, made an address in which he said "it was only necessary to look around at the buildings of the neighborhood to be satisfied of the necessity for such a public charity as the Eastern Dispensary. He praised the work of those who had kept up the dispensary, and concluded by saying that, with God's blessing, it would continue to be a practical benediction to the poor."

How would these remarks apply to the dispensary of the Presbyterian Hospital, surrounded as it is by palatial residences and in a portion of the city noted for the wealth of its inhabitants. But probably we need dispensaries for the rich as well as for the poor, the same as with our churches, of which we are told the dispensaries are the efficient helpers.

Last year, 61,228 patients were treated at the Eastern Dispensary, and the doctors made 106,748 visits and consultations. There was an average daily attendance of 420 persons, all poor and needy. How do these results compare with those of the expensive plant up-town?

With the Vanderbilt clinic on the west side the case is somewhat different, as it was established for the purpose of supplying clinical material for the College of Physicians and Surgeons and Roosevelt Hospital, and of course, an interesting case, rich or poor, must be made available.

Solvine is the name of a new substance formed by mixing sulphuric acid and castor-oil, removing the excess of acid, dissolving the residue in water, and treating a precipitate, which gradually falls, with a mineral acid. The resultant liquid is of a clear yellow color and of an oleaginous consistence. The substance possesses very marked solvent properties, and passes readily through animal and vegetable membranes, being therefore absorbable by the skin. It is said to dissolve the red blood-globules when injected hypodermically, and is thus not to be regarded as a very safe substance for use in ointments. Indeed very pronounced toxic symptoms are reported to have followed the application of a solution of naphthol and solvine to the mucous membrane. Berlioz, who presented the substance at a recent meeting of the Therapeutical Society in Paris, proposed to call it sulphoricinic acid.

News of the Week.

Professor T. Gaillard Thomas' Book Translated into Chinese.—It is a matter for much congratulation to notice the influence which American medical literature is exerting in different parts of the world. The most recent example of the sort is the translation of Thomas' "Diseases of Women" into the Chinese language, to be read in true antipodal fashion, upside down, but always able to hold its own, nevertheless. Our distinguished townsman, since the first appearance of his admirable treatise, has been doing a great deal of missionary work, and through the different translations into German, Italian, French, and Spanish, he has gained a deservedly large and appreciative audience; but to carry his doctrines literally to the ends of the earth leaves nothing to be said concerning their influence, truth, and power.

Dr. James P. Lynde, of Springfield, Mass., died January 21st, aged sixty-one years.

The Medical and Surgical Society of Baltimore.—At the annual meeting of the Medical and Surgical Society of Baltimore the following officers were elected: *President*, Dr. H. T. Rennolds; *First Vice-President*, Dr. David Street; *Second Vice-President*, Dr. E. J. Williams; *Recording Secretary*, Dr. J. Wm. Funck; *Corresponding Secretary* and *Treasurer*, Dr. Wm. H. Norris; *Executive Committee*, Dr. D. W. Cathell, Dr. R. W. Mansfield, Dr. J. W. Chambers.

Brown-Séquard's Elixir will perhaps take a new lease of life. The venerable discoverer of it has come again with further facts in its favor and a new method of taking it, viz., by rectal injection. In the *Archives de Physiologie normale et pathologique*, Dr. Brown-Séquard cites the results of some very exact experiments made by Dr. R. Suzor, of the island of Mauritius. The experiments were made upon two lepers, who, after an injection of testicular juice, showed striking improvement in nervous and cutaneous symptoms. Dr. Brown-Séquard cites a case of impotence cured by the injections.

Death of Sir W. W. Gull, of London.—Sir William Withey Gull, M.D., died in London, January 29th, after a second stroke of paralysis. He was physician in ordinary to the Prince of Wales, and was knighted in recognition of distinguished services to the Prince during 1871, when his Royal Highness had an attack of typhoid fever at Sandringham.

Reduced Fare for Delegates to the State Society.—The fare for delegates throughout the State of New York will be at the rate of a fare and a third for the trip. Ticket agents along the line will supply certificates, which must be signed by Dr. Curtis on arrival in Albany. Delegates from this city may apply to Dr. Ralph Waldo, 215 W. Twenty-third Street. The meeting is to be held in Albany Tuesday next.

Dr. Sidney Allen Fox is the name of the gentleman referred to in our last issue as taking part in the discussion on Expert Testimony before the Kings County Medical Society, and not Dr. Sidney Allen as reported.

Professor Botkin, one of the best-known physicians of Russia, died on December 24th.

Obstetric Section, New York Academy of Medicine.—At a meeting of the Obstetric Section of the Academy, held January 23d, the following officers were elected: *Chairman*, Dr. Egbert H. Grandin; *Secretary*, Dr. I. H. Hance.

Clinton County (N. Y.) Medical Society.—At the annual meeting Dr. J. G. McKinney was elected president for the ensuing year.

Insane Asylum Fire.—The insane asylum at Worcester, Mass., caught fire on the night of January 19th. All the patients were safely rescued. Damage, $6,000.

The Grady Hospital at Atlanta, Ga.—Atlanta has decided to build a city hospital to be named after Mr. H. W. Grady, for which over $45,000 is now on hand. The hospital is to be for the equal accommodation of both white and black patients.

To Stop Unwelcome Visitors.—The Pennsylvania State Board of Health has notified the Scranton Board that about three hundred Norwegians suffering from typhus fever have just been landed from the steerage in New York, and that a number of them are booked for this city. A meeting of the Scranton Board of Health was held to take necessary action in the matter, and Dr. Allen, the health officer of the city, was instructed to keep a sharp lookout for the visitors.

Severely Burned in a Laboratory.—While F. M. Miller, a medical student of the University of Pennsylvania, was working in the pathological laboratory yesterday afternoon, he attempted to pour some alcohol into a lamp which he thought was not lighted. Mr. Miller was immediately enveloped in a mass of flames. Drs. Formad and Smith and several of the students came to his rescue, and succeeded in extinguishing the flames. Mr. Miller was badly burned about the face and head.

Schenectady County (N. Y.) Medical Society.—Dr. George E. McDonald was elected president for the ensuing year.

Dr. William F. Peabody, one of the oldest and best known physicians on the Pacific slope, died on January 27th, at San Francisco, aged seventy-three. Dr. Peabody was born in New Hampshire, but acquired his medical education at the University of Maryland.

The Treatment Was Proper.—Willie Kelly's suit against Dr. Robert A. Black, of Brooklyn, N. Y., for $25,000 damages for the alleged improper treatment of a broken arm, ended January 27 in a verdict for the defendant. The jury was out only half an hour, and the result may be viewed as a complete vindication of Dr. Black, and a legal triumph for Lawyer J. J. Leary. Professor Jarvis Wight and Professor E. A. Lewis, of the Long Island College Hospital, and Dr. L. P. Schenck, of the Kings County Hospital, testified that the treatment of the arm, as shown by the plaintiff's own testimony, was proper, and that in their view nothing had been left undone so far as the surgical treatment was concerned. Two things, it was shown, were necessary in such a case; a proper setting of the bone and complete rest. It was shown that the boy was seen playing on trucks with his bandaged arm, and jumping off sheds, and that he fell on the stair of the Brooklyn Theatre when trying to get past the ticket-taker.

Small-pox in Mexico.—Small-pox prevails in Mexico, and quarantine has been declared along the Texas line.

Surgeon-General J. B. Hamilton has gone to Havana to investigate the yellow fever.

The Ills of Our Eminent Confrères.—Our exchanges tell us that Dr. Brown-Séquard has the whooping-cough, Professor Bergmann has just had pneumonia, and Professor Westphal is incurably ill.

The Abolition of the Title of "Doctor."—The *Boston Medical and Surgical Journal* says: "We notice in a lay exchange a racy argument in favor of the abolition of the no longer distinctive title of 'doctor,' as applied to the medical profession." The argument first appeared in the editorial columns of the RECORD, which we trust is not seriously regarded as "a lay exchange."

Floods and Their Results from a Sanitary Standpoint.—Arrangements have been made to hold a Tri-State Sanitary Convention at Wheeling, W. Va., February 27 and 28, 1890. Representatives will be present with papers and addresses from Pennsylvania, West Virginia, and Ohio. The object of the convention is to consider the question of floods and their results from a sanitary standpoint, and the best methods of managing the sanitary interests of a given community after such a calamity. Owing to the mutual relations held by these three States with reference to large rivers, and the numerous towns in each one of these States that are annually affected by floods and their results, it has been thought wise to hold a convention for studying how best to manage the sanitary interests of cities and towns so affected. Every person interested directly or indirectly in this important subject is earnestly requested to be present and assist in discussing the papers, and add whatever information he can to the solution of these practical and most important questions, affecting as they do the health and lives of thousands of citizens of these three great commonwealths annually.

Fees in New York.—The professional fees in New York City are not so extravagant as they are generally believed to be. The general practitioner averages from two to five dollars per visit, according to pecuniary condition of patient. The average fee for visit to the wealthy is five dollars. The office consultation of an expert or general consultant is, as a rule, ten to twenty-five dollars for the first visit and five to ten dollars for succeeding ones. The fee for a consultation visit varies with the reputation of the consultant and the ability of the patient, from ten to twenty-five dollars. Visits out of town are usually from ten to twenty dollars per hour of absence from home, plus the travelling expenses and regular consulting fee of twenty-five dollars. Surgical operations are rated according to character, time, skill, and range, from 100 up into the thousands. The operation fee is charged for as extra of that for time when away from home. Night calls are twice the amount of day services, whether ordinary or consulting visits. Notwithstanding these accepted rules, there are not a few here who can charge much higher fees—in fact, name their own price and get it. On the other hand, there are many younger men in the profession who are content to average a dollar a head for every patient they see, whether in their office or on the top floor of a six-story tenement in the rear. This is true, although we would not like to have it repeated.

Waterbury Hospital.—Waterbury, Conn., has a new hospital, with a full medical staff, a fuller board of managers, and a consequently wide range of usefulness.

Curing More than He Kills.—The Mexicans have no confidence in a young doctor until he has had a couple of years practice. Then they make an inventory of his patients, and if he has cured more than he has killed they recognize him, no matter whether he has a diploma or not.

Medical Society of the County of Kings.—The sixty-ninth annual meeting of this society was held in Brooklyn, on the 21st ult., and the following officers elected: *President*, Dr. W. B. Chase; *Vice-President*, Dr. Frank H. West; *Secretary*, Dr. William M. Hutchinson; *Treasurer*, Dr. Charles N. Cox; *Librarian*, Dr. J. H. Hunt; *Censors*, Drs. Glentworth R. Butler, Z. T. Emery, F. D. Bailey, J. W. Hyde, George W. Brush; *Trustee*, Dr. A. Ross Matheson, and *Delegate to the State Medical Society*, Dr. Ernest Palmer. The librarian reported over eight hundred additions to the library of the society, and two hundred medical journals in the reading-room.

A Child born with the Measles.—Dr. Lomer, of Hamburg, reports a case where a mother gave birth to a child while suffering from measles, it being the second day of the eruption. The child when born showed the beginnings of a measles rash, and subsequently developed the disease in its typical form.

Permission for the Surgeon to Operate.—Medical circles in Belgium, says *The Lancet*, have been considerably excited recently by the trial of an action against a well-known surgeon who is on the staff of a hospital in Liège. More than two years ago a child was brought to the hospital for the advice of the surgeon in question on account of a curvature of the tibia. The mother was told that an operation would be necessary, to which she replied that she must obtain the grandmother's consent. Shortly afterward the child was brought back to be operated on. Unfortunately gangrene supervened, and the child's leg had to be amputated. After the lapse of some two years the father of the child appeared on the scene, and, declaring that his consent to the operation had not been obtained, commenced an action against the surgeon for having operated without it, the result being that the court awarded him ten thousand francs damages as compensation for the loss of the child's leg. The case has been appealed.

"Too Previous" in Practising.—A medical student of the University of Pennsylvania was recently reprimanded by the coroner for practising without a diploma.

Tobacco and the Dog.—The public apparently does not tire of sensational reports of the dreadful and impossible effects of tobacco. We now hear that the French Anti-Tobacco Society has just issued a work calling attention to an alleged new danger attached to the use of the weed. Experiments have been made to determine the effect of tobacco-smoke upon meat and vegetables ready for cooking or prepared for the table, and the result has indicated that the smoke under such circumstances deposits all its poisonous qualities in the food with which it comes in contact. A piece of rare meat, after being exposed for some time to tobacco-smoke, was offered to a dog, who refused to touch it. It was then concealed in some palatable covering, and the dog ate it, and died in a short time. An autopsy showed nicotine-poisoning to have caused death. Poor dog! This is on the dog side of the question if this report is true. But, seriously, what will these fanatical cranks have us believe next?

Reviews and Notices of Books.

HYGIENE AND PUBLIC HEALTH. By LOUIS PARKES, M.D. 12mo, pp. 471. Philadelphia: P. Blakiston, Son & Co. 1889.

THIS popular compend is mostly adapted to the comprehension of non-professional readers, though some mathematical formulæ are retained. The information here given certainly cannot have too wide a circulation. How to select the climate of our habitation, how to construct, plumb, and drain our houses, how to eat and drink, and what to wear—these and all cognate topics are the first concern of every intelligent being.

We have read this book with great interest, and find that it covers pretty nearly the entire ground of hygienic science, much of the material being very newly acquired knowledge, and such as should be extensively promulgated. These facts about every-day affairs come home to us all. Take, for instance, the almost universal practice among bakers of putting alum in bread. Who that has to eat at a New York restaurant does not know to his sorrow that sawdusty, puckery bread? Alum, says our authority, though it improves the appearance of bread made from poor flour, forms with phosphorus in combination an insoluble aluminium phosphate. Take again sulphuric acid as a substitute for vinegar. This acid forms an insoluble sulphate of lime.

Much space is necessarily given to the germ theory of disease. The author inclines to the view that the *modus operandi* of zymotic diseases is that the microbes cause the formation of a poison, though he admits the difficulty of accounting, on this theory, for the immunity from infection when diseased meat is thoroughly boiled before eating, as such boiling would not dissociate these organic poisons.

Where there is so much to commend, a few words of criticism may be allowed.

Dr. Parkes is certainly wrong in saying that bacteria are of the animal kingdom. All bacteriologists may classify them under *algæ*.

The literary style of the book is good in the main, but we notice frequent use of the adverb between the two component parts of the infinitive mood; also we find twice *viri* as a plural of virus.

1. HYPNOTISM, ITS HISTORY AND PRESENT DEVELOPMENT. By FREDRIK BJÖRNSTRÖM, M.D., Head Physician of the Stockholm Hospital, etc. Authorized translation from the second Swedish edition, by BARON NILS POSSE, M.D., Director of the Boston School of Gymnastics. Published by the Humboldt Publishing Co., New York.

2. AN EXPERIMENTAL STUDY IN THE DOMAIN OF HYPNOTISM. By DR. VON KRAFFT-EBLING, Professor of Psychiatry and Nervous Diseases in the Royal University of Gratz, Austria. Translated from the German by CHARLES G. CHADDOCK, M.D., Assistant Professor, Northern Michigan Asylum. Pp. 129. New York and London: G. P. Putnam's Sons.

THE phenomena of hypnotism have from time immemorial been more or less associated with charlatanism and chicanery. Simulation and dissimulation are so easy and so plausible that when, a century ago, the committee appointed to investigate the question presented their report, signed by the great names of Franklin, Lavoisier, Jussieu, and Bailly, wherein they said that "Magnetism is one fact more in the history of human errors, and a great proof of

the power of imagination;" this report was generally acquiesced in as embodying the ultimate conclusion of science.

Facts are stubborn things, however, and it is now conceded that there is a residuum of fact, notwithstanding all that is false and fraudulent, in these phenomena; and a potency for good or evil is involved which calls for careful study and scrutiny.

To define the real nature of hypnotism is as difficult as to explain the philosophy of toxic or therapeutic action of medicine—more so, indeed. None the less, however, does it behoove the practitioner to understand what it does, even if he cannot tell just what it is, or how it operates.

Dr. Björnström's book aims to give a general review of the entire subject, while Dr. Krafft-Ebling merely gives an account of a very remarkable case under his own observation. The former gives his opinion that it should be dealt with by the legislature, like deadly poisons, and none but regular physicians allowed to practise it.

Outlines of the Clinical Chemistry of Urine. By C. A. MacMunn, A.M., M.D. Philadelphia: P. Blakiston & Co. 1889.

This is a well-written book of two hundred and fifty-one pages, resembling a good deal Tyson's well-known work on the same subject. Although it is not intended to take the place of the more comprehensive books, like those of Salowski and Leube, it will prove a valuable guide to practical urine testing. The directions for the different manipulations are clearly described; but the author has but little to say concerning the relations of the abnormal ingredients to clinical medicine. There is a chapter on Urinary Calculi, and there are a number of very good drawings of the urinary deposits.

The Cerebral Palsies of Children. By William Osler, M.D., Baltimore, Md. Philadelphia: P. Blakiston & Co. 1889.

In this monograph, based on a study of one hundred and fifty-one cases of cerebral paralysis in children, which have already been published in the *Philadelphia Medical News*, July 14 to August 11, 1888, Dr. Osler contributes an excellent study of the etiology, symptoms, and treatment of this condition, together with many references to its literature. In regard to its etiology, we note that in nine of his cases injury from the use of forceps seems to have been the cause. The pathological lesions in these cases are various, but the majority are either hemorrhagic, post febrile, embolic, endo- and peri-arterial changes, and encephalitis or thrombosis of the cerebral veins. Treatment depends, of course, very much upon the nature of each individual case.

A Handbook of Physical Diagnosis of Diseases of the Organs of Respiration and Heart, and of Aortic Aneurism. By R. C. M. Page, M.D., Professor of General Medicine and Diseases of the Chest in the New York Polyclinic, etc. New York: J. H. Vail & Co. 1889.

This book cannot help being of great assistance to students and recent graduates in their studies in physical diagnosis. Dr. Page's experience as a teacher has taught him exactly their wants.

The style is throughout clear and logical, and each subject is for the most part fully treated; but a little more detailed description of the manner of production of the various râles and heart murmurs would have been of advantage. With few exceptions, his views coincide pretty closely with those most commonly accepted, but in classifying phthisis, a tubercular and non-tubercular variety are given. If we would regard phthisis as essentially a tubercular process, and then use the term interstitial pneumonia in place of fibroid phthisis, much endless confusion might be averted.

The section on Consumption contains a summary of conclusions reached by the Congress for the Study of Tuberculosis, held in Paris, 1888. The seven beautifully colored plates greatly enhance the value of the work. For those who want a good book on Physical Diagnosis, we can cordially recommend this one.

The Story of the Bacteria. By T. Mitchell Prudden, M.D., New York. Pp. 138. New York: G. P. Putnam's Sons. 1889.

In this little book Dr. Prudden gives us a most interesting description of the bacteria and the rôle which they play in nature. Without going into intricate details, which concern only the practical worker, and without the use of technical terms, and withal in an exceedingly clear and simple way, the story of the bacteria is told, so that the intelligent lay reader cannot fail to obtain an excellent general understanding of this most important subject.

Bacteria are being so much talked about nowadays and so many queer notions are held regarding them, and they are, after all, of so much practical importance, that a correct idea of their nature will lead to much public good.

After describing their form, mode of growth, and some of the non-pathogenic bacteria, those of the more important and better understood varieties are discussed, and their relations to our every-day life clearly pointed out. Although intended for the benefit of the lay reader, physicians will find this book instructive. There is no longer any excuse for one remaining in ignorance of this department of our science, and to a more extended acquaintance in bacteriology this manual will serve as a pleasant introduction.

Lectures on Bright's Disease. By Dr. Robert Saundby, Edinburgh. Pp. 282. New York: E. P. Treat. 1889.

Although the author claims nothing new or original, this book gives us an exceedingly good review of our knowledge of Bright's disease.

In Section I. the more prominent symptoms are discussed, particularly albuminuria and the changes to be observed in the retina. The more recent physiological experiments are detailed, and a number of well-observed cases are introduced. Appended to each chapter is a valuable bibliography.

Section II. is devoted to the clinical examination of urine.

Section III. is on Bright's disease proper. Saundby classifies his cases on an etiological basis under three heads: febrile, toxæmic, and obstructive; the first including all cases of acute or chronic nephritis occurring as a result of acute or chronic febrile disease; the second, those due to lithæmia; and the third, those resulting from obstruction to the outflow of urine. While such a classification may be useful for clinical purposes, we prefer to adopt the one of Dr. Delafield (already published, in the Medical Record) as being more satisfactory and less apt to lead to confusion.

The author's treatment is mainly symptomatic, and we agree with him that we possess no drug by which we are directly able to effect a diminution of the amount of albumin in the urine.

A Text-book of Animal Physiology, with Introductory Chapters on General Biology and a Full Treatment of Reproduction. By Wesley Mills, M.A., M.D., L.R.C.P. (Eng.), Professor of Physiology in McGill University, etc. New York: D. Appleton & Co.

It has long been apparent that for the successful study and teaching of human physiology, the comparative method, the early and full consideration of embryology, and the thorough recognition and application of the principles of evolution are most essential. The practice of simple enumeration of a number of more or less isolated facts, partly derived from observations on man and partly from various groups of animals, in a series of chapters or lectures, without co-ordination and comparison of the lower with higher forms of life—a method too often

pursued in teaching human physiology in medical schools —will in large measure explain the lack of interest in this science on the part of the average medical student. It will explain also his tendency to consider physiology as one of the things to hurry through and get disposed of, instead of one of the most fundamental and important of the disciplines, upon which day by day his future success as an intelligent practitioner and man of science will largely depend.

A book so permeated with the scientific spirit, so broad in its scope, and withal so clear and terse in its treatment of difficult themes, as is this new work of Dr. Mills, is difficult to review in detail without more space than is at our disposal here, or to speak of in general terms without exposing one's self to the charge of extravagant praise.

Gleaning his facts as he does from all parts of the broad and ever-widening domain of biological lore, and observing a most admirable caution in drawing inferences from lower to higher forms of life, physiology under this author's treatment really assumes, as from its nature it ought to do, a most fascinating and instructive aspect. Altogether apart from the knowledge, fully abreast of the times, which may be derived from this book, its value as a means of training the mind in the scientific method should secure for it an immediate recognition and an extensive use in medical schools.

For the rest, the book is liberally illustrated; the detailed treatment of each theme is followed by a terse summary of the more important facts elicited, while by here and there calling his attention to the bearing of his physiological studies on certain pathological conditions, the author keeps the student in touch with the ultimate purpose of his preliminary work, and under a stimulus which he must be very dull to resist.

Ventilation and Warming of Buildings. Pp. 154. Toledo, O.: Isaac D. Smead & Co. 1889.

This is a brochure devoted to the advocacy of the principles of warming and ventilating designed and patented by Isaac D. Smead.

The axiom of chief importance, according to the system, is that promulgated by a Mr. Ruttan, many years ago. Mr. Ruttan's theory affirms "that the point of exit for foul and cold air from a room should be *at* or *below* the floor-level, instead of, as then supposed, at the *top* of the room; and that a large volume of moderately warmed air should be supplied, instead of a small quantity of hot air."

Ingenious and obviously correct as is this theory of Ruttan, the latter did nothing toward carrying it out in practice. Indeed his failure to do so is readily accounted for when it is borne in mind that he was eighty years old when he published his book on the subject of ventilation and warming.

The credit of carrying out the various delicate points connected with the practical elaboration of this scheme belongs, apparently, to Isaac D. Smead, of Toledo, O., who has devoted years of study to the subject, and whose apparatus, in its perfected form, has been introduced into a large number of important buildings, both public and private.

The book is suggestive, and will repay a perusal, quite irrespective of its obvious commercial character.

Diphtheria: Its Nature and Treatment. By C. E. Billington, M.D.; and Intubation in Croup and other Acute and Chronic Forms of Stenosis of the Larynx. By Joseph O'Dwyer, M.D. New York: William Wood & Co. 1889.

Works upon diphtheria are sufficiently common the world over. Good ones, however, are rare. The authors of this are such well-known and popular authorities upon the subject that the expectations of the reader will be considerably excited. Fortunately, moreover, they will be fully realized. It is but fair criticism to characterize this treatise as the most useful one of its kind, in any language, which has thus far appeared. The book has as its basis the various excellent monographs which have been presented by Dr. Billington during the past fifteen years. These, however, have been thoroughly rewritten, greatly amplified in scope, a large amount of new material added, and, better still, the views contained in them have been verified by experience both long-continued and remarkably wide in extent.

Such chapters have been added as were necessary to complete the work, including an appendix upon the subject of intubation of the larynx. A successful attempt has been made to avoid overloading the book with unnecessary matter, as well as to present a clear and succinct statement of those facts in existing knowledge which are most essential to the formation of an intelligent opinion as to the nature of diphtheria itself, and of those therapeutical principles and details, the understanding and application of which will enable the physician to meet it with best results.

The book is divided into twelve sections, each one of which is deserving of special mention. When it is considered that 110 pages are devoted to the subject of "treatment," the great practical value of the work will be understood. In this chapter—following the presentation of the general indications, principles, and results of treatment, and the modes of employing remedies—is given a long series of subsections, in which all of the remedies and measures approved at the present time are presented. The methods and their application are explained in detail, the opinions of those advocating them fairly presented, and, in most instances, the results obtained from their use by the author frankly stated.

The appendix, upon intubation, is a clear and able exposition of the most recent methods and views of Dr. O'Dwyer relating to the performance of that admirable procedure, which, in common with its distinguished advocate, has become so justly famous.

The book contains 325 pages, and is illustrated by thirty-four wood-cuts and four excellent colored lithographs. Its mechanical execution leaves nothing to be desired.

In short, the authors are to be congratulated upon having presented a contribution which can hardly fail of receiving from the careful reader the highest praise; while by the busy practitioner who requires a work to which he can make hasty reference, with the certainty of finding advice at once full, clear, authoritative, and of the highest value, it will be welcomed as an invaluable aid.

Syphilis und Auge, nach Eignen Beobachtungen. By Dr. Alexander. Pp. 234. Wiesbaden: Verlag von J. F. Bergmann. 1889.

As medical director of the ophthalmological establishment at Aix-la-Chapelle, Dr. Alexander has been in an exceptionally favorable position to study the ravages of syphilis about the eyes.

Some idea of the comprehensiveness of this excellent monograph may be gleaned from a perusal of the various subjects treated of in the ten chapters of which it is composed. These are: General statistics; manifestations of syphilis in the eyelids; in the orbits and lachrymal apparatus; in the cornea and sclera; in the iris, the corpus ciliare, and the choroid; in the retina and optic nerve; in the muscles of the eye; and in impairment of the functions of the n. facialis and n. trigeminus. The two concluding chapters are devoted to hereditary sypnilitic affection of the eyes, and the treatment of diseases of the eyes of syphilitic origin. Though a number of monographs have already appeared, dealing more or less thoroughly with syphilitic affections of the eyes, it is safe to say that there is room for Dr. Alexander's work, which is written with painstaking attention to details, both as regards diagnosis and pathology. The chapter on treatment is also written in a practical spirit, and serves to terminate the discussion in a satisfactory manner.

Outlines of the History of Medicine and the Medical Profession. By Joh. Hermann Baas, M.D. Translated, and in Conjunction with the Author, Revised and Enlarged, by H. E. Henderson, M.A., M.D. New York: J. H. Vail & Co. 1889.

This work contains a vast amount of information, more or less reliable, on a very interesting subject, and one, moreover, which is too much neglected by medical men of the present day; for a knowledge of the errors of the past might have prevented some at least of the absurd blunders which have from time to time been committed by modern medical practitioners, and which are doubtless to be committed in the future. The book is divided into two sections, the first being devoted to a consideration of the medical culture of those nations whose development in medicine is either already closed or is stationary, and the second being taken up with the history of more modern medicine. The second section is the more interesting, since in it we are able to trace the progress of the art of healing from the times of the ancient Greeks and Romans down to the actual present. The author is evidently thoroughly familiar with his subject, and it is therefore all the more to be regretted that he must be set down as an unreliable historian. He allows his hostility to Christianity to warp, or rather to form, his opinions to such an extent that his trustworthiness as an impartial historian is very seriously to be questioned. The facts reported may be as stated, but the conclusions drawn from them are so evidently pre-formed that they raise (we might almost say justify) a fear that the facts may have been moulded to fit them. The translator has corrected some inaccuracies in the author's text, and also disclaims any sympathy with Dr. Baas' silly rage against everything relating to religion; but we are sorry that he has not devoted himself to the introduction to English readers of a better book.

Electricity, and the Methods of its Employment in Removing Superfluous Hair and other Facial Blemishes. By Plym. S. Hayes, A.M., M.D., etc. Pp. 128. Chicago: W. T. Keener. 1889.

The title of this little book sufficiently explains its object. For those in search of practical instructions on how to remove facial blemishes it will render good service.

A Text-book of Practical Medicine, Designed for the Use of Students and Practitioners of Medicine. By Alfred L. Loomis, M.D., LL.D., Professor of Pathology and Practical Medicine in the Medical Department of the University of the City of New York; Visiting Physician to Bellevue Hospital, etc. Eighth Edition, Revised and Enlarged. With two hundred and fifteen Illustrations. New York: William Wood & Co. 1889.

The popularity of this work is shown by the appearance of the eighth edition within five years of the first, and that it is a well-deserved popularity no one who has carefully examined the book will gainsay. The arrangement is similar to that of other treatises of the kind, and as would be expected in a work which attempts to cover the whole ground of medical practice in about 1,100 octavo pages, the treatment of each subject is somewhat condensed. This is, however, far from being a fault in the busy age in which we live. There is an absence of the "padding" which abounds so plentifully in many special treatises, and each article is as short as its importance permits, so that no time is lost in getting at the pith of the matter. In addition to an introduction in which the subjects of inflammation, hypertrophy and atrophy, degenerations, tuberculosis, and bacteriology are treated of, there are six sections, dealing respectively with diseases of the respiratory organs, of the digestive system, of the heart, blood-vessels, and kidneys, and of the nervous system, and with chronic general diseases. The illustrations are excellent and helpful. A good chromo-lithographic plate, showing several forms of pathogenic bacteria, is a valuable addition. We know of no better book of its kind for the student, or for the general practitioner who may have been unable to keep up with the rapid advance of modern medical science.

The Physician Himself and Things that Concern his Reputation and Success. By D. W. Cothell, M.D. Ninth edition, revised and enlarged. Pp. 298. Philadelphia and London: F. A. Davis. 1889.

It is given to few writers of advice to their professional brethren to meet with such a reception as that which has been accorded Dr. Cothell. The "candid friend" may be both honest and useful, but it cannot be said that his popularity keeps pace with his fidelity; indeed, it must be confessed that in most of his manifestations he is but too apt to be regarded as a nuisance, as his candor interferes altogether too much with that complacency of the soul which arises from blissful obliviousness to one's own faults. As Captain Marryatt puts it: "A man may damn his own eyes, but has no right to exercise a similar prerogative over other people's visual organs." Dr. Cothell, however, infuses so much of downright good-nature into his homely philosophy that one is rather amused than otherwise in discovering one's own psychological blemishes between the lines of his excellent discourse.

A book of this sort, with all its wealth of shrewd observations boiled down to concrete rule must do good. The practice of medicine makes a thousand petty demands—the more the pity—upon the patience and tact of the average practitioner. To be made aware in advance of possible pitfalls is to confer a distinct benefit, especially upon those members of the profession whose intellectual endowments fit them rather for the scientific and ideal walks of professional life than for those little policies which pertain to its commercial side. "The Physician Himself" should be on the book-shelves of every doctor's office.

Manuel Pratique de la Garde Malade et de l'Infirmière. Published by Dr. Bourneville, with the assistance of the following collaborators: Messrs. Blondeau, De Boyer, Ed. Brissaud, Budin, H. Duret, P. Keravol, G. Maunoury, Monod, Poirier, Ch. H. Petit-Vendol, Pinon, P. Regnord, Sevestre, Gollier, and P. Yvon. Fourth edition. Paris: Bureau du Progrès Médical. 1889.

After drawing attention to the fact that training-schools for nurses have existed for a number of years in the United States, England, and Switzerland, Dr. Bourneville alludes to the efforts which he made with a view to establishing similar institutions in France. At length these endeavors were crowned with success, and schools of this class were opened at the Salpêtrière and Bicêtre.

Thus far everything had gone well. Soon, however, it was found that there was an entire dearth of that simple literature so necessary to those who are bent upon the mastery of the more general principles of medical science.

It is to meet this want that Dr. Bourneville conceived the idea of publishing a series of manuals dealing more especially with those medical topics a knowledge of which is essential to the nurse who aspires to fulfil the highest possibilities of her calling.

The first volume of this little library treats of the more important points of anatomy and physiology; the second gives an account of the administration of several of the great hospitals of Paris—notably of the Hôtel Dieu and La Pitié; the third presents practical directions for the transportation of the injured, the treatment of wounds, and the application of bandages and splints; while the fourth and fifth books are devoted to the consideration of such themes as child-birth, the care of the new-born child, management of the insane, and administration of remedies. The entire series is well conceived, and we congratulate the hospital authorities of France on the possession of such a practical guide to the various duties involved in the scientific care of the sick.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION IN SURGERY.

Stated Meeting, December 9, 1889.

ROBERT ABEE, M.D., CHAIRMAN.

Rare Form of Shoulder Dislocation.—DR. CHARLES A. POWERS presented a young man with a rare form of shoulder dislocation, with the following history: The injury was sustained three years ago, the right arm, the patient states, being drawn into a wringer which he was operating in a public institution; at the same time the shoulder and whole side were forcibly drawn against the machine. He complained to the surgeon of the institution, who ordered him to return to work. The accident was followed by some deformity, and considerable pain and swelling at the shoulder-joint. Three months afterward the surgeon placed him under ether, and, the patient says, returned the arm to its place, but that it slipped out again, and his condition has since remained as it is to-night. The right humerus is the seat of anterior dislocation, the head of the bone lying in front of the glenoid cavity. When the elbow is raised the head of the bone can be made to undergo an excursion upward and inward above the coracoid process, and can be made to rise completely above the clavicle. When the arm is drawn down, and the elbow approximated to the side and drawn a little forward, the head of the bone can be pressed very nearly into the glenoid cavity. The functions and sensation of the arm remain nearly perfect. Abduction takes place when the scapula is fixed proximately to forty or fifty degrees. As one palpates the head of the humerus he feels that it is smaller than its fellow. As he grasps it with the fingers he can pass entirely around it. Internal rotation is practically complete; external rotation, however, is short, the greater and the lesser tuberosities can be plainly felt, and beneath the head, on the inner surface of the shaft, at about the site of the upper part of the surgical neck, there is a very distinct bony ridge. It would seem that he has had at all times since the accident an anterior dislocation of the humerus, that the rent in the capsular ligament is very large, the head of the bone can be slipped back through it fairly well, and it is a question whether there has been a fracture through the head or the neck of the bone. Two or three surgeons who have seen him, do not quite agree on this point. It is not thought desirable to operate.

Accidents in Internal Urethrotomy.—DR. GEORGE E. BREWER read a paper on "Accidents, Complications, and Results following Internal Urethrotomy upon 120 Cases of Stricture." As introductory to his paper he outlined the history of one of his earlier cases, which presented an unusual number of alarming complications, and afforded a most satisfactory example of the successful result of treatment. A man, aged forty, unmarried, called in December, 1886, suffering from an acute specific urethritis. He stated that he had not been free from a urethral discharge for seven years, that he had been treated by dilatation on several occasions by distinguished surgeons in England and America. The duration of his present acute attack was four days. Dr. Brewer treated him by hot retrojections some forty days, with but moderate success. After the acuteness of the attack had subsided, an examination revealed the presence of three dense fibrous bands of stricture in the anterior urethra, reducing the calibre at these points from 32 to 24 F. They were divided, the patient being under the influence of ether. The incision was made upon the floor of the urethra, and was immediately followed by alarming hemorrhage, which necessitated for its control the introduction of a full sized sound and the employment of external pressure during more than an hour. Retention of urine followed, relieved six hours after the operation by silver catheter. Shortly after catheterization the patient had a severe chill, followed by high fever. Next morning, as a result of trying to pass his water, extensive urinary infiltration took place into the subcutaneous cellular tissue of the penis. To these complications was added on the second day an unusually acute urethritis. By the faithful employment of measures mentioned later, the patient made a complete though tardy recovery, the only additional inconvenience being the presence of an annoying curvature of the penis on erection, which persisted about ten weeks. Three months from the date of the operation the patient was entirely well, without the slightest trace of a discharge. During the year he contracted acute specific urethritis twice, and was cured on each occasion, within eight days, by retrojections of hot water. Two years from the date of the operation he was still well, calibre of urethra throughout being 32.

Subsequent experience led him to believe that, had the operation been deferred for a longer period after the acute attack, had the incision been made upon the roof of the canal, and had no instrument been passed through the deep urethra, all, or nearly all, the complications could have been avoided.

The one hundred and twenty cases operated upon by him during the past four years included all kinds, good and bad, and were included in the tabulated list. The operation in each instance was undertaken for the relief of certain symptoms which were thought to be directly or indirectly traceable to the stricture. In all but three a distinct history of gonorrhœa was obtained. In one of the other three there had been excessive masturbation, in one lithæmia was present. In but three instances was the normal calibre of the urethra found to be below 30 mm. in circumference, and these occurred in individuals exhibiting also arrested development in other portions of the body. The average size had been about 33 F. The number of strictures in each case varied from one to seven. In all but one instance they were confined to the anterior urethra, or that portion between the meatus and the bulbo-membranous junction. The exception was in a patient who had a dense fibrous stricture in the membranous portion of the urethra, together with several bands anteriorly, which necessitated the combined operation of external and internal urethrotomy.

In all cases in which the stricture was at, or within three-fourths of an inch of the orifice, the operation consisted in an incision made with a straight, blunt-pointed bistoury on the floor of the canal; when the stricture was more deeply situated than this, dilating urethrotomy by means of the Otis dilating urethrotome was practised, the cut being made on the roof of the urethra. There was but one exception to this rule, already referred to. Cocaine was employed for anæsthesia in 116 cases, ether in four, in which there was great nervous irritability.

Regarding the after-treatment, it was found that the passage daily of a full-sized sound to the bulbo-membranous junction, during the first four or five days, was by far the most comfortable for the patient, as the pain attending its passage was always more marked and the hemorrhage more severe after the cut surfaces had been allowed to glue together for two or more days. A sound was usually passed also on the seventh, fourteenth, and twenty-first days after the operation. In cases where an acute urethritis followed the operation, or where the urethra was for any other reason abnormally sensitive, the daily passage of the sound seemed often to increase the severity of the symptoms, and in these cases the intervals were increased to three or four days. Cocaine was rarely employed during the passage of sounds in the after-treatment. Where dilating urethrotomy had been practised the patients were kept in bed until the danger from hemorrhage had passed—from three to five days.

If recontraction of the stricture was to take place, it was usually possible to detect a tendency to this within fourteen days of the operation. When this was found

further use of the sound was abandoned, both on account of the severe pain caused by forcing a full-sized sound through an imperfectly divided and recontracting stricture, and also on account of the utter uselessness of attempting to prevent recontraction by means of dilatation. After the cut from the first operation had healed, a second, deeper incision was made, with a view to completely severing the cicatricial band, upon which seemed to depend the only possibility of a radical cure.

If after three weeks the urethra had healed and there was no evidence of recontraction of the strictures, the use of the sound was discontinued, unless the presence of granular patches, an irritable deep urethra, or other similar conditions called for its employment. The use of sounds for an indefinite period after an operation, with a view to keeping the stricture open he regarded as wholly unnecessary. If a strictnre was to be cured by urethrotomy it must be by thorough division, which did away with the necessity for prolonged after-treatment by dilatation. Among the symptoms complained of by the patients, which were supposed to be caused directly or indirectly by the strictures, were, gleet, 92 cases; frequency of micturition, 11; disturbance of sexnal function, 13; spasm of the cut-off muscle, 6; chronic prostatitis, 6; neuralgia, 4, which was located chiefly in the genito-crural nerve, and in one in the sciatic; chronic prostatic discharge, 3; dribbling of urine, 1.

Among the unfavorable complications likely to occur as a result of this operation he first mentioned severe hemorrhage. This took place in 6 of his cases, in 3 primary, in 3 secondary. In its treatment it was rarely necessary to use other measures than rest and gentle pressure on the orifice. Epididymitis occurred in 2 cases, and followed the passage of a sound through the deep urethra. An acute urethritis followed the operation in 10 cases, in 7 of which the operation had been undertaken shortly after an acute attack of gonorrhœa, some of the gonococci probably remaining. A slight ecchymosis took place in the skin of the penis in the vicinity of the cut in 4 cases, and in 3 of these there was subsequent curvature of the penis on erection. Of the remaining 116 cases curvature was present in only 2. Where ecchymosis took place the incision must have been unnecessarily deep, extending through the urethra. Slight inflammatory thickening of the tissues at this point, or the presence of an organized blood-clot, might account for the curvatnre. It was treated by inunctions of oleate of mercury, with massage, and by the galvanic current. Massage made on a full-sized sound with inunction was most useful. Six months to a year was likely to be required before complete cure resulted.

Of 30 cases re-examined after from two months to three years, in 21 the urethral calibre remained normal. Of the 93 who had gleet, 51 were relieved, 11 unrelieved, 28 result not known.

In his conclusions the author expressed the view that the treatment of stricture of the anterior urethra by urethrotomy was a safe procedure; that by the intelligent application of a few well-known measures, alarming hemorrhage could in nearly all cases be avoided; that, with the exception of the meatus, the practice of dividing anterior strictures on the floor of the urethra should be condemned as a dangerous procedure; that the passage of instruments through the deep urethra should, if possible, be avoided immediately after the operation; that in a majority of cases, by complete division of all the stricture bands a radical cure could be expected; that all attempts to prevent recontraction in imperfectly divided strictures by means of dilatation were useless.

The Chairman referred to the infrequency of extravasation of urine in urethral stricture, compared with fifteen years ago, and to neuralgia, saying that he believed reflex neuralgia due to urethral stricture had not received the attention it should; he had, himself, seen two cases of this nature. He then called upon Dr. Otis to open the discussion.

To the Full Size of the Canal.—Dr. F. N. Otis expressed great satisfaction with the paper. The conclusions drawn were entirely warranted by his own experience, and the method of operating, he need hardly say, was such as he had advocated and successfully practised for nearly twenty years. He believed others would find as Dr. Brewer had, that a studious experience would lead them to do the operation more thoroughly and with more careful attention to details than it was their custom to do in the beginning. In regard to the extent of the incision in dilating urethrotomy, he believed that it should rarely stop short of complete division of the strictnre band. There were cases in which the deposit of stricture tissue was so great that it would be impossible to cut through it entirely, but such cases were very rare. Certainly one was warranted in making the division up to the full size of the canal, as indicated by the proportionate relation existing between it and the circnmference of the penis.

Regarding curvature of the penis after the operation, he had seen it occasionally, but was not inclined, with Dr. Brewer, to attribute it to deep incisions. He had seen it where he was satisfied that the incision had not extended to the fascia surrounding the corpus spongiosnm. It usually lasted but a few days, and rarely more then a few weeks. Its removal was hastened by massage, through the method of Dr. Hartley referred to by Dr. Brewer. The curvature sometimes gave way with a sensation like a slight snap during coition, slight hemorrhage following. This seemed to point to adhesions of the mucous membrane to the underlying tissues as a cause. He thought that the paper of Dr. Brewer would prove an encouragement to those who sought to effect a radical cure of stricture, as opposed to palliative measures through long-continued dilatation. He had not been able to find, in any work by an accepted authority, a single case recorded where stricture was even claimed to have been cured by gradual dilatation. For continued relief by this plan the use of sounds was necessary for the lifetime of the patient. Persons suffering from stricture should be relieved from this bondage and from the grave perils inseparable from it. This was shown to be possible only through complete division of stricture.

Dr. F. B. Sturgis congratulated the anthor upon the success which had attended urethrotomy in his hands. With regard to the safety of the operation, he believed it was always attended by a certain amount of danger, greater or less according to the instruments used. Dr. Otis's urethrotome was usually employed, and, with due respect to the inventor, he must say that incision with it combined with dilatation was dangerous, because the incision was liable to be too deep, especially when it was made on the floor of the urethra. Moreover, there was danger of hemorrhage, not only into the corpus spongiosum, as stated by Dr. Brewer, but into the whole urethra. The upper incision with the Otis instrument was the only one which should be made. He agreed with Dr. Otis, that the curvature was not always due to the depth of the incision, although it might be sometimes. The curvature would nearly always disappear, although he had seen one case in which it had lasted two years. Regarding hemorrhage, he had seen more than one case in which it forced its way back into the bladder, and was even alarming.

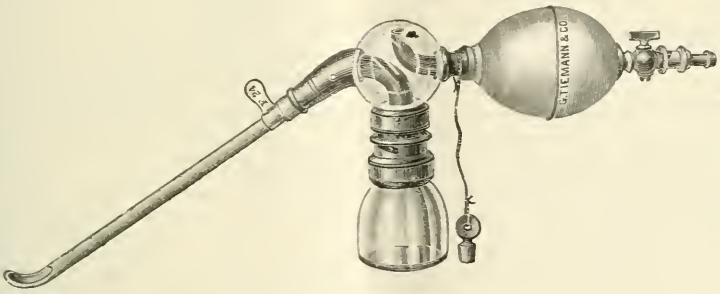
Dangerous in Acute Attack of Urethritis.—He agreed with Dr. Brewer that it was dangerous to operate during an acute attack of urethritis. When kidney disease existed internal urethrotomy should not be performed. He did not pass a sound until the third or fourth day after the operation, and in his experience hemorrhage was no more likely to occur than if it were passed the day following the operation, as practised by Dr. Brewer; urethral fever he thought was less likely to occur. He did not believe the full benefit of the sound was obtained unless the instrument was passed nearly the full length of the urethra, nor did this practice render urethral fever or cystitis more liable. Regarding recontraction, he agreed with the author, that it was due to in-

complete division; also that the operation was not curative, but only one step in the direction of cure. The real disease lay behind the stricture, and required further treatment. He continued to pass the sound oftener than Dr. Brewer, but he thought as he did, that if recontraction was to take place it would manifest itself usually the first month. He had known cases operated upon by Dr. Bumstead in which there had been no recontraction within ten years.

He did not believe that every stricture needed cutting. Some cases would get well by dilatation. The sound was counter-irritant and produced absorption of the stricture-tissue.

He did not know why rapid dilatation should have gone out of vogue. That it did split the mucous membrane at the site of the stricture had been shown at post-mortem in one of his cases, in which kidney trouble carried the patient off. He was inclined to perform rapid dilatation in preference to internal urethrotomy even in the pendulous portion of the urethra, regarding it as safer, and the subsequent results in his hands had been good.

In some Cases Complete Division Impossible.— Dr. A. G. Gerster wished, before commencing to speak on the merits of the paper, to say that when he came to this country, fifteen years ago, he was opposed to the treatment of stricture as taught by Dr. Otis, but it was not long before he became a complete convert to that method in preference to dilatation, practised in Germany. He was glad, however, to hear the admission from Dr. Otis that there were some cases of stricture in which complete division was impossible. Any amount of massage and dilatation of some cases of hard, callous, fibrous strictures, extending deeply into the peri-urethral structure, sometimes even involving the skin, would not effect a cure, nor would any form of internal urethrotomy. Where the stricture was not so deep, complete division of the stricture bands was possible and necessary. Why should not absorption of the newly-formed stricture material, which had not yet become hard and fibrous, take place after division and massage, as in newly-formed tissue at the seat of bone fracture? He believed with Dr. Sturgis, that where in a new stricture the tissue had not undergone fibrillary change a cure might be effected by dilatation and massage. In practice, however, he preferred to operate, as the most rapid method of effecting a cure. Besides, he considered internal urethrotomy a safe operation under proper precautions. He had seen dangerous hemorrhage but once, in which instance he attempted to divide a stricture extending through the corpus spongiosum. The patient, however, recovered. He thought it best to wait five, six, or even seven days in some instances, before passing the sound. He had never seen epididymitis after passing a sound. He attributed exemption from this accident to first washing the urethra; he also washed it out before and after urethrotomy. Nor did any of his patients any more have chills or fever. Dr. Gerster then presented a urethrotome which he had devised, and used with satisfaction. It had the special advantage of being readily rendered thoroughly clean.



The Finished Litholapaxy Evacuator.

Safe Operation.—Dr. L. Bolton Bangs wished to say that he regarded internal urethrotomy as a perfectly safe operation when performed with the Otis urethrotome. He was not willing to lay so much stress on the danger of too deep incision, nor was there any great liability to dangerous hemorrhage; he spoke of the importance of washing the urethra before the operation, which was also the practice of Dr. Otis and Dr. Brewer. The operation was done by some gentlemen in their offices and at their clinics, the patients being sent away to their homes. This was not safe, and he predicted that such a practice would be likely some time to result disastrously, much to the regret of the operator. He had recently seen in consultation a gentleman operated upon by a man of experience, the operation being followed by extravasation, septicæmia, and death. Probably some simple but important precautions had been overlooked. As to the best time for the first passage of the sound after the operation, he would say in general twenty-four hours. The after-treatment was important; the urethra should be rendered aseptic before and after the passage of the sound, and in some cases after urination.

Dr. Eugene Fuller thought it well, when one first saw a case, to pass a sound several times; if the stricture re-contracted it was then time to cut, and cut thoroughly, dividing all stricture bands. He passed a sound the day after the operation. It need not be passed again for two or three days. It should not enter the deep urethra.

Dr. G. E. Hopkins thought there were many cases, especially moderate strictures in old men, in which divulsion was preferable to internal urethrotomy.

Dilatation First.—Dr. J. D. Bryant said he practised both division and dilatation. He did not believe that in every case of stricture which one saw division was proper. He always first employed dilatation, but if it failed to cure the gleet or relieve the symptoms, or if the patient wished division, he used the cutting instrument. Regarding the danger of incision, he had been amused in listening to the remarks of those who claimed that it was a perfectly safe operation, especially those who devoted so much time to dividing strictures. While they claimed that it was a safe operation they did not end their remarks without cautioning those who might employ it of the dangers which might arise. In his experience he had had severe hemorrhage twice. In one the division was on the floor of the urethra, was made carefully, and, in fact, not sufficiently deep rather than too deep, as subsequently it had to be operated upon again. In the other it was on the roof of the penis. He believed in internal urethrotomy, but he did not believe in the indiscriminate use of it.

Drs. Alexander, Sturgis and Otis made some further remarks, when the discussion was closed by the author. Dr. Otis added that pressure, to control hemorrhage, should not be made at the meatus, but as near the seat of division as possible. Dr. Brewer had found the relationship between the circumference of the penis and of the urethra, given by Dr. Otis, to hold good; for practical purposes the urethra was larger rather than smaller than the estimated size.

Dr. George G. Hopkins, of Brooklyn, presented "A Curette for the Male Bladder." The curette passed through a hollow shaft, and its projection and angle of curvature, as well as the direction of the curvature, whether forward, backward, or laterally, were controlled by a screw at the proximal end. It had been of specia service in a case of papilloma at the trigone, which inter-

fered with urination, which case had suggested its construction.

Dr. F. N. Otis then presented and demonstrated the working of "The Finished Litholapaxy Evacuator," it being the same instrument which he presented as the perfected litholapaxy evacuator at the meeting of the American Association of Genito-Urinary Surgeons, two years ago, with the improvement now, in the fittings, of substituting a screw for cement connection between the bulb and the receiver. This rendered the instrument durable, easily taken apart and put together, much more easily cleansed, and further, it possessed advantages over the Thompson and Bigelow instruments in the direction of lightness, convenience of working, certainty of retention of fragments, etc.

SECTION IN OBSTETRICS AND GYNECOLOGY.

Stated Meeting, December 26, 1889.

J. E. Janvrin, M.D., Chairman.

Hysterorrhaphy: a New Method.—Dr. A. P. Dudley related the history of a case in which he repaired a lacerated cervix and perinæum, and sought to overcome retroflexion by mechanical means, but in the latter effort he was unsuccessful, and was finally led to do laparotomy. Certain important objections, however, led him to hesitate to do hysterorrhaphy in any of the ways in which it had been performed, especially by uniting the fundus with the abdominal walls. In two cases of his own the latter method had resulted in an intractable fistula in the line of the silk ligatures employed, finally necessitating a second laparotomy.

On opening the abdomen he broke up the adhesions about the tubes and ovaries, found the tubes pervious, and, after tapping a cyst in each ovary the size of a thimble, determined to leave them. The uterus was soft, flabby, the round ligaments unusually long, perhaps eight inches. He shortened these in a way to retain the uterus just a little anterior to the perpendicular by first dissecting the peritoneum from the anterior face of the uterus down to within three-quarters of an inch of the anterior ligament, then freshened the proximal ends of the round ligaments, deflected them down upon the anterior wall of the uterus as far as the peritoneum had been dissected off, and fastened them by catgut sutures, about fifteen in number, inserted less than a quarter of an inch apart. The sutures were not continued high enough to interfere with the tubal connections. In their new position the insertion of the round ligaments was about the junction of the lower with the middle third of the uterus. The patient was now convalescent, the uterus was still in the position placed during the operation, no pessary had been worn; the after-result would be reported in the future.

He believed the advantages of this method to be the building up and strengthening of the anterior surface of the straightened uterus, and the fact that the organ, not being fastened to the abdominal walls as in one form of hysterorrhaphy, remained free in the pelvic cavity as in the normal state. As far as he knew, the operation was original.

Dr. A. F. Currier thought there would be likelihood of the adhesions tearing loose, especially in pregnancy. Besides, the operation substituted an abnormal for the natural position. He thought Dr. Wylie's operation of shortening the round ligaments within the abdomen more in accord with nature. By it the ligaments could be shortened any amount, while under Dr. Dudley's method the shortening had to be limited to the distance between the fundus and vesical cul de-sac. Dr. Wylie's operation was simpler.

Dr. E. H. Grandin thought the operation novel, but he believed the ligaments would stretch as they had done under Alexander's operation, the method by which the fundus was fastened to the abdominal walls, etc.

Dr. G. M. Edebohls regarded the operation as a modification of Alexander's, as all operations were which shortened the round ligament, but here it was internal, not external. The past year he had done hysterorrhaphy five times, so far with good results. The details of the operation were important. He passed three sutures through the entire thickness of the abdominal walls, down into the uterus, about an eighth of an inch, out again about an inch from the point of entrance into this organ, then out through the entire thickness of the abdominal walls, the sutures being about a quarter of an inch apart. They were taken out about the tenth day.

Dr. Buckmaster believed such operations were rarely called for, but when required it seemed to him this one had no advantage over Dr. Wylie's method. It left, however, no stiff band to favor intestinal obstruction.

The Chairman thought retroflexion might take place above the point where the round ligaments were finally attached in Dr. Dudley's operation.

Dr. Dudley did not think retroflexion was likely to take place above, for the thickening from exudation and attachment of the ligaments had rendered the uterus stronger. He also replied to some of the other criticisms.

Extra-uterine Pregnancy and Electricity.—Dr. A. Brothers read a paper, entitled "Subsequent Behavior of Cases of Extra-uterine Pregnancy treated by Electricity." In the *American Journal of Obstetrics*, of last year, the author reported a case of extra-uterine pregnancy successfully treated by electricity, and prepared a *résumé* of forty-three cases which he had been able to find in the various medical journals. Since then he had found ten more cases, which he briefly reported. 1. Case of Dr. W. H. Taylor, three months' fœtus, six applications of galvanism; tumor diminished in size. 2. Dr. H. F. Walker, two months' (?) tubal pregnancy, five applications of faradism; cured. 3. Dr. Kalabin, tubal pregnancy of two months, one electro-puncture and thirty-one vaginal electrizations; tumor disappeared. 4. Dr. Kletsch, fœtus eight weeks old, three faradic applications; cured. 5. Dr. A. H. Buckmaster, seen by Dr. Skene, four months' growth, six applications of galvanism; mass reduced in size. 6. Matthews Duncan and Stevenson, faradism first applied to five months' fœtus, then galvano-puncture; woman died a few days later. 7. Boulton and Stevenson, two months' tubal pregnancy, treated by electro-puncture; woman died. 8. Benton, fœtus of eight weeks, ten to fourteen applications of faradism; diminution in size of tumor. 9. Bierwith, four to six weeks' growth, complicating typhoid fever, eight faradic applications; reduced to small nodule after a month. 10. Edebohls, eight weeks' growth, six applications of the interrupted current; complete absorption within six months.

The immediate effects of using electricity in the vast majority of the reported cases had been an abatement of symptoms due to the growth, and a marked diminution in its size. In three cases the fœtus was probably expelled into the uterine cavity. In four, alarming symptoms supervened, but passed away. In two, suppuration with discharge of the fœtus occurred, but the patients made a good recovery. Death occurred in five cases, but only one death could be properly attributed to the use of the electricity. In this case hemorrhage occurred from the sac-wall (Janvrin's case). In the other four cases electro-puncture was the method employed in two; in the third, simple puncture of the cyst after electricity had been discarded was responsible for the fatal result; in the fourth the fœtus was finally killed by morphine injections, and later the abdominal cavity was opened (Wylie).

In order to more accurately determine the subsequent behavior of cases reported cured under the electrical treatment, the author opened correspondence with the gentlemen who had used this method themselves, or knew cases in which it had been used. He requested an answer to the following questions: 1. What secondary dangers has your patient undergone as a result of the treatment?

2. What is the present degree of health of your patient, or when last seen?

Of the fifty cases of extra-uterine pregnancy treated by electricity contained in his tabulated list, he had not traced the further progress of the last eleven, most of which were reported during the last year, for the reason that he was interested in the subsequent histories of those cases which had been treated at least several years previously. He would state, however, that three ended fatally—two after electro-puncture; and in the third morphine followed by laparotomy was resorted to. The other eight were reported cured at the time. The cases treated by electro-puncture, the two fatal cases of Hicks and Janvrin, the three cases in which under electricity the fœtus was expelled through the natural passages, and the two cases in which it was discharged through openings in the vaginal roof, were omitted. This left six cases (reported cured) whose subsequent histories he was unable to trace. The following list showed the behavior of twenty-five cases observed for periods ranging between one and eight years after the employment of electricity:

Case.	Last seen.	Health.	Secondary dangers.	Local condition.
Allen	3 years later.	Good.	None	Tumor left, size fist.
Landis	4 " "	"	Recurrence of extra-uterine pregnancy 4 years later.	Reported cured.
Reeve	1 year later.	"	None	Small tumor left.
Harrison *	1 " "	"	"	" " "
Lusk	2 years later.	"	"	" " "
Billington	8 " "	"	"	Not stated.
Emmet	5 " "	"	"	Small tumor left.
Garrigues	8 " "	"	"	Nothing left.
Herrick	7 " "	"	"	Not stated.
Westcott	7 " "	"	"	Nothing left.
Sims	5 " "	"	"	Not stated.
Cushier	5 " "	"	Recurrence of extra-uterine pregnancy 3 years later.	Nothing left.
Cocks	2 " "	Fair.	None	Slight thickening left.
Lambert	2 " "	Good.	Symptoms of abscess for a time.	Nothing left.
Mundé	2 " "	"	None	Small tumor left.
Berlin	4 " "	"	"	Not stated.
Briggs	4 " "	"	"	" "
Stoddard	3 " "	"	"	Nothing left.
Goelet	2 " "	"	"	" "
Aveling	3 " "	"	"	" "
Gardiner	3 " "	Fair.	"	Not stated.
Mann *	1 year later.	Good.	"	Nothing left.
Brothers	3 years later.	"	"	" "

* Two cases.

Thus it could be positively stated that twenty-five patients (reported cured) had been heard from after the lapse of from one to eight years, and that, when last seen, all were reported well. Many of them still carried traces of the old trouble, and while it would not be fair to assert that these little masses could not in the course of time become troublesome, still the fact remained that, as far as he had been able to discover, they had up to the present caused no inconvenience. Whether electricity was to hold its place in the treatment of extra-uterine pregnancy or not would depend on the stand taken by the American profession, for in Europe it had hardly received the barest recognition. From a careful study of the facts presented in the paper, the author drew the following conclusions in regard to the use of electricity in extra-uterine pregnancy:

1. The risk of rupturing the sac of an extra-uterine pregnancy and causing death by internal hemorrhage is slight. In but one case has this possibly occurred (Janvrin), but the reporter himself thought that the danger existed prior to the employment of electricity.

2. Suppuration of the dead fœtal mass has not occurred in any case in which electricity was employed before the third month.

3. Beyond the third or, possibly, fourth month electricity should not be resorted to.

4. Electro-puncture is to be condemned in all cases.

5. In cases of mistaken diagnosis no harm is done by the electrical treatment.

6. Under galvanism or faradism early extra-uterine pregnancies can be checked in their growth, and caused to disappear entirely or to become shrivelled up. These remaining masses have, thus far, caused no subsequent trouble.

Dr. Edebohls had had two cases of extra-uterine pregnancy treated by electricity. In one he was not able to follow the result after the fourth week, when the symptoms had subsided and the patient considered herself well. The diagnosis in the other case was beyond peradventure, and had been confirmed by Dr. Thomas and Dr. Gillette. It had been reported in Dr. Brothers' paper; no tumor nor symptoms now remained. In the future he would have no hesitation as to what to do in cases of extra-uterine pregnancy which had not advanced beyond the tenth week. He would use electricity.

Electricity Versus Laparotomy.—Dr. Grandin agreed most emphatically with the conclusions drawn by the author. He considered the paper as one of the most valuable which had appeared for a long while. We were now passing through a stage when the question was being widely agitated, Should we do laparotomy in cases in which extra-uterine pregnancy was suspected? The advocates of primary laparotomy contended that electricity would not kill the ovum; that if it should, the woman would for her future life be subjected to every imaginable risk. In this paper we had for the first time a careful collation of facts regarding the results of electricity. These twenty-five cases furnished a more brilliant record than that of primary laparotomy. He need only refer to the cases in this city in which laparotomy had been performed for extra-uterine pregnancy, with the result of two miscarriages, one death, and another bad result the nature of which he could not then recall. We ought, then, to be proud of what had with scorn been termed "the American treatment of extra-uterine pregnancy." Up to the third month he had always contended, and had put his belief into practice in two instances, that electricity would kill the ovum, and that the dead ovum ought not to give rise to trouble. What was the ovum at the third month? A little thing about the size of a hen's egg, the contained embryo about two-thirds of an inch in length, bone not present. He had seen the tube contain as much pus in cases of pyosalpinx without having ruptured. Every intelligent man must grant that this ovum could be killed by electricity; why could it not be absorbed, or pass out through the uterus? He had not the slightest doubt that it could. He believed that many of those who favored primary laparotomy did so for the reason that their work lay more in that direction than in the other. He need only refer to a meeting recently held in a neighboring city (Philadelphia) at which electricity was condemned and primary laparotomy upheld. And on what ground? Chiefly that electricity could not kill the ovum; that it did not kill it; that the cases which had been reported as cases of extra-uterine pregnancy treated by electricity were cases of erroneous diagnosis, and that therefore primary laparotomy should be resorted to and the woman's safety be not trusted to electricity: it seemed beyond belief that anyone could question the diagnosis in all these cases. They were seen by expert diagnosticians, there were all the symptoms of extra-uterine pregnancy, they were treated by electricity, those symptoms disappeared, the tumor shrank or was absorbed entirely, the patients recovered. He concluded by saying that, if the ovum had not passed the third month, and the cyst had not ruptured, he would use electricity.

Dr. A. F. Currier did not yet feel absolutely positive that we must all use electricity in these cases. The results given in the paper spoke very favorably for that method, yet there was some question regarding diagnosis, and, necessarily, must be; it was not impossible that some trouble might yet arise from the remains of the tumor, where present. While his own experience had been limited to only one case, and in that one the laparotomy resulted in death, yet, if he felt sufficiently positive of the diagnosis, he would not hesitate in the future to recommend treatment by laparotomy.

No Question of Diagnosis.—Dr. Macmaster thought there could be no question of the diagnosis in most of

these cases. But one of two conclusions could follow, namely, that they were cured by the application of electricity, or that extra-uterine pregnancy was a harmless matter. He believed it was much less dangerous than was commonly supposed, in many instances, yet he thought the evidence of these histories showed that the ovum was frequently destroyed by electricity. He did not believe we were justified in doing laparotomy before the third month.

Dr. Malcolm McLean said one of his cases appeared in Dr. Brothers' list. In another case, not mentioned in the paper, the ovum was killed by galvanism, and now, at the end of fourteen months, no tumor remained. He would ask the gentlemen who doubted the diagnosis in these cases whether there was an authenticated instance in which electricity before the fourth month had failed, the subsequent course of the case showing it to have been one of extra-uterine pregnancy? He had never heard of one. It had not been shown that the treatment had failed in any instance when properly applied. It was not claimed to be applicable at the fifth, sixth, and seventh months, and cases treated at that time by electricity should be excluded. He was not prepared, however, to say that it should not be used to kill the fœtus after the third month, and, as soon as an attempt at absorption showed itself, do laparotomy to remove the remains.

Primary Laparotomy.—The Chairman explained the position which he had taken the past four or five years with regard to primary laparotomy. His views were founded on experience in one case in which galvanism was employed after symptoms of rupture of some of the small vessels on the surface of the sac, the fœtus being nine weeks old. The day after the fourth application the patient died, suddenly, of rupture of the sac. While he did not attribute the rupture to the use of electricity, yet he then took the ground, which he still held, that where rupture of the sac was imminent, as indicated by sudden, severe colicky pains, etc., electricity should not be employed, but laparotomy should be done at once. Where rupture was not imminent he would not oppose electricity, and had used it himself. Here galvanism should certainly be preferred to laparotomy, by those inexperienced with laparotomy. He did not question the diagnosis in most of the reported cases. Dr. Mann had reported two, not in his own practice, in which extra-uterine pregnancy treated by electricity had been followed by abscess and serious trouble, the patients, however, finally recovering without an operation.

Dr. Brothers closed the discussion. He said Dr. Mann had not mentioned those two cases in his letter to him, but that might be accounted for by their not being cases in his own practice.

Correspondence.

THE THIEF WITH THE BOGUS CHECK.

To the Editor of the Medical Record.

Sir: If you deem that the publication of the following facts in your next issue will be in time to serve as a warning you may use them as you see fit.

Last Friday, January 17th, at 11 A.M., a man about five feet four inches in height, thin face, forty years of age, somewhat bald, wearing a blue overcoat, called at my office in my absence with an alleged check for $35 on the Commercial Bank, and professed a desire to pay a bill of $20 for his brother, a Mr. Purdy, and to obtain $15 in change. As my wife had been victimized by a similar dodge, to the amount of $5, a few years ago, she began to look for the name given in my ledger. During the search the man hastily left. One of my domestics prepared herself and went in the direction he had taken, and met him coming down the stoop of a neighboring physician, when he took to his heels and rapidly disappeared.

As the present is a time when physicians and their families are pleased to collect bills, and, as I believe, most of them stand in need of whatever they do collect, I am moved to state the above, hoping that, if there be any whom this individual has not as yet favored with a call, they may be timely warned against his seductive methods.

Respectfully,

N. S. Roberts, M.D.

New York.

BROMINE IN THE TREATMENT OF DIPHTHERIA.

To the Editor of the Medical Record.

Sir: In the Medical Record, January 18, 1890, p. 64, under "Treatment for Diphtheria," Dr. H. L. Manchester, of Pawlet, Vt., writes of bromine in the treatment of diphtheria. He says he "has never seen any reference to the use of bromine as a disinfectant in the treatment of diphtheria." I would say Dr. Manchester would, by referring back to 1878–79, in the local papers and articles written by Vermont doctors, find that Dr. Middleton Goldsmith, of Rutland, wrote of bromine to be used in the same way as Dr. Manchester speaks of, "in a shallow dish on a high shelf," or by saturating a sponge or cloths and suspending them in the room, he basing his views on the action of bromine on hospital gangrene—a subject which Dr. Goldsmith wrote an essay on, based on his experience in the army, I believe. I treated at least two hundred cases in the towns of Winhall and Jamaica, Vt., in the winter of 1878 and spring of 1879, and I found, in consultation, that other doctors were using it as a disinfectant. If my memory serves me rightly, Dr. S. S. Clemmens, of Manchester, was the first one to call my attention to Dr. Goldsmith's views. I had previously sent to Dr. Chamberlin, Secretary of the Connecticut State Board of Health, for some pamphlets issued by said Board, and, by mistake (as claimed later on), bromochloralum was advised; but after reading Dr. Goldsmith's article, I ever afterward used bromine; and at a meeting of the Patrons of Husbandry, or the Grange, I read an article on prevention of diphtheria, giving the views of different authors, and closed by advising them to get bromine and use according to the published article of Dr. Goldsmith, which the local papers had published. I write this simply to give the credit of prior use by Dr. Goldsmith (and myself, at least), and to assure Dr. Manchester that in 1878–79 I verified its use in practice.

A. D. Ayer, M.D.

Madison, Conn., January 21, 1890.

REFLEX NEUROSIS—A REPLY TO DR. J. H. WOODWARD.

To the Editor of the Medical Record.

Sir: I regret that I was unable to state my view of the relation between peripheral irritation and nervous phenomena with sufficient clearness to be understood by Dr. Woodward. Lest others of your readers may be in the same state of perplexity, will you kindly allow me to restate my position. It is this: Peripheral irritation sometimes—in my experience rarely—produces nervous symptoms. These nervous symptoms taken together constitute a class of affection which is called a reflex neurosis, of which class there are spasmodic, convulsive, painful, and other varieties. Each of these varieties of reflex neurosis resembles, in some particulars, a certain nervous disease, but can be distinguished from that disease when carefully examined. To be more specific, a reflex convulsive neurosis may resemble epilepsy; but true epilepsy develops in a person of neurotic constitution, with a bad heredity, frequently after a sudden mental shock, in the form of a convulsive seizure of some kind, which seizure repeats itself after an interval of several months, and again after a shorter time, until finally the attacks may reach the frequency of one in a month, or even in two weeks, being usually attended by complete loss of consciousness during the seizure and by entire subsequent

lack of knowledge of what has occurred. In a reflex convulsive neurosis the family history of epilepsy is often wanting, the seizures recur with great frequency from the outset, from two or three daily (as in the convulsions of teething) to sixty daily (as in the case related), being not usually attended by a complete loss of consciousness, since even during the attack the attention of the patient may be aroused. I cannot make a more concise statement regarding the differences between true chorea and a reflex spasmodic neurosis than that already quoted by Dr. Woodward. Looking at the seizure alone, or at the spasm alone, I do not think it safe, in the majority of cases, to make a diagnosis. Looking at all the facts obtained by eliciting a complete history, and then by making a thorough examination, I think a differential diagnosis is usually perfectly possible. There are always some cases, however, in which it must be preceded by an observation of the patient for a short period of time. Whether during that time the treatment prescribed hastily on a careless diagnosis will be better than that pursued tentatively on the most probable hypothesis I leave Dr. Woodward to judge. As I have never seen any permanent harm come from the medicinal use of arsenic in chorea, and am in this position supported by the statement of Dr. Seguin, whose wider experience adds much to its force, I should not hesitate to use it as an aid to diagnosis if necessary. It would certainly be more harmless than cutting the ocular muscles as an experiment to detect a "latent" "phoria." I hope that these statements are sufficiently clear.

Permit me, in closing, to say that the object of my paper was less to draw sharp diagnostic lines than to show that peripheral irritation is not a frequent nor an adequate cause of nervous disease, and that it is never a cause of true chorea or epilepsy. Yours, very truly,

M. Allen Starr, M.D.

January 21, 1890.

THE ALLEGED CHLOROFORM MURDER—REPORT OF AUTOPSY ON MRS. KNIFFIN.

To the Editor of the Medical Record.

Sir: Our city has been greatly excited over the murder of a Mrs. Myra Kniffin by the use of chloroform. I thought it might be of interest to the readers of the Medical Record to have a report of the post-mortem examination. If it is of any value it is at your disposal:

Autopsy: January 4, 1890, 3 P.M. Examination made by Drs. Leavitt and Struble, assisted by myself.

Body that of a female, thirty-three years of age; eyes hazel; eyelids closed; hair light brown; pupils slightly dilated; *rigor mortis* well marked; lips of a pinkish color, the lower one shows the impress of the incisor teeth; her appearance is not that of death but of healthy sleep, so rarely seen under such circumstances; around the mouth is a circle of excoriation as if some irritant had been applied; on the chin of the right side are four finger scratches, with the cuticle torn upward and outward; this can well be seen on three, on the fourth it is torn away; they are so closely clustered together that the hand inflicting them must have been small. There are no other marks of violence, some discoloration due to suggillation found on the back.

On opening the cranium the membranes of the brain are found healthy; no congestion, the blood being of a brighter hue than usual; the blood unusually fluid; there is the normal amount of serous fluid, the brain and appendages are normal.

On opening the chest there are found firm pleuritic adhesion of both lungs to the chest-walls, those on the left side most marked; the apex of the right lung shows commencing tubercular degeneration. Lungs are moderately congested, marked hypostatic congestion in the lower part of both, back. Heart small; right ventricle dilated and flabby, left normal; fatty infiltration; valves are normal—fit well; heart empty; no clots or blood in either ventricle.

The trachea shows marked signs of irritation, extending from the vocal cords downward; a beautiful pink punctation is seen in patches, most marked when the membrane is slightly loose and raised. Considerable frothy mucus at lower part, and of a slight pinkish color in the bronchia; air-vesicles contain a slight amount of frothy mucus.

On opening abdomen: Liver congested; bladder empty; spleen normal; kidneys healthy; stomach taken out and sent to an expert for examination of contents; no smell of any kind to be detected except that which is usual in such examinations.

The conclusions to be arrived at are that death must have come on suddenly, and a short time after forced inhalation, and that there was a paralysis of the heart; the absence of blood in the right side may be accounted for in the unusual fluidity of the blood, which permitted its escape while removing the lungs and heart from the chest, although the greatest care was taken to avoid this accident.

One of the questions asked on the inquest was whether a person could be chloroformed while sleeping, as seems to be the fact with this person. I think the cases cited in the different works on this subject do not have any bearing upon those of this kind. Where the experiment has been tried it has always been done by experts in the line of safety, with chloroform diluted with air; but when a criminal goes to work the conditions are altered, he is indifferent as to results, he uses the liquid in full concentration and forces its inhalation; the struggle must be brief, if any, as death is certain under such circumstances to all animal life if continued for any length of time. In regard to the scratches found upon the chin, I am inclined to think they were done by the murderer, as he must have held the soaked cloth over the mouth, and on the victim moving her head accidentally inflicted them. That they were self-inflicted I doubt, as to pull the cuticle upward and outward would require an awkward and unnatural movement of the person's own arm and hand.

H. Waldburg Coleman, M.D.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from January 19 to January 25, 1890.

Loring, Leonard Y., Major and Surgeon. By direction of the President, the Army Retiring Board appointed by War Department order, dated January 8, 1890, from Headquarters of the Army, to meet at Los Angeles, Cal., will meet for his examination at San Diego, Cal. S. O. 18, A. G. O., January 22, 1890.

Spencer, William G., Captain and Assistant Surgeon, Fort Bridger, Wyo., is hereby granted leave of absence for one month. Par. 1, S. O. 4, Department of the Platte, January 20, 1890.

Black, Charles S., Captain and Assistant Surgeon. By direction of the Secretary of War, the extension of leave of absence granted him in S. O. 1, January 1, 1890, Department of the Platte, is further extended to include April 30, 1890.

Black, Charles S., Captain and Assistant Surgeon. His resignation has been accepted by the President, to take effect April 30, 1890. Par. 1, S. O. 18, A. G. O., January 22, 1890.

Official List of Changes in the Medical Corps of the United States Navy for the week ending January 25, 1890.

Berryhill, T. A., Assistant Surgeon. Ordered to examination preliminary to promotion.

Wentworth, A. R., Assistant Surgeon. Ordered to examination preliminary to promotion.

Medical Items.

Contagious Diseases.—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending January 25, 1890.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	17	5
Scarlet fever	57	10
Cerebro-spinal meningitis	2	1

Diphtheria	92	21
Small-pox	0	0
Varicella	4	0
Cholera	0	0

The Late Dr. Lewis H. Sayre.—At a meeting of the New York Pathological Society, held January 22, 1890, the following minute was adopted: "The New York Pathological Society has heard with sorrow of the death of one of its most efficient members, Dr. Lewis Hall Sayre, which occurred during the night of January 2, 1890. Dr. Sayre was the son of one of the honored founders of this Society, and was himself an active and valued member, having been a frequent attendant at its meetings and having served faithfully during the year just passed on one of the most important committees. While respected by all for his scientific attainments, he could count among the members of the Society not a few warm personal friends whom his many excellent qualities of mind and heart had drawn around him. Lewis Hall Sayre was a skilful and a conscientious surgeon, a cultured and a kindly gentleman. The members of the Pathological Society, while extending to the bereaved father and to the family of their departed associate their most heartfelt sympathy, desire also to spread upon the minutes of the Society an expression of their own sorrow at the loss which they have sustained. (Signed) J. West Roosevelt, Thomas L. Stedman, Committee."

Explosion in a Dentist's Office.—A patient was suffering quietly in a dentist's chair, one mild January afternoon, in Canton, O., when he was suddenly expelled, the operator and several of his household effects accompanying him. After quiet had been restored it was found that a vulcanizer had exploded with great force, tearing a large hole in the wall and making a wreck of the dentist's office.

Pathogenesis of the Microbes Contained in Malignant Tumors.—Dr. Verneuil has directed attention to the fact that the tissues, which are the seat of malignant neoplasms (cancers, sarcomas, epitheliomas, etc.), may, at a given moment, be invaded by divers microbes, the origin, species, and nature of which it has, so far, been impossible to determine (*The Provincial Medical Journal*). This invasion, the causes and mechanism of which are alike unknown, may remain latent for an indefinite period, but in certain cases, in the evolution and nutrition of the tumor, it may lead to several modifications, such as the rapid enlargement, the softening, or the ulceration of the part affected. Microbes are not to be found in all neoplasms, or even in all neoplasms of the same kind, nor yet in every portion of the neoplasm invaded. They are not to be found, for instance, in lipomas or in pure fibromas; they cannot be found in the early stages of sarcoma or cancer, in which the progress is slow and the growth is covered by healthy skin; on the other hand, they are nearly always to be found in softened and ulcerated tumors. These microbes, besides their irritant, phlogogenic and pyrogenic action, which they exercise locally even on the diseased tissue, possess other pathogenic properties, which may affect the whole system. Thus, so far as an opinion can be found, they may give rise to a more or less intense and irregular febrile condition, while they are pent up in a tumor about to grow rapidly or to soften. Moreover, during the removal of a tumor, they may impregnate the fluids contained in the softened parts, infect the operative wound, and so inoculate it as to develop septicæmia, which may lead even to death. The knowledge of this last fact pleads strongly in favor of the removal of malignant neoplasms, so desirable from every point of view, and suggests forcibly to surgeons the necessity of adopting preventive measures, both during and after operations, for the extirpation of tumors infected with microbes.

Is Phenacetin a Remedy in Whooping-cough?—Dr. R. Heimann, of Landau, answers the above question affirmatively, having used the drug experimentally in a case in which antipyrin entirely failed. The success was so surprising that he administered the drug in two other cases. It reduced the number of paroxysms, which had been from ten to fifteen per diem, to three, and on some days they entirely ceased, only reappearing at night, when no phenacetin was given. Dr. Heimann gave a boy of three years six grains in four doses of one grain and a half, a girl of two years five grains in three doses, and an infant of seven months three grains in four doses, without observing the slightest ill effects. One grain and a half of phenacetin would, on the average, retain its effect for three hours. The author recommends further trials of the drug.—*The Lancet.*

"Change of Climate is what you need," said the high-priced physician, after he had listened to all the details of the patient's case. "Change of climate!" exclaimed the patient, in surprise. "Why, man alive, I've never had anything else. I've lived right here in New England all my life."

An Exorbitant Fee.—A woman brought her daughter to a friend of mine practising in the "Pottery" district. The girl had dislocated her jaw, which dislocation was soon reduced by the usual method, and a bandage applied to keep it in position. On being asked the fee, my friend, not having had a similar case in private practice, went into another room and consulted a tariff of medical charges published by the Shropshire Ethical Society, and found "for reducing dislocation of jaw, one to three guineas." Seeing that the woman was not in good circumstances, he felt that the minimum fee was not likely to be forthcoming, so he tentatively asked whether the girl had ever had the jaw out before. "Oh, yes, sir," she replied, "about twelve months ago, and was treated by a doctor at ——." "How much did he charge you?" "A shilling, sir." "Didn't that strike you as being a somewhat peculiar fee?" "Well, sir," was the reply, "*we did think it a good deal.*"—*Birmingham Medical Review.*

Politics and Science in Canada.—In referring to the new Protestant Hospital for the Insane in Montreal, and the appointment of a medical superintendent, which has not been made as yet, the *Montreal Medical Journal* says that it is not the custom in that country to appoint men to these positions because from experience and special education they are fitted for the work. In most of the provinces the first, and, in fact, the only qualification, is the reputation of being an energetic machine politician. The credentials of the candidates do not consist of what they know and what they have seen of insanity, but what they have done for their "party." To be a rejected parliamentary candidate is a qualification which rarely fails in securing the desired position.

The Inconvenience of Sweat-bands in Hats.—Sweat-bands of hats may contain even twenty-eight per cent. of fatty acids, which in summer may penetrate into the forehead and cause inflammation, and corrode deeply into the skin. Rub with burnt magnesia every little while, so as to leave a small film on the band; wipe it off with a cloth before applying again.—*Journal of Cutaneous and Genito-urinary Diseases.*

NEPHRO-LITHOTOMY—SOME CASES, WITH REFLECTIONS.[1]

BY E. L. KEYES, M.D.,

NEW YORK.

GENTLEMEN: This calculus which, consisting of seventeen fragments, I place before you, was in the kidney of a middle-aged gentleman about seven weeks ago. The gentleman is now well, as far as the operation is concerned, except for the remaining fistula, and possessed of both kidneys. The stone is mine, by right of discovery and possession. The history shall be yours presently. The stone is a single, large, branched, phosphatic calculus. Each of the seventeen segments shows a point of fracture where it was separated from the parent stem. The weight of the fragments is two ounces, and the case is a very interesting one, and so strikingly illustrative of the brilliant possibilities of the modern operation, nephro-lithotomy, that I have determined to make it a text, and, collecting my other cases in the same line, to give you such reflections as have occurred to me from my personal experience, in an operative way, with cases of stone in the kidney, actual or suspected, six in number. All of these recovered promptly from the operation, which—the operation—I have come to look upon as a much more simple matter than I formerly did; and it is in the hope of encouraging this same opinion in others that I offer you this short paper.

Reproduced (Free-hand Drawing) from the Fragments.

I shall briefly report the cases as they occurred chronologically, with a running commentary upon each, summing up with a few conclusions. In one of the six cases (Case II.) an abscess without stone was discovered in the kidney. In another (Case IV.) no stone was found, after very thorough exploration.

CASE I.—In October, 1878, X——, who had been treated all summer by a medical gentleman for what was called ague, was found to have an enlarged right kidney, displaced downward. This I aspirated posteriorly. The pus disappeared from the urine, and the patient improved immensely; but very soon the symptoms and tumor reappeared. A second tapping, two weeks later, relieved less, and it shortly became evident that pus was now outside the capsule of the kidney. I therefore cut him in the loin by a vertical incision, and evacuated a large amount of pus. I opened the kidney, found it pretty well disorganized, and with the finger removed a few very small phosphatic concretions from the pelvis. The operation had been delayed too long. There were many complications, and recovery was protracted, so that it was not until several months later that the patient walked to my office. The fistula never healed entirely.

Remarks.—This case is a poor one in every sense. In the first place, it was not strictly a case of stone in the kidney and nephro-lithotomy, but rather of pyelo-nephritis with disorganized kidney, relieved by nephrotomy, the small phosphatic concretions being accidentally found, not operated for, when the incision was made. The quantity of pus was very considerable, the concretions quite small.

Yet little apology need be made in this case, since it occurred in 1878, and nephro-lithotomy was then not even a name. H. Morris's first successful case of deliberate nephro-lithotomy was performed in 1880.[1] Of course, stony matter had been removed from abscesses in and around the kidney before this date, and the possibility of removing stone from the kidney by operation had been mooted from time to time since the days of Hippocrates, and perhaps performed, as in the celebrated case of Hobson, alleged to have been cut by Marchetti, of Padua.[2] On this case of Marchetti's, upon which Morris throws doubts, and six others in which the operation of nephro-lithotomy had been planned but failed, Morris[3] comments, in claiming originality for his first case, in 1880.

Annandale,[4] long before this, had dilated a fistula leading into the pelvis of the kidney, and successfully removed a stone of seventy-two grains.

George W. Callender,[5] in 1873, operated upon a woman successfully in St. Bartholomew's Hospital, cutting through the capsule of the kidney into an abscess, and removing a stone with the pus.

Peterson[6] published a case of "pyo-nephrosis calculosa," April 5, 1880, before Morris's papers appeared; the patient, a female, aged thirty-nine, having been successfully operated upon. The method was puncture, aspiration, laminaria tents, lithotrite, forceps; yet all these cases, like mine, are those in which the operative undertaking was really a nephrotomy, and although the pus was within the capsule of the kidney, and although this capsule was opened, yet the stone was an accidental discovery, and the surgeon's motive for operation was to evacuate pus.

In 1869 Thomas Smith had read a paper before the Medico-Chirurgical Society of London, suggesting a method of removing stone from the kidney, and in 1878 Thornton tried it, but found only pus; so that the credit of

formally diagnosing kidney calculus beforehand, making a plan for its removal, and carrying out that plan successfully, belongs certainly to Henry Morris—the year being 1880. Since that time, in the past ten years, what splendid advances have been made! My successful case, therefore, of nephro-lithotomy, in 1878, does not count, because perhaps a pint of pus was evacuated, and only a few grains of accidental stone, the existence of which was not suspected when the operation was undertaken. In my second case—which was one of formal nephrotomy, the kidney being movable, its capsule not adherent, and all the pus being within the kidney—it is also hardly fair to speak of nephro-lithotomy, because here, too, the pus (and there was more than a pint of it) was the substance sought for, and although there was a possibility of stone, none was found.

Case II. is a gentleman, aged forty-one, with all the evidences of tubercular pyelo-nephrosis, a globular movable kidney in his flank, no peri-nephritic adhesion or inflammation. This was all the case. I cut down upon the kidney by vertical incision, in the presence of Dr. Van Buren, September 25, 1880, clearly exposed the kidney, and opened its capsule into a large abscess with the Paquelin red hot knife. No stone was found in the abscess. Prompt recovery followed, and the patient lived several years with a small fistula in his side. The other kidney and both testes were tubercular.

Case III., I may call my first of deliberate nephro-lithotomy; yet this is also an imperfect case, strictly speaking, for the patient was an oldish man (sixty-two years of age) with already a small fistula in his back, left after an operation for an alleged diseased rib. I cut down upon and into this kidney, and removed in fragments about a drachm of uric-acid stone. This was in the year 1887. Prompt recovery from the operation followed, the urinary symptoms improved, but the original fistula persisted and another proposed, more extensive, operation for its relief was denied.

Case IV.—My next case is very curious in this, that the patient—then aged fifty-one—had been formerly sent to me from a neighboring State, with hæmaturia, to be treated for kidney disease, since the doctor had examined his bladder and found nothing. I discovered a small stone in the bladder, removed it at once by litholapaxy, and sent the patient home on the fourth day, well as to his hæmaturia, but with a diagnosis of a remaining calculous pyelo-nephritis.

Some years later, in February, 1888, this gentleman was sent back to me again with hæmaturia of nine months' standing, and a statement to him by his physicians at home that they had this time touched stone in the bladder. I explored the bladder, but found nothing. Then, after some study, I believed that I could locate the seat of the hemorrhage in the left kidney, on account of subjective pain, pain on pressure, previous kidney colic on that side, and pain radiating down that groin into the bladder and testicle, as well as by the certain test of washing the bladder. I therefore, in February, 1888, made an exploratory nephro-lithotomy upon this gentleman. The incision was transverse, just below the rib. The kidney was exposed, stripped of its fatty capsule entirely, so that with the thumb and finger I could pinch laterally the entire kidney from top to bottom, feeling for a stone. I could feel the ureter and the great vessels easily, and count the arterial throb. The kidney was rather small and moderately granular upon the surface. I could detect no soft spot (as of abscess), and no hard lump produced by stone. I pinched the pelvis and felt nothing within; I next, systematically from top to bottom, pierced every portion of the kidney, over each space of about three-fourths of an inch, with a long, sharp acupressure needle. I did not strike stone. I therefore disinfected, drained, and closed the wound. Reaction was moderate. Union by first intention occurred throughout. The patient sat up on the ninth day, went downstairs on the tenth, and home, several hundred miles by rail, on the eleventh, cured as to his pain and hæmaturia; the latter, which had lasted nine months, ceasing a few days after the operation.

This patient's condition remained satisfactory until he died suddenly, whether by the heart or by apoplexy, I could not learn, about a year after the operation.

Remarks.—This gentleman was thin and tall, with plenty of lumbar space, so that the transverse incision was ample to allow manipulation of the kidney. Judging from my experience in removing the kidney by the posterior incision, I may state that in fat, short individuals, a liberating vertical incision downward, along the outer border of the quadratus, would be very desirable, perhaps essential, for the execution of thorough exploration and manipulation of the kidney in search of stone. My belief is, that in this case there was no stone in the kidney, but that the organ was in granular degeneration (the urine always contained casts), and the movements of the kidney caused by the motion of the body in walking about, kept up a sufficient congestion to yield a constant flow of blood. Separating the kidney from its attachments in the operation allowed sufficient inflammatory cohesion in the process of repair to fix it more firmly in place, give it rest, and thus cure the hæmaturia. Certain it is that the pains ceased and the blood no longer appeared in the urine after the wound cicatrized. The ease of the operation and the promptness of recovery are features worthy of note.

Case V.—X——, aged thirty-eight, with a history of intense paroxysmal attacks of left kidney colic on several occasions, without the passage of stone, was referred to me in July, 1889. I found deep, fibrous stricture and considerable cystitis, with great frequency of urination of a purulent fluid. No stone in the bladder. He was very fat. The kidney could not be felt. All the subjective pain was at the end of the penis, and over the symphysis, at which latter point also pressure produced pain.

As the deep urethra was quite narrow, and as he improved considerably in his vesical symptoms under moderate dilatation, I concluded that perineal cystotomy was appropriate, since the stricture proved tough and resilient, both to cure the latter and drain the bladder. This operation was accordingly performed July 31st, by my assistant, Dr. E. Fuller. Prompt recovery from the operation followed, and great improvement in all symptoms, but the idea of trouble in the left kidney was never abandoned because, although casts were absent and the pus diminished, yet some kidney cells were found and the amount of albumin present was disproportionate to the quantity of pus. Yet the patient continued to improve, had no pain in the left side, got up and about, and was doing reasonably well, when suddenly, without obvious cause, at the end of August he was taken down with acute orchitis in the left testicle. This went on to suppuration, and a considerable slough of the substance of the testicle came away from the abscess after it had been incised. After this, improvement again set in and continued for a time; but shortly, more fever and more vesical irritability manifested themselves, and finally a sharp chill, followed by another, and high fever with great prostration, came on, and then intense pain in the left kidney region, and at last a gush of pus, which, however, afforded no relief to the symptoms. The patient's condition was rapidly becoming desperate; the urethra and testicle were well, but it was clear that matters were going badly, and that further surgery was called for. I therefore determined to cut for stone in the kidney.

The usual transverse incision easily found the kidney, high up and deeply covered by its fatty envelope. I exposed the capsule and handled the kidney freely. I detected a softish spot, and introducing a fine exploring aspirating needle, drew out some badly formed urinous pus, and with the needle touched stone. I enlarged the incision, introduced the finger, and found a stone as large as a good sized marble. This I removed with forceps,

drained the cavity after further exploration had failed to detect other calculi, and closed the external wound except for two large rubber drainage-tubes. Recovery was prompt and uneventful. The wound healed entirely, with great rapidity, and the patient has since enjoyed excellent health, his urine being almost clear, and his health and functions satisfactory.

Remarks.—This case is remarkable for its complication of disorders, the obscure symptoms yielded by the stone proper—which indeed never became pronounced until the final suppuration occurred around it—and for the very moderate shock of the final operation, and the brilliant recovery that followed it.

Case VI.—X——, a vigorous gentleman, aged thirty-nine, came to me from a neighboring State for consultation and advice relative to a great frequency of urination, of several months' duration, and the passage of urine which resembled pure pus. It was as thick as gruel, acid in reaction, of high specific gravity. The total quantity passed in the twenty-four hours was ample, and the amount of urea satisfactory. He had formerly had a small stone removed from his bladder by perineal lithotomy, and recently had had severe kidney colic for the first time, and some pain in the left kidney region. I had no difficulty in mapping out a large, tender left kidney, and in view of the amount of pus lost and the rapidly increasing intensity of his symptoms, I urged immediate operation. This he declined, since he desired to return home and arrange his affairs before submitting to the knife. He went home with all his symptoms constantly aggravating, and shortly wrote me that his pains were worse, his fever higher, and finally, that he was passing not only an abundance of pus by the urethra, but also from time to time considerable gas. He returned to New York in December, 1889, in high fever, passing pus and intestinal gas by the urethra. I obtained his permission to open his kidney and remove any stone I discovered, but he would not consent to have his kidney taken out—an operation which I thought might be advisable in consideration of the manifest fact that there had been extra-renal suppuration, and that a communication must exist between (I believed) the transverse colon and the abscess above the kidney.

The operation was a very formidable one. A transverse incision just below the last rib easily opened the way to a hard mass of fibrous, inflammatory deposit, which surrounded the kidney and held it fast. Through this dense, crackling mass of inflammatory deposit I cut for nearly three-fourths of an inch before I came to the true capsule of the kidney. There was no fat whatsoever encountered in this incision. When I reached the kidney it was as firm and hard as stone. There was no suppuration. The true capsule of the kidney was unbroken, but through it I could feel the hard, uneven masses of stone. I incised the capsule freely, and with the finger, supporting the kidney with the other hand placed outside of the abdomen, I gradually worked my way along the sides of the stone, tearing the kidney substance away on either side. The hemorrhage was very great. I soon became convinced that the stone was a large branched one, and concluded that it must be broken up if possible and removed in sections, if I was to get it out at all without taking the kidney with it. The stone proved to be phosphatic, and not being larger at any place than the finger, I was enabled to break it, partly with forceps and partly with the finger, and to remove it piece by piece. In this way I ploughed up the whole of the posterior surface of the kidney, and followed the branches into the calices and the substance of the kidney in all directions. When I had gotten it about all out below, a work requiring no little patience and strength, I attacked the remaining branch at the top of the kidney. In loosening this section I at last broke into an abscess-cavity outside of the top of the kidney. From this escaped thick, bloody, badly smelling pus and a quantity of gas.

After satisfying myself that no stone was left, I irrigated freely and deeply with water, too hot to be borne by the hand, and succeeded in arresting the free hemorrhage, and cleansing the purulent cavity, apparently. This water was so hot that it almost cooked the tissues, causing the edges of the cut muscles at the outer part of the wound to look much like under-done boiled mutton. Four large drainage-tubes were inserted. One passed through the kidney and out into the abscess-cavity above, one terminated in the cavity of the pelvis of the kidney below, and the two others were placed for superficial drainage along those portions of the wound that were to be sutured. At least two and a half inches of the incision about the deep drainage-tubes were left unsutured, and packed lightly with iodoform gauze, as I expected an escape of some of the intestinal contents at this point. Shock was excessive. The temperature ran moderately high, and the pulse was feeble and very rapid for a couple of days. No more gas escaped from the bladder, but it came from the wound freely on the second day. There was also an escape of what appeared to be fecal matter from the wound on several occasions, and similar material once from the bladder.

It is needless to give close details of the recovery that followed, which was practically uninterrupted. At the end of the third week the patient sat up and walked about, and before the end of the fourth week he made an uninterrupted journey on the railway of several hundred miles to his home, the large fistula being of course still open, but the greater part of the wound solidly closed, his urination being normal, and the urine itself generally clear and sparkling, with a trifling deposit of cloudy mucus and trace of pus. The stone weighed two ounces, and is the one I have shown you at the beginning of my remarks.

I have not had an opportunity to look up the literature of the subject, to see how large a stone has been removed successfully from a kidney, but I do not remember to have read of any of these dimensions, and I feel certain that, all things considered, the gravity of this case was very real, and the success a brilliant vindication of the efficacy of nephro-lithotomy. The drainage of the abscess-cavity above the kidney was good, and long continued, and the small perforation which I believe existed between it and the transverse colon must have closed spontaneously.

In a letter received from the patient last week, I learn that the large hole I left for drainage in the back is closing too rapidly, and that now some pus is beginning to show again in the urine. It is quite possible that, if the drainage cannot be maintained effectively in the back, a secondary operation may be advisable to remove the stump of the kidney, but this in no way lessens the positive advantage the patient has derived from his first operation.

Nephro-lithotomy as an operation of the first order is, to-day, an established surgical fact, and needs no words of mine in its justification. The obscurity which often surrounds diagnosis of kidney stone, the fact that fruitless search has often been made for it through a surgical opening, and the possibility of having symptoms in one kidney when the stone is in the other, together with the idea in the minds of some that the operation itself is a formidable one, have often led to hesitation in resorting to the knife; a hesitation which, I think, will gradually disappear as our experience becomes broader. For what better justification of the exploratory incision can there be than the fact (illustrated by my fourth case, and very often at the hands of other operators) that, even when it is negative in its results, as far as finding stone is concerned, yet a cessation of the symptoms, for the relief of which it was undertaken, very frequently follows its employment. Then again, as to the seriousness of the operation viewed simply in a surgical light, I think it is generally over-estimated. I have explored in all, in this particular line, six times, and every case, some of them quite serious ones, has done perfectly well and made prompt recovery, as far as the operation itself was concerned.

I do not know the verdict of pure statistics upon this point. If they have been collected, I have not seen

them. My record is perhaps too good to generalize from, and the same may be said of Knowsley Thornton's [1] published statistics of his personal operations, which were thirteen in number, with one death, from suppression.

Thornton, however, does not believe in the simple posterior incision. His field is abdominal, and his preference, for exploratory purposes and to clinch diagnosis, the anterior incision, Langenbuch's, and a combined operation which he has performed ten times.

He makes a serious point of the difficulties of diagnosis, which we all know to be considerable, and the details of which I have no space here to consider; but his method is (and his success justifies its exposition here) to open the peritoneum through Langenbuch's incision along the outer border of the rectus, explore both kidneys, verify in this way the existence of stone in one kidney and the integrity of the other organ; then, with one hand in the abdominal cavity protecting the colon, keeping the peritoneum out of the way, and firmly steadying the kidney, to cut down through the loin by a small incision directly upon the kidney, at the point where the stone is located, and cutting directly through the kidney substance at this point, to extract the stone with forceps through the posterior opening.

This, as may at once be seen, gets the stone out with the least possible amount of displacement of the kidney from its natural attachments, and extracts it through the smallest possible opening, which is entirely extra-peritoneal, and may be drained and treated antiseptically in the usual way.

Much may be said in favor of this operation for use by those entirely familiar with peritoneal surgery and antiseptic abdominal exploration. For those not at home in this region, an extra element of risk is inflicted upon the patient by opening the peritoneum, and I personally do not think that it is generally either necessary or justifiable; but I believe it to be an admirable resource in irregular cases and those of very uncertain diagnosis.

My conclusions, therefore, based upon what experience I have had, are the following:

Conclusions.—1. The posterior exploratory incision upon a kidney suspected to contain stone is devoid of any serious danger when performed with proper care, and should be resorted to more often than is at this date sanctioned by general surgical opinion.

2. The best incision is the transverse, below the twelfth rib, with as much of a liberating incision downward along the line of the edge of the quadratus as may be required to gain ample room.

3. The kidney may be freely cut into and rudely lacerated with the finger, when the stone calls for it, without producing any hemorrhage which hot irrigation will not control.

4. It is better, in the case of a large branching calculus, to break it up and extract it in fragments, rather than to attempt to remove it entire.

5. So little danger attaches to the posterior incision that it seems wiser always to make it the first step, reserving peritoneal exploration for a later resource in cases where the posterior exploration miscarries.

[1] Park Avenue, January 28, 1890.

A Family Dairy.—Dr. Cremer reports in the *Deutsche Medizinal Zeitung* the case of a woman, twenty-eight years old, who gave birth two years ago to a child, which died soon after. The breasts continued to secrete milk, however, so that even at the present day the woman has enough milk to nourish a child, and is obliged to keep the breasts constantly covered with cloths to prevent soaking her dress. The aunt of this woman had one child in early life, and from that time until her fiftieth year had an abundance of milk, and used to nurse her grandchildren whenever their mother was tired or disinclined to nurse them herself.

A DEVICE FOR FORCING RESPIRATION, WITH A REPORT OF ITS USE IN THREE CASES OF OPIUM NARCOSIS.

By C. R. VANDERBURG, M.D.,

LECTURER ON PATHOLOGY AT STARLING MEDICAL COLLEGE, COLUMBUS, O.

Artificial respiration has been recommended and used for a great number of years in cases where respiration fails or has never been established (as in asphyxiated infants), owing to paralysis of the respiratory centre. This centre is not only affected by an increased amount of carbonic acid in the circulation, as occurs in asphyxia from various causes, but may also be paralyzed by certain drugs when taken into the system, notably opium in its different forms. Paralysis of the respiratory centre is the ultimate result of a surcharging of the blood with carbonic acid, as in drowning or inhaling various gases, or rapidly terminates in it, as in poisoning from drugs which paralyze the centre of respiration. In either case we have respiration failing, while the other bodily functions are partially active. The great, and in most cases only, necessity, if the case is seen in time, is air in the lungs of the patient. These cases need air only for the time being, and if this can be supplied properly a great many can be saved. Every physician has, no doubt, run across these patients many times during his practice. In many of them air should be supplied within two or three minutes, as in drowning; in some, retrograde changes are not so rapid, and it takes several hours for death to take place. It may not be out of place to mention some of the more common poisons in this connection which kill eventually from paralysis of respiration, most of them ending in asphyxia. Various gases, as carbonic oxide, nitrous oxide, marsh gas, natural and coal gases, in fact any gas, even oxygen itself, might be mentioned; vapors, as chloroform and ether; lastly, asphyxia from drowning and opium narcosis. If I pick up a book on poisons and their antidotes I see artificial respiration also recommended for a variety of poisons, such as aconite, belladonna, chloral, conium, hydrocyanic acid, and nux vomica. Quite an array of drugs, it is at once seen, affect respiration, if taken in poisonous doses. In general, we may assert of any of the above that the ultimate result of the poison is an accumulation of carbonic acid in the circulation greater than normal; there is no longer healthy blood. As a consequence there is a partial or total cessation of the secreting and excreting organs, and hence the poisons are retained. The functions of respiration, circulation, and secretion are interfered with, and if these are not soon rectified dissolution rapidly follows.

The methods of supplying this much-needed air have, all will admit, always been very imperfect. The older methods—those of Sylvester, Hall, Howard, and others—depend upon the resiliency and elasticity of the chest-walls, lungs, and diaphragm, they quickly springing back after being displaced. Various movements of the body and limbs are also used to secure the same end—respiration. The amount of air displaced in the lung at each of these movements is necessarily small, and the manipulation is tiresome to all parties taking part in it, as well as detrimental to the patient; but we must admit that, although it is imperfect, it has saved many lives, especially in cases where the effects of the poison are rapidly eliminated. An example of this would be a case of drowning.

There seems to be, up to the present time, a scarcity of means or devices for forcing air into the lungs, a procedure which would naturally suggest itself, particularly for cases which are protracted. The reason for this, I think, is that no one ever dreamed of the possibilities of this method. To Dr. George E. Fell, of Buffalo, belongs the credit of demonstrating to the world the fact that air can be forced into the lungs without any damage to them, and furthermore, as a potent therapeutic agent it excels any discovered for centuries. He has coined the phrase "forced respiration.' Others have at different times used devices for forcing air into the lungs, but they never brought re-

sults which are so overwhelming before the public. Who ever dreamed of saving a patient by forcing air into the lungs for over twenty hours? It reads like Baron Munchausen, but nevertheless it is a fact.

The cases upon which the doctor has had such surprising results were poisoned by that most potent yet dangerous drug, opium, from which many die annually throughout the country, it being given in overdoses by physicians and druggists, or taken with suicidal intent. The method of Dr. Fell consists in the performance of tracheotomy, inserting a tube into the wound, and connecting this with a bellows; a provision is made for air having been inhaled to be exhaled outside of the bellows, so that there is always a change of air. In this manner a respiration can be kept up for hours which much resembles normal breathing. From the use of his method Dr. Fell has reported some remarkable results. Anyone reading the report of his cases cannot help being convinced that those thus treated were saved, and by forced respiration alone. Furthermore, there is no doubt the method of forced respiration is the future treatment for many cases in which artificial respiration has been recommended. The scheme of making one breathe who needs air, and is in such a state that he cannot get it voluntarily, is a good one. We will make a broad statement by saying that all these cases die ultimately from asphyxia. This may be secondary to a paralysis of the respiratory centre, but it is, in the end, the cause of dissolution. The carbonic acid finally stops the heart, when life is at an end; but if we can institute a respiration closely resembling the normal before degenerative changes have taken place, would it be too great an assertion to say that ninety per cent. would recover? I think not. By forcing respiration we rapidly arterialize the blood, changing it from a dark ebony hue to scarlet, the secretions are started up and the poison eliminated; time alone is required. Anyone who will watch a case of opium narcosis treated with forced respiration will be surprised at the effects produced—how rapidly cyanosis vanishes, and how short a time it takes, comparatively speaking, to eliminate the poison and place the patient out of danger.

Believing that forced respiration is a valuable therapeutic agent, and that it has come to stay, and recognizing the imperfect means at our command to use it, I have for some time been perfecting a device which would be simple in construction, applicable to all cases, require no operation, and, above all, produce a respiration approaching as near as possible the natural. This I have at last completed, and have used it in three cases of opium narcosis, with the result of saving two lives without a doubt (Cases I. and II.). Case III. might have recovered. I report it to show the action of forced respiration in this class of cases.

The device, which I have named "The Automatic Forced Respirator," consists, without going into detail, of a heavy flexible rubber cup, fitting over mouth, nose, and chin, and retained either by hand or straps about the head; sometimes I secure it one way, at other times the other. In this cup is a brass tube which connects with a bellows by a rubber tube about five feet long. Inside the brass tube are two valves, which are so constructed that they automatically control the inhaled and exhaled air, one directing the inhaled air from the bellows into the lungs, the other giving exit to exhaled air to the outside through the walls of the cup. All the operator must do is to work the bellows at the rate he wishes respiration to be forced, the respirator does the rest. When this device is used we have air forced into the lungs, it is then expired as in natural respiration, as soon as pressure on the bellows is removed, from the resiliency of the chest-walls, lungs, and diaphragm, as in natural expiration. It resembles natural respiration in that expiration is a passive act.

The cup for adults fits any adult face (one is also made for children), and is rendered so nearly air-tight by a slight pressure that the lungs can be filled through it perfectly.

It has been argued that no form of bellows should be used, as the lung-tissue might be ruptured. I think this can be thrown out of medical literature forever. If air can be forced for twenty hours, or over, without causing any lung trouble whatever; if it can be used, as Dr. Fell has used it, with tracheotomy in addition, allowing more or less blood to get into the lungs, without any lung complications following, the danger cannot be very great. Lung-tissue is strong. I have repeatedly tried to rupture the lungs of a common fowl by placing a blowpipe in the trachea, with the chest laid open, giving the lungs no support. It has been impossible for me to do it. Consider the pressure the cornet-player uses to force a high note on that instrument without any damage to the lungs, and we see it is made of strong material. Again, a given pressure in the trachea is manifoldly decreased in the air-cells, owing to the expansion of the lung-tissue, and consequent distribution of pressure. The objection to the bellows, rightly used, is too trivial to be taken into consideration.

We increase the pressure of the air in the lungs at each inspiration; but this pressure is not great enough to rupture a lung, or even interfere materially with the pulmonary circulation. I have not as yet measured the pressure required to fill the lungs, but would say that it never would reach two atmospheres. We are told that more oxygen is absorbed and carbonic acid gas given off under slight pressures over one atmosphere; if this be the case, we have just this condition in forced respiration. We, no doubt, could do damage by forcing the lungs beyond their vital capacity, and keeping the pressure up, thereby crowding out the pulmonary circulation; but it is not to be supposed that the bellows, even in the most ignorant hands, would be used in this manner. The movement of the chest-wall is a guide to the amount of air which should be given; it should be a little greater than normal; respirations can be forced from fifteen to eighteen or twenty times per minute in the adult.

The bellows, as I have it constructed, is arranged so that it can be adjusted with a screw to force only a given amount of air; this adjustment is made by the physician in charge, and should depend upon the size of the lungs, and the consequent amount of air needed to produce a good inspiration; this is done so that any layman can perform the services of "pumping" as well as the physician.

Although this respirator is applicable, in all cases where artificial respiration is required, on account of its easy and prompt application, requiring no operation, and perfection in producing a respiration so near natural, I have as yet only had opportunities for using it in the three following cases of opium narcosis, in which it entirely exceeded my expectations, as well as the physicians present who saw it work.

As it is automatic one alone can use it.

It would be of especial use in drowning, because of its prompt application. Something of the kind should be owned by all vessels, bathing resorts, and life-saving crews. Many other locations might be mentioned where it might be of service, as in patrol-houses, mines, etc. One or more physicians in every city might profit by possessing one for emergency cases requiring forced respiration. One of small size would be of especial service in resuscitating asphyxiated new-born infants, thereby doing away with mouth-to-mouth inhalation, or artificial respiration in other forms.

Case I.—Mr. S——, white, aged thirty, took seven or eight grains morphine on the night of August 19, 1889, at 8 o'clock P.M., with suicidal intent. He had been drinking heavily, was naturally of a melancholy turn of mind, and had often threatened suicide, especially when under the influence of liquor. At this time, although he left letters to his relations, bidding them good by, with a brother with whom he was stopping temporarily, and had bidden the latter farewell, saying he was going to die, no especial attention was paid to him. His brother said he had fooled him so often that he took no notice of his threat. Later in the evening the brother discovered a large empty powder paper, one inch wide by three in

breadth, and a glass which had some white powder adhering to the sides. He immediately called on Dr. Dick, of East Spring Street, for an analysis. That gentleman promptly detected morphine and hastened to the scene. This was before half an hour had elapsed. The patient was walking around and firmly denied having taken the drug, saying he had thrown the contents of the glass out of the window. Dr. Dick here suggested apomorphia hypodermatically, but both brother and patient protested, the former having implicit confidence in what the latter said.

Both soon retired after the doctor had left, the brother going upstairs to bed, the patient lying down on a lounge downstairs with his clothes on. By the way, this all occurred in an undertaker's establishment.

Dr. Dick, thinking all was not right, called again at 11 o'clock, three hours after the drug had been taken. Admission was given him, when he soon found he had a bad case of morphine narcosis on hand. Patient could not be aroused in any manner. Respiration 1 or less per minute; pulse, 140; pupils contracted to pin-points; $\frac{1}{60}$ gr. sulph. atropia was given hypodermatically.

Dr. J. F. Baldwin was at once summoned, and after examining the patient thought that forced respiration was the only thing that would save him, and sent a messenger for me; $\frac{1}{20}$ gr. atrop. administered. I arrived at 1.30 A.M., August 20th. I found the physicians endeavoring to introduce a stomach siphon, which was made of very soft rubber. Attempts were abandoned shortly after my arrival.

1.30 A.M.—Pulse, 138 per minute and weak, deep cyanosis; respiration, 1 per minute, pupils partly dilated; skin moist, clammy. Automatic forced respirator applied and respirations forced at the rate of 12 to 15 per minute.

2.30 A.M.—Respirator removed. Patient made no visible effort at respiration for about three minutes; he began then to breathe at about the same rate of 1 per minute. No perceptible change the first hour. Respirator again applied, and respiration forced for about half an hour.

3 A.M.—No visible movement has been detected in the patient. Cyanosis markedly diminished; pulse, 140 per minute; skin growing warmer and very moist. Respirator again used until another half-hour had elapsed.

3.30 A.M.—Upon removing the respirator fully two minutes elapsed before there was a voluntary respiration; they then began with the Cheyne-Stokes variety, consisting of three or four spasmodic efforts, each increasing in force until the last, which filled the lungs full of air. At this time we saw the first improvement. Although the respirations were of the above-mentioned variety they had increased in frequency to one in three-quarters of a minute; surface of body was natural in color and warm; pulse about 140 per minute. Respirator again applied. In about half an hour various muscles began to twitch; he would make voluntary efforts to breathe, which, as the respirator is constructed, he could do with ease. Respirator again applied.

4.30. A.M.—A sudden jerking of the feet and hands; the latter endeavored to grasp the respirator cup; it was at once removed. Patient raised himself, stared wildly, asked for a drink, and when it was given him seemed to relish it. He immediately lay down and went into a state of stupor, from which he could be aroused by brisk shaking. Respiration, 13 per minute, deep and regular; pulse, 120. Patient was now, it was thought, getting enough air. He was watched to see that respiration did not decrease in frequency. On the contrary, however, they kept increasing in frequency. Dr. Dick remained with him until daylight, I going home. Saw him again in the morning. Was sleeping lightly when I arrived at 9 A.M. Pulse, 100; respiration 14 per minute; was considered out of danger. He made a good recovery. He, however, complained of a partial deafness in one ear for about ten days, which I attributed to the action of the air in the Eustachian tube, or to a possible rupture of the tympanum. I neglected to make any examination. At 4.30, when he returned to consciousness, and when forced respiration was discontinued, his bowels were considerably distended with air; no bad effects followed. In fact, most of the air had disappeared by 9 A.M. the next day. No lung trouble followed. It might be added that I had a probang and a sponge fastened to a silk fish-line, and was going to pass it part way down the œsophagus, and anchor it by passing it around the neck, but I was urged to try respiration without it and did so. At no time did the air in the bowels seem to impede the work, and the sponge was never introduced. However, in a case requiring many hours of assistance I do not think it would be a bad plan.

Case II.—Ethel J——, white, aged twenty months, took ten one-eighth grain morphine pills from a pill-box and swallowed them at 4.30 in the evening of August 26, 1889, making one and one-quarter grain of morphine taken. Physicians could not be procured at the time, and as a consequence no emesis was obtained. Dr. D. R. Kinsell arrived at 5.10 P.M., and found the child much inclined to sleep; he gave tartar emetic and ipecac without any effect; the child was tossed and walked about for a time, but finally went into a state of profound narcosis; $\frac{1}{60}$ grain atropia given. Dr. C. F. Turney arrived at 5.30 P.M., and found breathing 15 per minute, shallow, stertorous. Pulse could not be counted on account of rapidity.

6.15 P.M.—Skin cyanosed, breathing about 12 or 15 per minute, pulse not estimated.

I arrived at 8.15 P.M.—Respiration 10 per minute, stertorous, shallow; skin almost black, cold and clammy; pulse a mere flutter.

Respirator applied; the cup was so large that it covered the whole face, but could be held on air-tight. It was used for fifteen minutes, care being taken not to expand the lungs too much, as we had a large bellows to force with. Respirator was forced so that the natural respiration was strengthened and an extra artificial one was forced in between, so that our child was now getting double the amount of air. Dr. Kinsell had left in the meantime, fully convinced that the child would die, and had so expressed himself to the family. At the end of the first fifteen minutes there was no perceptible improvement.

9 P.M.—Respirator again applied for about fifteen minutes.

9.15 P.M.—Respirator removed. We now thought that the skin was growing brighter and warmer. Shortly after removing the respirator the respirations were up to 12 per minute, but they gradually sank back to 10. Friends here protested against further use of the respirator; they believed what Dr. Kinsell, the family physician, had told them, and did not want to see the child tortured any further. We finally, by persuasion, got them to let us proceed only for a short time, and if we saw no further improvement we would discontinue the respirations.

10 P.M.—Respirator has been used for some time; when removed, after a brief interval, the respirations are 18 per minute and strong. A bystander noticed a finger move, and we now had clear sailing; everyone was eager to see another movement, friends and acquaintances now crowded around until they became a burden, when we politely asked them to keep away, as the child needed pure air. Respirator applied occasionally for five or ten minutes at a time during the next hour; it seemed to stimulate natural respirations, as they would become more frequent and deep for a while after, then gradually sink back again, being less frequent and shallow.

11 P.M.—Decided improvement, body natural in color, respirations 28 per minute, muscular twitching very frequent and confined to toes, fingers, lips, and eyelids.

11.30 P.M.—Respirations continue strong at 25 per minute; pulse about 250 per minute; occasionally moves an arm, entirely unconscious, no effort at crying as yet.

12 M.—Respiration continues 25 per minute, child occasionally tries to cry.

12.30 A.M.—Child can be aroused, respirations about 28 per minute. A strange observation was here made, the temperature in the axilla registered 104¼° F. Child cries, but soon falls asleep again.

Dr. Turney remained over night with the child, and reports a continued improvement. Saw the child the next day, it had a temperature of 102° F. and was very nervous but still drowsy. Everything now pointed to an ultimate recovery, which rapidly ensued. No lung trouble whatever followed. When the respiration was discontinued the abdomen was very much distended with air, which condition was not visible the next day.

CASE III.—Mrs. M——, aged forty-two, a sufferer from acute attacks of neuralgia of the stomach, was given morph. sulph. ($\frac{1}{4}$ gr.) hypodermatically. After this was done it was found she had taken six one-quarter gr. pills, at intervals during the preceding four hours, without any effect.

The hypodermic was given at 1 P.M., September 24, 1889. She became drowsy and was in a deep stupor at 4 P.M., but could be aroused and would speak; pulse accelerated, pupils contracted, $\frac{1}{50}$ gr. atropia given by Dr. C. B. Ferrel, who was called in to see the case. She continued to sleep when the attendants would let her, occasionally getting a hypodermic of brandy, until twelve o'clock midnight, when respiration began to fail. Dr. Kinsell, being called into the case in the meantime, sent a messenger for me to come and use the automatic forced respirator. I arrived a few minutes after two o'clock A.M., September 25th.

Patient in a semi-unconscious state, can be aroused by vigorous shaking, will open eyes for a short time only, will not speak; pulse 120, very weak and fluctuating, respirations ten per minute, shallow and jerky, no especial cyanosis.

2.10 A.M.—Automatic forced respirator applied and worked perfectly, filling the lung at each movement of the bellows. The natural respirations were enforced, and an extra one placed in the intervals between, so that she was now practically breathing twenty times per minute.

3 A.M.—Respirator removed; one minute and a half elapsed before an attempt at voluntary respiration was made, then respiration began and continued for a short time at the rate of twelve per minute, but soon fell back to eight per minute. Respirator again applied.

3.30 A.M.—Respirator removed; in a short time patient began breathing at the rate of twelve per minute; pulse 120, strong; still in a semi-comatose state from which she could be aroused but would not speak, but would nod the head in response to questions; drank some brandy.

Fell asleep as soon as she was laid down.

3.40 A.M.—Respirator again applied and used through short intervals for the next hour.

4.30 A.M.—Patient awakens, grasps the respirator cup, rises up in bed much frightened, stares wildly, does not seem to recognize friends around her. There is now a change quite the reverse of that existing formerly. She seems frightened; when laid down she rises up, staring and gesticulating wildly. Persists in sitting up in bed, where she will occasionally nod, but soon wakes up much frightened; respirations now fifteen per minute, strong and deep.

Patient was watched for some time to see that the respirations did not decrease in frequency.

5.30 A.M.—Patient breathing fifteen times per minute, pulse 120. Still sits up in bed, occasionally nods but soon wakes up frightened; when laid down she soon rises up, looking wild and excited. She now talks, answering questions put to her. I left at this time, leaving instructions that if respirations diminished in frequency I should be called again. Dr. Ferrel reports that for some time after this she continued to be wild and excited, but her respiration did not slow up at any time. She made a good recovery, no lung trouble whatever followed. Bowels were not distended with air to any noticeable degree. It is hard to tell what would have been the end of the case had not respiration been forced, as it was failing when I arrived; it might have continued to fail and the patient died. The case was, however, seen in time, and this tendency averted.

In the first case respiration was actually forced three hours or a little less, in the second case over two hours, and in the third about two hours.

The respirator will soon be made by some Eastern instrument firm and placed upon the market.

105 EAST MAIN STREET.

ELECTRIC PROSTRATION.[1]

BY A. VAN HOFF GOSWEILER, A.M., M.D.,

PHYSICIAN TO BALTIMORE (MD.) EASTERN DISPENSARY.

THIS is a peculiar disease in persons whose duties require constant working under electric light, the recent outbreak of which is said to have caused not a little uneasiness in certain manufacturing regions.

The disease, which is known as "electric prostration," results from exposure to the arc-light, and lays siege to the subject's throat, face, and eyes. Some very severe cases are reported from Creuzot, a town in France, a large number of men being kept at work in that town in a factory where metals are heated by an electric furnace, the strength of which is over one hundred thousand candle-power, and while this is not in itself sufficient to damage the men, the intense brilliancy of the light brings on the "electric prostration."

A communication has been made by a well-known oculist of Cronstadt, a city in Russia, concerning the bad influence of the electric light upon the eye. There have come under his observation, within the past year, thirty persons suffering from a disease of the eye. The symptoms are the same in each case, and all the patients had, perforce of their employment, been accustomed to remain for hours at a time near electric-lighting apparatus. The disease is also called photo-electric ophthalmia. The patient is apt to be awakened in the night by great pains around the orbits, accompanied with an outpouring of tears, intense photophobia, and smarting pain. The first symptom is a painful sensation in the throat, together with irritation and copious discharge of tears for forty-eight hours. The chemical rays irritate the conjunctiva, resulting in actual inflammation of the eyes. The patient's skin, meanwhile, takes on an actual erythema, assuming a copper-red color, and, after several days, peels off in various places, and he is otherwise made to feel the unpleasantness of his situation.

A general outbreak of such a disease as this would involve serious consequences. The number of men whose employment brings them in contact with electric light is enormous, and is likely to increase at the same ratio as the comparatively new agent supplants the old means of illumination and becomes used as a motive power. Recent events prove that electricity has passed the experimental stage, although improvements are to be expected. Some claim that the electric light is destined ultimately to supersede gas as a lighting power entirely, and a malady springing from contact with the new power would be a grave matter.

The only remedy so far applied in cases of "electric prostration" has been the wearing of a shade over the eyes by the people affected. This relieves the direct strain upon the eyes, but does not mitigate the gravity of the other symptoms. The disease bears an evident resemblance to that known as "color-blindness," the victims of which are workmen whose duties entail a constant scanning of parti-colored lamps at night in railroad service. The electric light is far too valuable an agent to be retarded in its advancement by a drawback which medical specialists could remedy.

We know that the electric light gives the maximum of light and the minimum of heat, and yet a short exposure to the arc-light is followed by increased lachrymation, photophobic pain, swelling of eyelids, and acute conjunctivitis. The nervous symptoms and discomfort present are

[1] Read before the Medical and Surgical Society of Baltimore, October 25, 1889.

manifestly caused by this peripheral irritation. However, there are cases recorded in ophthalmic literature in which harmful effects and visual disturbances have resulted from exposure of the eyes to intense sunlight on Arctic snowbeds and extraordinary lamplight. The effect is claimed to occur through the sympathetic nervous system rather than as the result of mechanical or even chemical influences. As it is not only transitory in nature but functional in character, so the resulting reflex neuroses, anæsthesias, and paralyses vary in degree and are of short duration. It is not even proven that exposure to bright light of any kind can produce a diffused iritis, nor that acute conjunctivitis will invariably follow. No case of injury to the eye or any part of the body by the incandescent light has been reported, while the dynamo-current has caused immediate death by mechanical force.

Dr. Rockliffe[1] records a case of acute conjunctivitis which he referred to the action of the electric light, the patient having been engaged in adjusting the carbon points of a Siemen's electric lamp of three thousand candle-power, which he did without colored spectacles. After a short exposure to the light the patient was unable to perceive the people on the street, but the effect soon passed away. Much depends on the nature of the light. An excess of current produces a violent light, or a defect of current gives an orange light; both of which are less injurious than the normal white light.

Dr. David Little[2] records a case of retinitis occurring in a gentleman engaged in scientific experiments with the electric light, who had neglected on one occasion to put on dark spectacles; the box containing the light was suddenly opened, and the light fell upon his right eye. It was a great shock to him; his eyes were blinded for several minutes, and were intolerant to light of any kind for two weeks, while over the optic disk and retina immediately around there was haziness for two months. Personally, I have seen several cases of true nervous manifestations, evidently caused by high-pressure electric light. They were not known as neurasthenic individuals, nor had they, previously, defective vision. I therefore cite the case of a patient who was engaged in work with the arc-light, which necessitated his gazing with the naked eye at the light from a distance of a few inches. He awoke next day with smarting in the eyes, shedding of tears, photophobia, congestion of the conjunctiva, and nervous excitability.

The worst cases generally arise from adjusting the lamp (two thousand candle-power while burning) without goggles or smoked glass. The distance of the eyes averages about twenty inches, and with weak eyes the last-mentioned patient claimed that one minute was sufficient to produce certain inflammation, and thirty minutes increased lachrymation and swelling of eyelids. If there is no interocular trouble present, a drop of the solution of atropine gives instant relief.

All who have used the incandescent lamp in reading-rooms, libraries, or theatres have expressed great satisfaction with it. The seven hundred Edison lamps which now light the New York Hospital throughout afford a striking proof of its sanitary fitness and use, and with the aid of movable reflectors enable the performance of operations at night, and I maintain a better and more uniform temperature in the wards than with the use of gas. All incandescent lamps have globes embodied in their construction, which can be obscured and colored as desired. A brilliant effect is obtained by silvering one-half of the globe; a reflector of great power is thus obtained in an advantageous position. The light is so perfect that it need not be used close to the eyes, and the efforts of accommodation are lessened. In view of its steadiness, the iris does not suffer, though always taxed with the flickering light of gas. An opaque lamp-shade, made of glass or tin, should be used, and the light thrown down upon the work when needed. More than ever private residences are being wired for, and lighted by, electricity, and to a notable extent in growing and enterprising large towns. The high-pressure current is transformed by means of the converter to a low potential, and carried into houses at the safe and low pressure of only fifty volts, and, thus utilized in that form for incandescent lighting, is not dangerous to human life. Chandeliers and brackets have been designed for the incandescent lamp of Edison in great variety. In view of the facts that the Edison lamp will burn in any position, its absence of heat, the small size of its wires, its non-consumption of oxygen or vitiation of air, it is clearly proven to be conducive to utility and elegance, and is to be recommended, independent of commercial interest, for true sanitary purposes and genuine comfort instead of gas.

Clinical Department.

A FOREIGN BODY IN THE TISSUES OF THE NECK FOR THREE MONTHS.

Dr. H. B. Stout, of Parkersburg, W. Va., reports the following case: "Charles B——, fifteen years of age, on the 10th of last July ran against the end of a reed fishing-rod, receiving a slight wound just above and a little to the left of the pomum Adami. There was but little bleeding at the time. About two months later, in drawing his hand down the neck, he felt something under the skin. He thought there might be a sliver from the fishing-rod in the neck and consulted his family physician in regard to it, but nothing was done. On October 30th I saw him and removed a piece of the reed pole about three-fourths of an inch in length and one-sixteenth in width. It had passed through the platysma myoid muscle, and was found at a distance of about a fourth of an inch below the surface. There had been no suppuration, and the patient had never complained of any pain at all since the healing of the original wound."

PEROXIDE OF HYDROGEN FOR THE RELIEF OF BITES FROM VENOMOUS INSECTS.

Dr. Philippe Ricord, of Newark, N. J., writes: "Recently, while charging my atomizer with the full strength of fresh standard Marchand preparation of peroxide of hydrogen, at the bedside of a child suffering with diphtheria, my attention was attracted by the patient's mother, who appeared in pain and stated that, while taking up a blanket to wrap about her child, she supposed she had been pricked by a needle, and, on further examination, discovered a hornet between the folds she had touched. Thereupon I immediately directed the peroxide of hydrogen spray into the wound, the surrounding tissues, in the few seconds that had elapsed, being swollen to such an extent as to distinctly mark its site. Instantly all pain ceased, and the swelling rapidly disappeared. In this case the wound was still sufficiently open to readily admit the peroxide of hydrogen, and the destruction of the virus was, apparently, in a moment so completely accomplished that no further treatment was afterward required. May we not, therefore, infer that it is quite possible to annihilate many other poisons likewise, by the prompt application of so powerful, yet safe, an agent as the peroxide of hydrogen?"

The Number of Dentists in Germany.—According to Dr. Paul Borner's *Reichs-Medicinal Kalender fur Deutschland*, for the year 1888, there are 16,864 medical men and 514 dentists in practice among a population of 46,840,587 inhabitants in the German empire, while the number of chemists' shops is 4,671, and of hospitals 2,737. In the face of these figures it may be truly said that the dental profession is not overcrowded in the Fatherland.

Progress of Medical Science.

Method of Administering Chloral Hydrate in Eclampsia.—Dr. Blanc alludes to the difficulty of administering the drug by the mouth to patients in whom consciousness is impaired or lost, and to the drawbacks and uncertainty of its administration subcutaneously or *per rectum*. He then points out that with a patient lying on the back it is easy to introduce liquids *via* the nostrils by means of a funnel. Even in deep coma the reflexes continue to act, and, on arriving in the pharynx, the constrictors seize it and convey it to the stomach. This simple plan, however, is not exempt from inconvenience, and the author prefers to use an œsophageal tube, which may be introduced either through the mouth or the nose. The great point is to avoid the ingestion of too concentrated solutions of the drug, which is apt to set up vomiting. One part in thirty or forty, he considers, is as strong as it is safe to use. On the whole, he thinks that medical men give too little rather than too much, as a rule, and he approves of the dose being pushed to ʒ iv. in the twenty-four hours in severe cases. Moreover, chloral is not to be looked upon as exclusively a remedy in acute attacks, and the author recommends its use as a prophylactic, in cases of marked albuminuria associated with pregnancy, in doses of from forty to seventy grains daily.—*The London Medical Recorder.*

The Antiseptic Function of the Gastric Juice.—Professor Kast, the Director of the new General Hospital, Hamburg, writes on this subject in a "Festschrift" on the occasion of the opening of the hospital. Spallanzani showed, a hundred years ago, that the gastric juice has an antiseptic influence, and it has since then been proved by N. Sieber, C. Schmidt, and others that this influence is due to the free hydrochloric acid which it contains. The investigations of Baumann have shown that in healthy subjects the aromatic bodies found in the urine are due exclusively to intestinal decomposition, their amount, as united with sulphuric acid, being in a direct relation with the amount of the products of decomposition in the intestine. In Professor Kast's experiments the exact relation of the ether sulphates to other sulphates in the urine was ascertained by daily examinations, a uniform diet being given, and then copious alkalies were supplied in the food, so as to neutralize the gastric HCl; and the effect of this on the ether sulphates of the urine was examined. The conclusion is arrived at that the antiseptic function of the gastric HCl is its chief function, while its digestive function is a subordinate one. This is only true so far for the products of ordinary decomposition; the case is different with the pathogenic bacteria, many of which are highly resistant organisms. We have no means at present of estimating the amount of the chemical products due to the vitality of pathogenic organisms in the intestine. It is true that Brieger regards the diamines as due to pathogenic bacteria. But the diamines are a direct product of such bacteria, not, like the aromatic bodies found in the urine, formed from a previous substratum due to bacterial activity. Moreover, we have no clear ideas on the transition of such diamines into the urine. Hence at present we have only to fall back on the physiological action of pathogenic bacteria as an index of their existence. Baumann's and von Udransky's quantitative estimate of pentamethylene diamine (Brieger's "putrescin") in the urine, but originating in the intestine, constitutes the latest advance in this direction.—*British Medical Journal.*

"Bilious Attacks" in Neurotic Subjects.—Dr. Money says that bilious attacks in neurotic individuals are very different paroxysms from those seen in habitual or occasional over-feeders (*The Lancet.*) A clean tongue, a scanty high-colored lithatic urine, a sallow face, white motions, dilated pupils, low spirits, and absence of energy, constitute the clinical entity in many cases of "bilious attacks." These are very common in neurotic children with dainty appetites, in whom to suppose that irritation and vascular engorgement of the viscera, from over-feeding, exist, would be ridiculous. A sharp purge to these patients may do more harm than good, though it is possible to set the viscera working again by such sudden means. An inadequate liver may be the cause of a toxæmia which exerts a selective action on the mental centres originating melancholia—a view most favored by the laity, but as often incorrect. In truth, a mutual tension between the viscera and the brain exists—reciprocity rules the realms of the human body as it does the social organism. The truth appears to be that the viscera may go wrong as the result of being undercharged with nervous energy, and they simply cease to work effectively because of defective nervous energization. The correct treatment is not a dose of castor-oil, but a tablespoonful of wine at once, and a teaspoonful of sirup of the hypophosphites thrice a day for one week.

Morbid Changes in the Fauces and Larynx in Scarlatina and Diphtheria.—Having examined microscopically the fauces and larynx from ten cases of scarlatina, and as many of diphtheria, Dr. Tchernïaieff has arrived at the following general results: 1. In scarlatinal sore-throat faucial deposits represent a fine granular mass (detritus) resulting from disintegration of a simple inflammatory infiltration. In idiopathic or genuine diphtheria the deposit occurs in the shape of a peculiar hyaline net-work, which represents a product of a specific necrosis of the tissues. 2. In scarlatinal angina the faucial and laryngeal tissues themselves are found to be affected by an acute, diffuse, fairly deep vascular granulation inflammatory process in various stages of its development. In diphtheria the tissues undergo coagulation-necrosis, while inflammatory changes occur only secondarily, and by no means constantly. 3. In scarlatina the faucial blood-vessels present common inflammatory phenomena, such as dilatation, engorgement, peripheral accumulation of granulation elements, etc., while in diphtheria they are found to be attacked with hyaline degeneration. 4. In scarlatina the epithelium undergoes pronounced degenerative (retrograde) changes, while in diphtheria it remains usually intact, even in the immediate neighborhood of necrotic foci. 5. In scarlatina the faucial and laryngeal changes are generally of a more diffuse character, in diphtheria of a more circumscribed one. In the course of a discussion following Dr. Tchernïaieff's communications Professor Vysokovitch stated that some researches of his own fully support Loeffler's views, according to which the etiology and histology of scarlatinal diphtheria are quite different from those of genuine diphtheria. In the scarlatinal variety there are invariably found, in great numbers, septic streptococci, which penetrate deeply into the mucous and sub-mucous membranes, and are accompanied by deeply seated foci of necrotic disintegration. In true diphtheria there are detected microbes of a different species—namely, Klebs-Loeffler's bacilli, which, in addition, lie only in the upper and middle layers of false membranes, but never reach the level of the subjacent mucous membrane itself. Dr. Iatzevitch, of St. Petersburg, similarly thinks that scarlatinal diphtheria is essentially different from the genuine diphtheria. As an indirect proof he adduced the fact that, having happened to observe, at a Poltava village, in 1887, a scarlatinal epidemic, attacking 120 patients, and lasting about four months, he met with scarlatinal sore-throat in as many as twenty-five per cent. of the cases, but he did not come across a single instance of genuine diphtheria about the locality during the whole period mentioned.—*Journal of Laryngology.*

Insane Hospital in Chicago.—The County Commissioners propose to erect an insane hospital on the lake shore, some miles north of the city; cottage plan.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place

New York, February 8, 1890.

FOR DIPHTHERIA IN YOUNG CHILDREN.

THE means at hand for the successful treatment of diphtheria of the fauces in children who are old enough to submit to treatment without resistance, are amply sufficient in most cases. It is generally quite easy to keep the membrane from excessive development, or even to free the surfaces of the throat entirely from it, by the constant use of gargles or sprays, or direct application with the hand of solutions which dissolve the membrane, yet do not irritate the tissues. In the case of infants or of children who struggle violently against local treatment the practitioner is driven to despair. The exhaustion of the patient produced by frequent battles with its nurse, and by the violent crying spells which are excited, as well as the incompleteness of the application under such trying circumstances—especially when a trained nurse is not employed—soon convince him that it is better to give up energetic local treatment, and to trust to medication of the air of the sick-chamber and to internal remedies.

It is in view of such difficulties in treatment that the suggestions made by Dr. Burghardt (*Wiener Med. Wochensch.*, September 28 to October 5, 1889) seem worthy of attention. Before the year 1882, he had treated diphtheria of the fauces with the various medicaments in vogue, but only too frequently his efforts had been fruitless. Observing at that time the success which followed the application of sulphur to vines affected with the disease produced by the oidium vitis, and realizing the germicide, and, what is of even more importance, the tonic virtues of quinine, he determined to apply these two drugs to the diseased surfaces in the form of a fine powder, thus combining in one application the advantages to be gained from both local and general treatment. Although sulphur and quinine have often been recommended for use separately, he knows of no one who has used them together in this way.

He rubs equal parts of sulphate of quinine and washed flowers of sulphur together into a very fine powder. One and a half to three grains of the powder must be blown upon the diseased parts with a common insufflator, the mucus having been previously removed from the throat by a gargle or a drink of water. After the mass of powder has been blown upon the parts most diseased, that which remains in the insufflator should be blown upon the adjacent surfaces, into the posterior nares, into the recesses of the larynx, and into the anterior nares. This should be done twice a day, both during the disease and, with smaller doses, for some days after the disease has disappeared. As the powder has no odor, the little patient makes no more objection to its application than to any form of local treatment or examination. For an hour and a half after the application nothing solid or liquid should be taken into the mouth or swallowed by the patient. Since 1882 he has treated in this way 33 cases, in patients from one to twenty-four years of age. The type of disease in 1884 was very severe, with many fatal cases throughout the city. Whereas by other methods he had lost almost three-fourths of his diphtheritic patients, by this method he brought these thirty-three consecutive cases safely through. In some instances the diphtheritic membrane covered the whole surface of the mouth, and had spread even to the lips and nostrils.

Since he has had such good results with this insufflation, he has entirely given up inhalations. When it is advisable he recommends, with the insufflation, cold external applications to the neck, sucking of ice, and gargling with solutions of chlorate of potassium or lime-water. With children under three years of age it is often impossible to use these additional applications. Between the insufflations he gives tincture of iron, wine, and brandy, as tonics; and if blood-poisoning appears, stronger doses of iron, with ergot and lemon-juice. Such blood poisoning appeared in only one of the thirty-three cases, in which the family would not permit him to see the patient daily.

He keeps up the insufflations until all glandular swelling has subsided. All of his cases were seen early in the attack. In most cases, as soon as insufflation was begun the fever fell and the debility gradually disappeared. The membrane separated in bits, and though a second or third membrane occasionally formed, the process gradually ceased. The patients always felt fresher and more calm, with better appetite and less painful deglutition, after each insufflation. There were no complications nor sequelæ, except in two cases, where middle-ear catarrh and perforation of the drum occurred.

The insufflation must generally be made by the physician, as he must first locate the membrane, and must apply the powder quickly and accurately.

Dr. Burghardt presents his method not as absolutely sufficient, but as well worth testing.

THE STATE MEDICAL SOCIETY—A CRITICISM.

A CORRESPONDENT sends us the following sensible suggestion: "Criticism at times provokes reform. There is room for reform in the management of the scientific business of the State Medical Society. This, I doubt not, is the unanimous verdict of those present at the initial session of this society for the current year. Fully two hours were consumed—some think were wasted—in the discussion of executive business, leaving two hours for the reading and discussion of seven papers. These papers were doubtless all carefully prepared, and the readers, at more or less inconvenience, went to Albany in the hope that some addition to science might be the outcome of the discussion. The attempt to crowd this number of papers and their discussion within the time limit could have, of course, but one result—a farce. No

one present will forget the manner in which the presentation of the papers was blighted in the egg, so to speak, and discussion was strangled. Very likely the officers of the society regret more than anyone else this parody on the transaction of scientific business. It rests with them and their successors to devise the remedy. Executive business is important, but scientific business should not on this account be crowded to the wall."

This is not the only complaint in this direction which has been made to us, and it behooves those who manage the society that there is more system for the carrying on of scientific work, and less time given to wire-pulling and log-rolling for offices.

COLUMBIA COLLEGE CELEBRATION.

At the installation of Seth Low as president of Columbia College, on Monday last, the medical profession of this city was well represented. Among the distinguished guests upon the platform, side by side with judges, statesmen, presidents of colleges, soldiers, clergymen, and men of letters, sat those of our own profession who had worked long and faithfully in the grandest calling of all. The gathering, taken altogether, was the most notable one which has assembled for a long time upon any platform, and did honor to the college, to the noble cause which it represents, and to the new president, whose acceptance of the charge promises so much for the future of the grand old school. The medical profession is proud of the opportunity of lending its influence to the good cause, and points with just pride to the fact that two representative men from its ranks are on its board of trustees. No more fitting men than Drs. George L. Peabody and William H. Draper could have been chosen for the positions, and none who are better able by their wide learning, distinguished reputation, and wise counsel to add weight, wisdom, and power to the government of old Columbia.

FOR THE PREVENTION OF BLINDNESS.

Of the different bills now before the New York State Legislature, of interest to the medical profession, there is one which certainly deserves favorable consideration : this is entitled an Act for the Prevention of Blindness, and provides that every midwife or nurse who has charge of a case of purulent ophthalmia of infancy shall be obliged to report the same promptly to the local health physician, and failure to do so is to be punished by a considerable fine, or punishment, or both.

According to the report of a special committee on blindness appointed by the State Society, it appears that between 1870 and 1880, while the population of the entire United States increased 30.09 per cent., the number of blind increased 140.78 per cent ; during the same time, blindness in New York State increased 8.2 times as rapidly as the population, and during the last five years of that decade it increased 13.7 times as rapidly. The report of this committee gives due weight to the fact that such statistics are apt to be misleading, but concludes that in all probability the increase of blindness is really much more rapid than the increase in population. However this may be, there are two undisputed facts which of themselves would be sufficient to warrant the adoption of any such measure as this act contemplates. In the first place, it has been established by a large number of examinations of the inmates of blind asylums in different parts of Europe, as also by similar investigations made at the New York State institutions for the blind at Batavia, and in New York City, that about one-fifth of all these cases of blindness are those which have resulted from purulent ophthalmia of infancy. Next we have the clinical fact that, when these cases receive proper treatment in the early stages of the disease, recovery results in all but an exceedingly small proportion. In other words, the destruction of the eye from purulent ophthalmia must now be regarded almost invariably as due to carelessness or neglect. The object of this legislation is, therefore, to forcibly impress upon nurses and midwives the importance of the disease, and by calling the attention of the parents to the fact that the slighter forms of the inflammation are something more than "a cold in the eyes," as it is often termed, to have them seek for their children that medical advice and attention which this class of cases promptly demands.

THE ABUSES OF UTERINE TREATMENT.

The Medical Record has always tried to deal fairly with its friends, the specialists, as well as with its friends, the general practitioners. It has felt, to be sure, a keener sympathy with those of the latter class, for it is they who, after all, give the character to our calling, and upon them the great burden of medical work falls. Everything that can lend advantage to the general practitioner, that can help him in his daily work and make his life more fruitful and successful, we have studied to encourage. We cannot be unmindful that most of scientific progress, and much of the practical advances in the technique of our art, are due to the work of specialists. Yet with this work there has too often developed a tendency to narrowness of view, and to the application of some special treatment to an excessively wide range of diseases; and also of finding in unoffending organs pathological processes that were of extremely little moment until brought to the attention of the patient.

We have thought sometimes that our gynecological friends were to be specially condemned in this respect. And we have for several years lamented the gynecological furor which has seized the American profession. An esteemed contemporary has even referred to this journal as anti-gynecological. The criticisms which we have uttered in the past are all mild, however, compared with those now frequently appearing in contemporary journals, sometimes from gynecologists themselves. And we take pleasure in quoting the concluding words of Dr. William Goodell in an article on "The Abuses of Uterine Treatment." He says :

"From a large experience I humbly offer to the reader the following watchwords as broad helps to diagnosis :

"1. Always bear in mind what another has pithily said, that 'woman has some organs outside the pelvis.'

"2. Each neurotic case will usually have a tale of fret or grief, of cark and care, of wear and tear.

"3. Scant or delayed or suppressed menstruation is far more frequently the result of nerve-exhaustion than of uterine disease.

"4. Anteflexion, *per se*, is not a pathological condition. It is so when associated with sterility or painful menstruation, and only then does it need treatment.

"5. An irritable bladder is more often a nerve symptom than a uterine one.

"6. In a large number of cases of supposed or actual uterine disease which display marked gastric disturbance, if the tongue be clean the essential disease will be found to be neurotic, and it must be treated so.

"7. Almost every supposed uterine case, characterized by excess of sensibility and by scantiness of will-power, is essentially a neurosis.

"8. In the vast majority of cases in which the woman takes to her bed, and stays there indefinitely, from some supposed uterine lesion, she is bedridden from her brain and not from her womb. I will go further, and assert that this will be the rule, even when the womb is displaced, or it is disordered by a disease or by a lesion that is not in itself exacting or dangerous to life.

"Finally, uterine symptoms are not *always* present in cases of uterine disease. Nor, when present, and even urgent, do they necessarily come from uterine disease, for they may be merely nerve-counterfeits of uterine disease."

THE BOGUS MEDICAL DIPLOMA BUSINESS IN AMERICA.

The *British Medical Journal* has devoted a long editorial to a presentation of the sensational story of the bogus medical diploma business in this country published in a Boston daily paper. We regret to see this, for the reason that in all probability the article has but the very flimsiest basis of fact.

Many of our States have medical registration laws, which call for a rigid scrutiny of diplomas, and the existence of bogus college business would soon be detected.

THE HYDERABAD CHLOROFORM COMMISSION.

The Second Report of this commission, of which Dr. Lauder Brunton, of London, was president, has been made, and the results appear to contradict totally previous views held as to the action of chloroform upon the heart and respiration. Experiments were made upon five hundred animals; they began in October last, and the final report, just published in *The Lancet*, shows that the respiration is always stopped before the heart. Dr. Brunton acknowledges the change made in his own opinion by his recent work, and the conclusion to be drawn is that death from chloroform is preventable. *The Lancet* says: "From the report it will be seen that the discrepancy between the views of different schools arises from the fact that sufficient consideration has not been given to the conditions under which the chloroform is given. Although it may paralyze the heart if applied directly to it, yet this condition does not occur in practice, for here it is neither applied to that organ nor yet is it blown forcibly into the lungs. It is inhaled by the patient, and when this is the case it stops the respiration before the heart. The practical outcome of the research would appear to be that deaths from chloroform are not inevitable."

It is possible that the report in question will seriously affect the practice of surgeons, but we doubt if it will do so before further evidence, both experimental and clinical, is given to the profession.

"WHAT LA GRIPPE REALLY IS."

We have received a copy of *Kate Field's Washington*, with a request to please notice an article entitled "What la Grippe Really Is." We are pleased to make the notice requested.

The article in question resolves the secrets of *la grippe*, and tells us in simple language what the most expert bacteriologists of the world have, as we had supposed, failed to discover. The disease is due to infusoria discovered by Dr. J. H. Salisbury in 1873. The pictures of the parasite in question are given with considerable artistic skill. Of course, the presence of the pictures settles it; or at least seems to do so in the mind of the writer of the article, since no other proof is given. As a matter of fact, however, there is not a fragment of evidence that those parasites cause the "grip."

The organism has not been cultivated or inoculated, or put to even the simplest tests which modern bacteriology demands for proving their specific character.

The announcement in a lay journal, that "*la grippe* really is" due to the Salisbury infusoria, spreads abroad an error which perhaps does no serious harm, but reflects very much upon the need of a scientific editor for *Kate Field's Washington*.

SANITARIANS AS ALARMISTS.

Even the most despondent pessimist in our profession is forced to admit that the science of preventive medicine is making great strides in this latter part of the nineteenth century. Many indeed profess, and perhaps not without some excuse, to see in this direction the only signs of real progress, and they turn despairingly from the attempted cure of disease to plunge with ardor into the study of its prevention. We look with admiration upon the workers in this field, and we rejoice with them in every triumph which they have to record; but we cannot refrain from calling attention to an error into which they are prone to fall, and whereby they endanger greatly the immediate success of their labors. They are apt to go too far and to attempt to prove too much.

Men are willing to be scared a little, but they will not allow themselves to be scared too much. They are reasonable also, and are ready to put up with many inconveniences for the good of the community, but their patience and their faith have limits. When one thing after another is forbidden simply because some sanitarian says that it contains the germs of disease, they begin to doubt. They see that their fathers drank ice-water in moderation and yet lived to a good old age, although they are now told that ice holds many bacteria which only await liberation to work destruction among the sons of men. They have seen people riding in sleeping-cars for many years, but are now informed that it is only at the peril of their health that they ever pass a night in these pest wagons. They have been accustomed to look upon a sea voyage as health-giving, but are now told that it is almost a miracle if one reaches the shore without having received into his

lungs the germs of consumption. It is no wonder that they become incredulous after a time and refuse to accept any advice from the sanitarian, especially if such advice runs counter to their material interests.

Much, if not most, of the opposition which health officers have to contend against comes from individuals or corporations whose interests are threatened, and the only effectual way of overcoming such opposition is through an appeal to public opinion. Laws are useful and necessary, but they are of comparatively little avail unless backed up by the intelligent approval of the public. We may gain the support of the people by appealing to their reason and common sense, but not by working upon their fears and conjuring up causeless alarms, which their own experience tells them are existent chiefly in the mind of the too zealous sanitarian.

THE DISPENSARY ABUSE ONCE MORE.

IT seems an almost hopeless task to protest any further against injury done to the great mass of the profession by the dispensaries in this and other towns throughout the country, so much has been said and written against this abuse, and so little has been gained. Indeed, we might rather say so much has been lost, for the evil has abated not one jot, but has steadily increased, and the bread-and-butter problem is daily growing more perplexing to the young practitioner.

Of course there are arguments in favor of the existence of dispensaries, and we cheerfully admit the force of some of them. A few institutions of this kind are necessary in a teaching centre in order to obtain material for educational purposes. The era of didactic teaching is drawing to a close, and the necessity of clinical instruction is now universally recognized. The latter is impossible without a supply of material, and the dispensaries are perhaps needed to keep up this supply. If this were all, if the college dispensaries admitted only so many patients as were necessary to meet the demands of clinical instruction, and if they were careful to exclude the kid-glove and sealskin paupers, there would be but little opposition to them. But there are others, not necessary to mention, which have no such excuse for their existence. They are not available for the purposes of clinical instruction, and live only to gratify the vanity of their managers, who love to be looked upon as philanthropists, and to be lauded in public for their devotion to the cause of sweet charity. Everyone knows—at least every medical man knows—that there is no charity in such places, and that the sick poor would be just as well or better treated were every such dispensary razed to the ground.

What is the remedy for this evil? Protests are useless, arguments have effected nothing, and petitions would be unheeded. If the young practitioner, or the old one either, for that matter, wants to correct this abuse, he must act, he must combine with his fellow-sufferers and see what he can do for himself in the matter. Let him fight fire with fire. If it is allowable for a number of physicians to treat patients free during certain hours at a dispensary, why is it not equally permissible for the individual to do so? Let every physician who wishes to increase his clientèle and to make himself known in a legitimate way to a larger circle, have certain hours of certain days during which he will treat gratuitously the deserving poor, and let him see to it that the fact becomes known in his neighborhood. It will not be long before he finds himself with plenty to do in these hours, and if he does his best for these free patients he will soon find his waiting-room comfortably filled during his paying hours. He will have the satisfaction of knowing that he is doing good to the really poor, while, at the same time, the bread that he casts upon the waters he will see coming back to him in abundance at every turn of the tide.

This is no wild or revolutionary scheme, and there is nothing in its execution that can in any way lower the dignity of the profession of medicine. It is not even new, for it has been proposed and carried out many times. It is a practical measure for dealing with the question of dispensary abuse, and if it were adopted generally by physicians everywhere, the *dies iræ* of the useless dispensary would be at hand, and it would speedily pass to the well-deserved purgatory of an innocuous desuetude.

News of the Week.

Dr. Edwin Webb, who was probably the oldest physician on Long Island, died at his home in Hempstead, January 29th, aged eighty-six years. He was born in England. He studied medicine at the College of Physicians and Surgeons, N. Y., graduating in 1825.

Alleged Cure for Hydrophobia.—The daily papers announce that Dr. Bokai, a professor at the Klausenburg University, claims to have discovered an absolutely certain antiseptic remedy for hydrophobia, destroying the virus at the seat of the bite. It consists of a solution of chlorine, bromine, sulphurous acid, and permanganate of potash, with oil of eucalyptus.

Treated at Pasteur's Institute.—According to the *Bulletin Médical*, the last death from hydrophobia which occurred after inoculation at the Pasteur Institute took place on the 21st of August last—that is to say, five months ago. Since then 850 persons have been treated at the Institute, and not one death has occurred among them.

Beer and the Influenza.—In Munich, the daily consumption of beer has been reduced by upward of thirty thousand gallons since the influenza broke out.

The Hospital Book and Newspaper Society of this city is a useful charitable organization, having for its object the distribution of reading matter among the sick and suffering. During the past year it has distributed 8,034 books, 20,701 magazines, 37,696 illustrated and weekly papers, 6,171 Christmas and Easter cards, and 133,611 newspapers.

The Increase of Insanity in New York State.—The State Board of Charities, in its recent annual report, says that the increase in the number of insane in the State has averaged about six hundred and sixty each year for nine years. That is over sixty-two per cent., against an estimated increase in population of eighteen per cent. Besides the 15,482 insane in institutions, the Board estimates that there are enough in family care to raise the whole number to 20,000, or 1 for every 300 persons.

A Board of Medical Examiners for Washington, D.C.—Senator Ingalls introduced a bill in the U. S. Senate establishing a board of medical examiners for the District of Columbia. The bill provides that the board shall consist of ten physicians or surgeons, three dental surgeons, and in addition five homœopathic practitioners of medicine. The term of office shall be four years. The members are to be appointed by the District Commissioners, and the board is to prescribe rules and regulations for the examination of all candidates for the practice of medicine appearing before it. The board is to examine all persons of either sex appearing before it, and when an applicant shall have passed a satisfactory examination the president of the board shall grant to such a person a certificate to that effect. Examinations are to be practical, and no candidate is to be kept waiting for an examination for a longer period than thirty days. Re-examination can be held at the expiration of three months. Any person obtaining a certificate from the board shall register the same at the health office, and shall then be allowed to practise the branch in which he has passed the examination; and no person shall commence the practice of medicine, surgery, or dentistry in the District who has not first obtained such a certificate. No person not a registered practitioner of medicine shall offer for sale any drug, nostrum, etc., without first obtaining a certificate from the board setting forth that the said article may be offered for sale. Violations of the act are to be punished by a fine of not less than $20 nor more than $100, or by imprisonment for not less than 30 days nor more than 365 days, or by both. Nothing in the act is meant to affect the business of registered pharmacists, or of physicians called in for consultation from other cities.

The Need for Ambulance System in Chicago.—The city authorities are considering—unfavorably, it is to be hoped—the erection of emergency hospitals in different quarters for accident cases. Physicians generally seem of the opinion that the need is not for more hospitals—of which Chicago has an ample supply scattered over the city—but for an ambulance service such as obtains in New York, for example. At present Chicago has absolutely nothing for the care and transfer of emergency cases except the patrol wagon manned by three policemen only. The recent death of a woman without medical attendance, forty-eight hours after application had been made to the proper office for pauper relief, the "County Agent's," has called public attention to the inefficiency and red tape of that office. The application was made one morning; next day the official visitor investigated, turned in an approval that night, and a physician sent the next morning found that the patient had died a few hours before his arrival. The county has contracts with various charitable organizations—dispensaries—to visit the county poor; the physicians respond promptly, but, as in this case, much time may be consumed by the machinery of the office. Improvement is promised.

Nothing New to be Said about the Influenza.—In response to a letter from the editor of the *Deut. medicin. Wochenschrift*, asking for a contribution to the subject of influenza, Professor Hirsch, the celebrated epidemiologist wrote: "My dear Colleague: Just recovered from a very unpleasant attack of influenza. I hasten to express to you my regret that I cannot comply with your request regarding a critical report on the prevailing epidemic for your valued weekly. The news of the epidemic hitherto to hand are so scanty and so unreliable that it might be labor in vain to attempt to form out of them a faithful picture of its course and character, and it would really be hardly worth while to collect news about it, for I am convinced that it does not essentially differ in any respect from all the influenza epidemics that have hitherto been observed. The great sensation caused by the appearance of the disease is due simply and solely to the indifference of the great mass of the medical public to all that history teaches. The culminating point is the assertion of the French physicians that the epidemic in Paris is dengue, but matters are not much better among ourselves. What I had to say about influenza I said in the second edition of my 'Historico-Geographical Pathology,' and there is nothing new to hand. With best regards, yours most truly, HIRSCH."

London Doctors and the Lay Press.—A lady reporter has been interviewing, or rather calling, upon some of London's popular physicians in the guise of a patient. The *Medical Press* says: "The necessity of a 'silver key' at Sir Morell Mackenzie's, the impossibility of seeing Sir Andrew Clark at all 'without an appointment,' and the 'bowed form' of Sir Oscar Clayton, brought about, as in the case of Sir Pertinax McSycophant, by much 'booing,' are all life touches which will be universally recognized; but the description of a visit to Dr. Robson Roose is too delicious to be so briefly dismissed. His condescension in seeing the patient after his hours, his reassuring affability, his congratulations on her having escaped falling into the hands of 'unprincipled' persons who would 'inconsiderately,' he did not say intentionally, have unduly frightened her, are fitly capped by the final question in parting as to how the lady came to consult him at all. The interrogation of a physician who has sixty patients under his hands with the prevailing epidemic, 'from Cabinet Ministers downward,' as to whether she came '*through a chemist*,' is a touch worthy even of a Molière."

The Metropolitan Medical Society is the title of a society which has been organized in New York, and will hold its meetings at the residence of members on the first and third Thursdays of each month, with the exception of July and August. Dr. Charles Schram, 136 East Eighty-second Street, is the corresponding secretary.

Receiving Hospital, San Francisco.—Dr. Robert Bunker, formerly physician at the Old People's Home, has been appointed by the Board of Health as Assistant Surgeon in the Receiving Hospital.

Directory for Nurses.—The Kings County Medical Society maintains at its rooms, 356 Bridge Street, Brooklyn, a directory of three hundred and eleven nurses in the city. Every one of those registered was engaged during the recent epidemic, and forty more could have been employed. This registry is conducted without any expense to the society, and the person in charge also cares for the reading-room and library.

The Chicago Polyclinic has a new plant worth $40,000 and is consequently in a very flourishing condition.

Hospital for Infectious Diseases in Chicago.—Several ladies of means have undertaken to supply a "long-felt want" in Chicago—a hospital for infectious diseases, particularly diphtheria and scarlet fever. Such cases are turned away from all existing hospitals. The amount of subscription already received indicates success.

Women Doctors in Germany.—An association of German ladies, at a meeting a short time ago, passed a resolution agreeing to a petition being presented to the divers German governments, praying for permission to be granted to women to study medicine. The petition so far has been flatly refused by Prussia, Wurtemberg, Saxony, and the Duchies of Hesse-Darmstadt and Saxe-Weimar.

The Death-rate of this City was last week 25.52 per thousand, as against 28.46 for the preceding week.

Tenement-house Mortality.—Dr. R. S. Tracy, the Registrar of Records of the Health Department, has submitted to the Board of Health a report on the tenement-house mortality of 1888, supplementary to a report made by him on the same subject in June, 1889. The doctor says that since the beginning of 1880 all tenement-houses have been constructed under the supervision of the Health Department, and the construction of rear tenements has not been permitted. The records show these things: 1. The death-rate was lower during 1888 in houses standing singly on a lot than where there were both front and rear houses. 2. The death-rate in houses built since 1888 was lower than in houses built before that time. 3. The death-rate was remarkably lower in houses built since 1886, both for adults and children. 4. The highest death-rate in the district south of Fourteenth Street and west of Broadway was below Reade Street. 5. The highest child death-rate was in the Ninth Ward, and the next highest in the Fifteenth. 6. The highest death-rate of persons over five years of age was in the First and Third Wards, and the next highest in the Eighth.

The Sick and Dependent Classes of New York.—The State Board of Charities estimates that the number of inmates in all the institutions for sick and dependent classes, October 1, 1889, was 67,781, of whom 15,482 were insane, 20,949 orphan and dependent children, 1,330 idiotic and feeble-minded, 584 epileptic, 657 blind, 1,328 deaf and dumb, 4,765 juvenile offenders and delinquents, 973 disabled soldiers and sailors, 3,782 hospital and infirmary patients, 7,007 aged persons in homes for the friendless, and 9,980 in almshouses. During the year medical and surgical relief was furnished to 443,341 outdoor patients.

Ambulance Service in San Francisco.—A movement is on afoot in San Francisco to establish a much needed ambulance service in that city.

Presbyterian Dispensary.—Dr. Henry C. Coe has resigned from the Presbyterian Dispensary, New York.

A Maternal Impression.—A writer in the *Medical Brief* reports a case of spina bifida, in which the midwife alleged as a cause that the child was marked in consequence of the mother having worn a bustle.

Exempting Doctors from Taxation.—A bill exempting physicians from personal taxation is before the Legislature of Mississippi. It meets with much opposition on the ground of class legislation.

To Care for Lepers.—Miss Amy C. Fowler, whose religious name is Sister Rose Gertrude, has taken the place of Father Damien, the leper martyr, and will shortly sail for Molokai, of the Hawaiian group, and enter upon her life mission. She is a native of England, twenty-seven years of age, and a recent convert of the Roman Catholic faith. Miss Fowler will have a salary from the Hawaiian Government. She expects to have but little use for the money herself, but intends to devote it to the benefit of the hospital and its patients.

The Cincinnati Polyclinic.—Dr. C. S. Ayres has been elected President of the Cincinnati Polyclinic Graduate School of Medicine.

Obituary.

CHARLES S. WOOD, M.D.,

NEW YORK.

Dr. Wood was born in Litchfield, Conn., February 27, 1825. He taught school after he became of age, at the same time studying medicine with Drs. Beckwith and Seymour, of Litchfield. When he was twenty-six years of age he received his degree from the Jefferson Medical College, having previously taken a course of lectures at the College of Physicians and Surgeons, New York. He began the practice of his profession at Greene, Chenango County, this State. In 1862, however, he joined the Army of the Potomac, having been commissioned an Assistant Surgeon in the Sixty-sixth New York Volunteer Infantry. In a year he was promoted to Surgeon of the regiment, and on September 9, 1863, he received his commission as Surgeon, United States Volunteers.

He participated in all of the battles of the Army of the Potomac until about the time when he was transferred to the staff of General Wright, serving at San Francisco and Sacramento. He took charge of the general hospital at the Presidio, San Francisco, and at the close of the war he was ordered to Alcatraz Island, in San Francisco Bay. He returned to New York in 1867, and has since lived here.

At the time of his death Dr. Wood was President of the New York County Medical Association, having been just elected to his second term. He had served for two years as President of the Medico-Legal Society, and was a Fellow of the State Medical Association, the American Medical Association, a Fellow of the New York Academy of Medicine, and ex-President of the Northwestern Medical and Surgical Society of New York.

Dr. Wood was well known to the profession as ranking with the most industrious, and as being very active in society matters. He was one of the founders of the New York State Medical Association, and took an unusual interest in its success, being one of its representatives at the Ninth International Medical Congress. He also wrote occasionally for the medical press, chiefly on practical and therapeutical subjects, and had a bias for medical jurisprudence, surgery, and physiology. A quiet, modest man, with an exceptional knowledge of parliamentary usage, he always made a satisfactory society president.

His health had been failing for some time past, although his death, which occurred at his residence, on the first instant, and was due to chronic nephritis, was somewhat of a surprise to his many friends.

Society Reports.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Eighty-fourth Annual Meeting, held at the City Hall, Albany, February 4, 5, and 6, 1890.

[By Telegraph to the MEDICAL RECORD.]

DANIEL LEWIS, M.D., PRESIDENT, IN THE CHAIR.

FIRST DAY, TUESDAY, FEBRUARY 4TH—MORNING SESSION.

PRAYER was offered by Rev. Dr. Raymond.

President's Address.—In his inaugural address the President suggested that members and county societies give their orders for the volume of "Transactions" in advance of its publication; and that presidents of county societies should be made members of the State Society by virtue of their office.

The Indigent County Insane.—Every member should do all in his power to have the bill now before the Legislature passed, providing for State care of county indigent insane.

State Board of Medical Examiners.—It was hoped the bill providing for a State Board of Medical Examiners, which will be presented for approval by the Society on Thursday, will receive unanimous support. He recommended the New York Physicians' Mutual Aid Association to the members of the profession throughout the State.

Committees.—*Business Committee*—Drs. George H. Fox, Henry Flood, and Herman Bendell. *Committee on Credentials*—Drs. Charles Jewett, C. M. Culver, and Seneca D. Powell. *Committee on the President's Address*—Drs. W. W. Potter, of Buffalo; A. Jacobi, of New York, and A. Vanderveer, of Albany.

Report of Committee on By-laws.—Among other changes recommended was that attendance on only two annual meetings be necessary to make members eligible to permanent membership. They also recommended the appointment of a "Finance Committee," to consist of the president, secretary, and treasurer, to which should be referred all matters relating to the expenditure of money.

The committee recommended that where the Nominating Committee failed to agree on the three highest officers of the Society, they report the three receiving the highest number of their votes, from among whom the Society shall make its choice.

The report was ordered printed for distribution.

Report of the Committee on Revision of the Pharmacopœia.—Dr. Stoddard read the report, which was one of progress. It was accepted, and the committee, consisting of Drs. Stoddard, Johnson, and Rice, were made delegates to the convention to be held at Washington in May.

Report of Committee on Prize Essays.—Dr. George F. Shrady sent the report, which was read by Dr. Beach. But one essay had been submitted, and this, while deemed meritorious, did not fully comply with the conditions.

The time for reading papers was limited to fifteen minutes, for discussion to five minutes.

The Time Element in Saving the Perinæum.—DR. ROBERT L. DICKINSON, of Brooklyn, read the paper, which was a plea for sufficient time in perineal distention. The need of this was shown by experiments on the cadaver, but particularly by clinical observation, his paper giving a list of one hundred and forty-seven cases. The ruptures in primipara usually given was about twenty-one per cent., in nullipara about fifteen per cent. Out of bad hospital cases, including the hydrocephalic, etc., about thirty-three in number, he had had only about twenty-four per cent. of injuries of the perinæum. Rapid, forcible delivery was shown by statistics to give a large percentage of injuries.

Injury of the Perineal Body.—DR. H. C. COE had adopted the views enunciated by Dr. Emmet, that injury of the perinæum did not necessarily imply rupture of either the skin or mucous membrane, but simply of the body of the perinæum.

The Injury Takes Place Before the Perinæum is Distended.—DR. EMMET explained his views, and said the injury usually took place before the perinæum (skin and mucous membrane) was put on the stretch. The ordinary method of supporting the perinæum by the hand did actual harm.

Drs. Grandin, Potter, and Jewett also objected to supporting the perinæum, by which the progress of the head was retarded.

Extra-uterine Tubal Pregnancy.—DR. H. D. V. PRATT, JR., of Elmira, described a case, and said it was the only one on record of retro-uterine pregnancy where the cyst containing the fœtus was of such size as to cause complete obstruction of the bowel by pressure, for the relief of which its removal was demanded, the operation resulting in complete restoration of the patient. Electric puncture was made through the upper and posterior vaginal wall, through which the child was extracted. The placenta came away eight days later.

What are the Rational Limitations of Intra-uterine Therapeutics?—DR. A. F. CURRIER, of New York, in a paper on this subject, divided his cases into two classes, those of diseases of the cervix and those of diseases of the body.

The conditions of the cervix requiring therapeutic measures were subdivided into those of non-traumatic congestion, traumatism, infection, and malignant degeneration. Some of these were suitable to treatment by astringents (including electricity), others to the curette, others to plastic operations, and still others to more extensive removal of tissue.

Therapeutics of the Mucous Membrane of the Body.—These required entirely different considerations. The diagnosis was often very difficult. He divided intra-uterine therapeutics as follows: irrigation; solutions, pastes, and powders; treatment by the curette. He had discarded the stem pessary because likely to do harm.

No such Disease as Endometritis.—DR. T. A. EMMET did not believe in endometritis, and was opposed to intra-uterine applications.

DR. COE had recently lost one of his most important cases by intra-uterine medication, and was coming around to Dr. Emmet's views.

DR. CURRIER thought endometritis could not be denied to exist, when by that way alone an acute gonorrhœal inflammation could pass to the tubes.

Remarks on the Use of the Uterine Curette.—DR. WALTER B. CHASE, of Brooklyn, in a paper urged the use of the curette for removal of the placenta in miscarriage, in conditions of puerperal septicæmia, retained placenta, or decomposing blood-clot; also for scraping away hypertrophic tissue of the endometrium following labor; also for removal of hypertrophic fungosities.

The paper was discussed by Drs. Currier and Jewett.

Malignant Disease of the Corporeal Endometrium.—DR. H. C. COE read the paper, which will appear in a future issue.

It was discussed by Dr. Currier.

The Indications for Operation in Diseases of the Uterine Appendages.—DR. EGBERT H. GRANDIN read the paper, the first part of which showed the abuses of the so-called Tait operation, which was introduced in this country in 1882. He believed the time was more than ripe when a sharp line should be drawn between cases which could only be relieved by an operation and those in which comfort at least would follow non-operative measures. He was convinced that frequently we could save rather than mutilate. By mutilation was meant cases where slightly thickened ovaries, slightly thickened tubes, or tubes containing a little cloudy serum were removed.

The vast statistical data was of little value, for being mostly of hospital cases the histories were not followed up.

Physical signs of disease of the ovaries demanding removal could scarcely be determined by the pathologist, much less by the general operator. Nor were the symptoms alone reliable in deciding on the question of operating.

When to Operate.—He was in favor of removing cystic ovaries when the tumor was observed to be increasing in size. It was not so easy to say when the tubes should be removed. The cases might practically be divided into those of catarrhal salpingitis, hydrosalpinx, and pyo-salpinx. Simple catarrhal salpingitis rarely, if ever, demanded laparotomy.

But in the other two affections there was a real tumor. If the fluid could be made to discharge into the uterus, there was no necessity for immediate laparotomy. But if local treatment did not cause diminution of the tumor, and there appeared to be danger in allowing it to remain longer, it should be removed. In pent-up purulent accumulations within the tubes there should be no hesitation in operating. The question of the propriety of tapping the tubes and treating them in the manner suggested by Dr. Polk after opening the abdomen, had not yet been decided upon. In his own experience the tendency in undoubted pyo-salpinx had been to progress from bad to worse.

Case of Pyo-salpinx, with Spontaneous Recovery.—Dr. Ralph Waldo related a case of pyo-salpinx in which the pus discharged a number of times into the uterus, the woman finally recovering from her symptoms and the tumor without an operation. He had also known a number of cases of salpingitis, due to gonorrhœa, recover without an operation.

Dr. Talbot related a somewhat similar case.

Afternoon Session.

World's Fair Committee.—Dr. Morris J. Lewis sent a resolution, read by the secretary, asking the appointment of a committee of nine, to report at the next meeting, on the propriety of holding an International Medical Congress in 1892, under the auspices of the State Medical Society.

The resolution was referred to the following committee of five: Drs. M. J. Lewis, A. M. Phelps, W. B. Chase, Eugene Beach, and A. Vanderveer.

Nominating Committee.—First District, C. C. Rice; Second District, Thomas S. Dawes; Third District, Herman Bendell; Fourth District, A. W. Suiter; Fifth District, H. H. Dean; Sixth District, W. W. Crandall; Eighth District, M .S. Mallory; Member at Large, B. F. Sherman.

Treasurer's Report. — Dr. Porter read his report, which showed a balance in the treasury of $390.84.

Acute Dacryocystitis.—Dr. David Webster said his reason for reading a paper on the subject of dacryocystitis, or inflammation of the lachrymal sac, was the fact that a considerable number of cases entered the hospital which the general practitioner had mistaken for facial erysipelas. But in dacryocystitis the principal swelling and tenderness was immediately over the site of the lachrymal sac; in facial erysipelas there was no more swelling here than over the rest of the inflamed surface. There was greater fever and prostration, though perhaps less pain, in erysipelas. In dacryocystitis there was likely to be a history of "running over of tears." The treatment was by opening the pus-sac between the caruncle and inner canthus. Afterward bathe frequently in hot water.

Prompt Recognition and Treatment of Syphilis of the Brain.—Dr. J. Leonard Corning read a paper with this title. He said that syphilitic affections of the nervous system were infinitely more susceptible to treatment early than later on. Hence the necessity for early diagnosis and treatment. Persistent violent headache was a chief symptom of early syphilis. Many patients complained very early of vertigo, sensory or motor derangement, derangement of sight or speech. Sometimes spasms began in one group of muscles, and might become converted into general convulsions.

Dr. David Webster said usually the condition of the eye due to syphilis of the brain consisted of optic neuritis and paralysis of the ocular muscles, but recently he had seen one case of paralysis of the sphincter iridis in consultation with Dr. Corning. The symptom disappeared under large doses of iodide of potassium.

Spectroscopic Examination of the Blood in Certain Eye Diseases.—Dr. Lucian Howe, of Buffalo, read a paper and demonstrated the use of a modified Hénocque spectroscope by which the blood could be easily examined, showing the amount of hæmoglobin contained and its bearing upon certain affections of the eyes. He thought it could be demonstrated that the condition called by the Germans scrofulous or phlyctenular conjunctivitis was dependent upon anæmia. The treatment should be directed accordingly.

Cataract.—Dr. Francis Volk in this paper gave the results of twenty cases, demonstrating the value of his speedy methods of giving exit to the lens in cataract operations, which he began the use of over two years ago.

It prevented prolapse of the iris at the time of the operation and made extraction easy. The results compared favorably with those obtained from other methods. The special instrument employed he called the iris retractor. It involved no special dangers, and among other advantages lessened risk of prolapse of the vitreous.

Dr. Lucian Howe objected to the method, on the ground that no instrument should be introduced into the eye unless quite necessary.

A Case of Encephalocele Resembling Degeneration of the Lachrymal Sac, read by Dr. William F. Mittendorf, will appear in a future issue.

Treatment of Eczema in Elderly People.—Dr. L. D. Bulkley read this paper. Eczema presented special features according to the age at which it made its appearance. Very commonly, however, it was due to anæmia, whether it occurred before puberty, in those of middle age, or in elderly people. This statement was particularly true in the last-named class of patients. There was likely to be imperfect bowel and kidney action. Most of these cases showed the disease only in later life. Tonics were indicated. The bowels should move regularly once a day.

When diuretics were called for he preferred acetate of potassium to the citrate. Arsenic was seldom valuable. Alcoholics had usually better not be given. Local applications were useful, but the general measures referred to must be carried out.

Dr. Sherwell, of Brooklyn, Dr. Curtis, of Albany, and Dr. Fox, of New York, made remarks on the necessity of taking into consideration the condition of the general system and that of special functions in treating eczema in elderly people.

An Original, Simple, and Effective Method of Treating Scabies.—Dr. Samuel Sherwell, of Brooklyn, described his method of treating scabies, which consisted in the use of sulphur in a different manner from that in which it was commonly employed. The patient was directed to rub without violence dry precipitated sulphur where the lesions were most manifest once a day, preferably at night, sprinkle a small amount of the same powder on the bed sheet; take a simple bath with soap and water twice or three times a week, making at the same time total change of clothing.

Sulphur used in this way was not disagreeable, as were ointments, etc.

A Diagnostic Point.—In cleanly people one was most likely to find excoriations from scratching in men on the

dorsum of the penis, back of the glans; in women, below the nipple and where the corset made pressure.

Evening Session.

The Thomas Hip-splint.—Dr. John Ridlon, of New York, exhibited and described this splint. It was claimed for it that it was simple, easy of construction, inexpensive, easily applied, not readily broken; being a posterior splint, it gave better fixation, if possible, than the lateral or anterior splints; that it left the minimum of deformity.

Immobilization Necessary.—To prevent inflammation, suppuration, and anchylosis, it was desirable to perfectly immobilize the joint.

The Question of what Produces and what Prevents Anchylosis of the Joints.—Dr. A. M. Phelps related in this paper some experiments with immobilization of limbs in dogs. He also gave some statistics of results of treatment of joint affections, some by the method of motion and others by immobilization. His conclusions were that a normal joint would not become anchylosed by simple immobilization for five months; that motion was not necessary to preserve the joint normally; that anchylosis during treatment of diseased joints was not due to prolonged rest, but to pathological causes; that if in immobilizing a joint intra-articular pressure was produced, disease of the head would result; that atrophy of the muscles would follow prolonged immobilization. He therefore advocated fixation in the treatment of inflamed joints, and overcoming intra-articular pressure.

A Case of Tubercular Lesions throughout the Intestinal Tract not Recognized during Life.—Dr. V. P. Gibney read the history of the case of a boy, about twelve years of age, who was in the hospital eight months for joint disease. He finally died, rather suddenly, of miliary tubercles of the lungs. The autopsy showed marked tubercular lesions throughout the intestines, notwithstanding the fact that there had been no symptoms whatever pointing to such lesions during life.

The lengthy discussion which took place on these three papers revealed some difference of opinion regarding the best instrument for use in obtaining fixation of the inflamed joint, for nearly all the gentlemen were opposed to treatment permitting of motion.

Fifty Cases of Fracture of Elbow.—Dr. Charles A. Powers, of New York, recited experience, with treatment, of fifty cases of fracture of the elbow-joint, in which absolute immobilization was carried out from three to seven weeks, active motion alone being practised subsequently. All the patients recovered, with a useful, non-anchylosed joint.

The Pendent Limb in the Treatment of Joint Diseases of the Lower Extremity.—Dr. A. B. Judson called attention to the anatomical features of the pelvic bones, which make the perineal region a better place for the application of a mechanical support than the axillary region, where the brachial and axillary vessels and nerves make the use of crutches painful and awkward. For cases of long-standing joint disease of the lower extremity he advocated the use of the ischiatic crutch, with a high sole under the well foot. He exhibited an inexpensive *sabot*, designed to take the place of the cork sole commonly worn on the well foot in the orthopedic treatment of joint diseases of the lower extremity.

Statistical Paper on Club-foot.—Dr. W. R. Townsend, of New York, read a statistical paper on "Club-foot." It contained an analysis of 2,386 cases seen at the Hospital for Ruptured and Crippled, New York, during the past nineteen years. Of this number 915 were corgenital and 1,471 non-congenital. Of the congenital, 567 were males and 348 females. Of the non-congenital, 744 were males and 727 females. Of both classes 1,311 were males and 1,075 females.

He also presented tables showing the frequency with which the deformity was found in maternity hospitals, as compared with all the births and with other congenital deformities, and showed the proportion of all cases to other deformities as met with in orthopedic hospitals. In congenital club-foot the most frequent form was equino-varus, and both feet were more frequently affected than one and the right more often than the left. The next most frequent forms were varus, valgus, and equinus, the rarest being calcaneo-varus. About seventy-six per cent. of the congenital cases in males were equino-varus, about sixty-seven per cent. in females. Of the non-congenital forms the paralytic, resulting from polio-myelitis, was most frequent, equino-varus, equinus, and calcaneus being most often met with.

Of 581 cases of flat-foot 283 were males and 298 females, both feet being most frequently affected. Other tables were presented, showing the exact number of each variety. Also, analysis of tables by Duval, Lanelogue, Hagen, Roberts, Detmold, Mutter, etc.

Second Day, Wednesday, February 5th — Morning Session.

Representation from Voluntary Medical Societies.—Dr. Simmons read the report of the Committee on By-laws, in which it was recommended that incorporated voluntary medical societies be entitled to send one delegate to the State Society. The recommendation was adopted.

Report of Committee on Hygiene.—Dr. E. V. Stoddard read the report. It recommended a change in the composition of the health boards of the State; that the unit of territory be changed to the county instead of the town or village.

This suggestion of the committee was opposed by Dr. Louis Balch, secretary of the State Board of Health, and the subject was referred back to the committee that it might confer with the State Board of Health.

The New By laws.—The Society went into committee of the whole, to consider the proposed new By-laws. A number of changes were made in the old By-laws, few of marked importance. A new Finance Committee was established, composed of the president, secretary, and treasurer, to consider matters involving money expenditure.

The proposed change regarding nominations by the Nominating Committee was referred to a special committee to report back at this meeting. The new list of By-laws was otherwise adopted by the Society without material change.

Fever and its Treatment.—Dr. A. L. Loomis read the paper. Fever could be divided chemically into two classes of cases, those of nervous and those of hæmic origin. The question was now being asked whether all fevers were not due to some form of infection. The tissue-changes taking place in fever were formerly regarded as the direct result of high temperature. But recently it had been demonstrated that these changes took place sometimes in connection with low fever.

Effect of Fever on the Nervous System.—The dangerous effects on the nervous system had been overestimated, although it had been determined that there was a point at which increase of the bodily temperature caused collapse and even speedy death. This temperature, however, was seldom reached in fevers.

Fever a Complex Process.—Fever, he said, was a complex process in which high temperature was not the most important factor. Those who believed fever in itself was injurious would make freer use of antipyretics than those who took the opposite view. If high temperature was readily reduced by antipyretics, and the patient be rendered more comfortable, they could be employed with advantage. But if powerful antipyretic measures alone reduced the temperature, and had a temporary effect, their use being followed by great nervous depression, they should be omitted.

Two Divisions of Antipyretics.—Antipyretics were di-

vided into two classes, the first being the application of cold, the second being drugs administered internally. The latter most in use at present were antifebrin, antipyrin, and phenacetin.

Cold applied to the body was an important nervous sedative, and played an important part in controlling tissue-changes observed in fevers. He regarded this action as of greater importance than simple reduction of the temperature. But its routine use in any disease was to be deprecated. It should never be employed simply to reduce the temperature unless this passed the danger-point—say 104° F. In typhoid fever he applied the cold coil over the abdomen.

Internal antipyretics were divided into two classes: those which influenced primarily the thermogenic nerve-centres, and those which rendered inert the pyrogenic substances which entered the blood. Heroic doses were objectionable. Treat the patient, not the disease, he said.

Functional Albuminuria, with Three Years' Observation of a Case.—Dr. Eli H. Long, of Buffalo, read the history of the case.

Isolation of Consumptives.—Dr. P. H. Kretzschmar, of Brooklyn, in this paper made some criticisms upon certain measures which had been proposed in isolating the phthisical, in order to prevent spread of the disease, showing their inefficiency and undue severity. He was glad, however, to see a disposition in France to adopt the view that consumptives found greatest probabilities for a cure within sanitaria and not in so-called open health-resorts. But the great danger of the spread of the disease was through the sputum which became dry and floated in the atmosphere.

A Sputum-flask.—He therefore took pleasure in exhibiting and endorsing the blue flask invented by Detweiler, of Germany, for use by consumptives, to be carried in the pocket.

Dr. W. P. Northrup thought Trudo's flask better than the one presented, since the paper containing the sputa could be burned.

Dr. Evans advocated prophylactic measures, overcoming, if possible, constitutional predisposition.

Dr. W. P. Northrup read a paper on "Disinfection of the Clothing of the Physician and Patient in Infectious Diseases," which will appear in full in a future number of the Medical Record.

Coincident Geographical Distribution of Tuberculosis and Dairy Cattle.—Dr. E. F. Brush, of Mount Vernon, in this paper showed that tuberculosis coincided with the distribution of dairy cattle throughout the world, and drew the inference that it was through cattle that the disease was perpetuated in man, and that if a people ceased to raise cattle for dairy purposes it would in time disappear.

Afternoon Session.

Relating to Membership.—On motion of Dr. Roosa a resolution was passed granting all the privileges of active members to such permanent members as had paid into the treasury in the form of dues fifty dollars.

Address on Surgery.—Dr. Alfred Mercer, of Syracuse, vice-president of the Society, read the address. Since he began practice anæsthetics had been introduced, and he pictured the difficulties under which surgeons performed amputations and other major operations at that time.

Antiseptics or Cleanliness.—He also traced the progress of antiseptics in surgery, and said we had arrived at the time when the profession was divided in opinion on the question whether the advantages of methods of treating wounds to-day over methods which prevailed before Lister came on the field were due to antiseptics or to rigid cleanliness? Treatment by antiseptics and by simple but strict cleanliness both gave statistics equally gratifying; but, by the former method, care should be taken not to use an amount of poisonous drug to do injury.

Some of the antiseptic methods had rightly been discarded as useless, if not positively harmful.

History of 255 Cases of Excision of the Superior Maxilla.—Dr. J. D. Bryant, of New York, read the paper. Of these cases only two occurred in his own practice.

Conclusions.—1, Excision of the superior maxilla is not a dangerous operation; 2, that, contrary to general belief, excision of both maxillæ is not a specially dangerous operation; 3, that while severe hemorrhage is not frequent, still its effects are to be feared more than any other result of the operation; 4, removal of the upper jaw for cure of bony and fibrous tumors, or removal of naso-pharyngeal polypi, is followed frequently by severe and even fatal hemorrhage; 5, that ligation of one or both external carotids is a safe and commendable procedure when severe hemorrhage is apprehended as a result of operations on the area of their distribution; 6, that ligature of one or both of these arteries may delay the return, or hinder the development of the morbid growth; 7, that, all things being equal, ligation of the common carotid for the purpose of controlling the circulation of the external, is unwise and unwarranted.

Report of the Committee on the President's Address.—Dr. Potter, Chairman of the Committee, read the report. They reported favorably on the recommendations contained in the address, and they were adopted in resolutions, except that part relating to making presidents of the county societies *ex-officio* members of the State Society.

It was deemed advisable that action be postponed on this recommendation until another year. The resolutions included the bill adopted by the Society last year, providing for a State Board of Medical Examiners, and now awaiting action by the Legislature.

Diagnosis and Treatment of Fractures through the Anatomical Neck of the Humerus.—Dr. Charles A. Powers, of New York, in this paper refuted the general teaching of the books that this was a rare location for fracture, and that the diagnosis was very difficult. Moreover, his cases disproved the assertion that bony union rarely resulted. Between 1878 and 1888 there had been eighty-two cases recorded in the dispensary of the New York Hospital. The diagnosis in these cases was confirmed by two or more skilled surgeons. It was shown by crepitus, by rotation of the greater tuberosity unaccompanied by rotation of the head of the humerus. There was also swelling, sometimes ecchymosis and tenderness.

Treatment.—This was simple, and secured complete confinement. This was best done by a plaster-of-Paris splint, worn four to seven weeks. Ultimate complete, or nearly complete restoration of function could be expected.

Reflections upon some Cases of Nephro-lithotomy.—Dr. E. L. Keyes read this paper, which is reported in full on p. 141.

Report of Five Cases of Supra-pubic Cystotomy for Tumors of the Bladder and Vesical Calculi.—Dr. A Vanderveer, of Albany, sent the paper, which was read by Dr. Hailes. The first case was for removal of a papillomatous growth, supra-pubic cystotomy proving a much more satisfactory exploratory operation than the perineal operation, which he had done previously on this patient

This method he thought much the most satisfactory in the other four cases also—one of tuberculous ulcers in the bladder, two of sacculated stone.

A Rarely Described but Common Form of Cystitis in Women.—Dr. Robert T. Morris, of New York, described a cystitis in women due to an excoriation and fissure of the sphincter of the bladder, a condition more common than fissure of the anus. It caused tenesmus

and great inconvenience. Treatment was by dilatation with the little finger, cocaine if necessary, the use of the scalpel introduced between the blades of a speculum, and catgut suture. In one case he had performed supra-pubic cystotomy. The bladder was washed with boro-glyceride. one ounce, and glycerine, three ounces, mixed. Another important measure was vaginal support by wool tampon. Pepsin digested mucus and blood-clots within the bladder.

Extension Splint for Treatment of Fractures of the Leg, Arm, and Forearm.—Dr. P. R. Furbeck, of Gloversville, presented a light extension splint for this purpose, made of metal. With it was used the weight and pulley, to overcome spasm of the muscles.

Operative Treatment of Erysipelas. — Dr. Willy Myer, of New York, described several cases of erysipelas, spreading from wounds, which he had cured, preventing the spread of the disease by the method, more generally employed in Germany, of making numerous cross-incisions into the surrounding healthy skin deep enough simply to draw blood. The patient was placed under ether. He thought it was the duty of the physician to employ this method in all cases, particularly of a threatening character.

Dr. S. A. Fox, of Brooklyn, had, when in Charity Hospital, seen one or two hundred cases of erysipelas, sent there from other institutions, which they treated by the old-time method of lead and opium wash locally, iron and quinine internally, and milk diet. He did not remember a single death.

Drs. A. Jacobi and R. T. Morris thought the scarification method deserving trial.

Evening Session.

The Anniversary Address.—In his anniversary address Dr. Daniel Lewis treated mainly of the relations existing between the profession and the public, but in doing so had much to say of subjects also of particular interest to the profession.

Medicine not an Inexact Science.—In the many discussions regarding the proper place of medicine among applied sciences, both physicians and laymen yet characterized it as an inexact science. There were many reasons, which he cited, showing that designation to be unjust. This was certainly true if we accepted the definition of science as "knowledge duly arranged and referred to general rules and principles on which it is founded." Astronomy, navigation, etc., were little more exact sciences than medicine. One of our chief aims should be to secure proper recognition of the scientific exactness which formed to-day the basis for all successful applications of the healing art.

Radical Defects in Medical Education.—In this connection the importance of preliminary general education was emphasized.

Sectarianism.—There was no longer any reason for the existence of sectarian schools of medicine. Every medical school should teach everything of value in any other school.

There was a homœopathic school in New York which taught every form of materia medica or therapeutics practised by any school. If that school would drop its sectarian name it would become more nearly the model school than any other college in the State. There could be no real antagonism in science.

State Medical Examining Board.—One chief necessity for this was to control foreigners practising in the State, not a few of whom had not a knowledge of the English language. Objections to such a board were shown not to be well founded.

Relations of the Profession to the Laity.—These were not what they should be in all respects, and some suggestions for rendering those relations more harmonious were made.

Third Day, Thursday, February 6th—Morning Session.

Report of Committee on Legislation.—Dr. Roosa read the report, which related chiefly to matters already known to the profession concerning the Board of State Medical Examiners, etc. In the event that the bill before the Legislature could not be passed in its present form, the Committee was authorized to accept a change, leaving the appointing of the members of the Examining Board to the Regents of the University.

Method of Electing Officers.—After considerable discussion it was voted to let the old by-law remain.

Nominations.—The Committee presented two names for President, W. W. Potter, and Lucian Howe, of Buffalo; also two names for Vice-President, Drs. Pilcher and G. R. Fowler, of Brooklyn. Dr. Fowler telegraphed withdrawing his name. Dr. Potter received forty-three of the sixty votes cast and was declared elected *President*. Dr. Curtis was re-elected *Secretary*, and Dr. Porter *Treasurer*. *Committee on By-laws* — Drs. Laurence Johnson, A. R. Timmons, and H. C. Curtis. *Committee on Hygiene* — Drs. E. V. Stoddard, A. N. Bell, C.W. Hamlin, J. P. Creveling, W. H. Baily, W. C. Baily, and E. F. Brush. *Committee on Legislation* — Drs. D. B. St. John Roosa, Daniel Lewis, and M. J. Lewis. *Committee on Ethics*—Drs. A. Jacobi, A. Matthews, and H. R. Hopkins. *Committee on Prize Essays* — Drs. G. F. Shrady, Daniel Lewis, and Eugene Beach. *Committee on Arrangements*—Drs. S. B. Ward, E. L. Partridge, and E. S. Merrill. *Committee on Publication*—Drs. F. C. Curtis, Charles Cary, O. B. Douglas, and C. H. Porter. *Honorary Members*—Drs. George J. Engelmann, of St. Louis, and R. J. Levis of Philadelphia. *Eligible to Honorary Membership*—Drs. W. H. Hingston, of Montreal, and H. C. Wood, of Philadelphia.

A number of delegates were elected to State and other societies.

Vaccination Bill.—The Society, on motion of Dr. Balch, endorsed the bill before the Legislature, to prevent the spread of small-pox during epidemics.

Dr. S. D. Powell read an interesting paper on "The Treatment of Diseases of the Rectum, based upon Anatomical Study."

Other papers on the programme were read by title.

After the passage of the usual resolutions of thanks the Society adjourned.

The Angle of the Neck of the Femur.—In text-books on human anatomy we are taught that the angle formed by the neck of the femur with the shaft becomes lessened as years advance, the level of the head of the bone being consequently lowered. Professor Humphrey has shown that this theory is inaccurate. After careful observations, recorded in the *Journal of Anatomy and Physiology*, he has come to the conclusion that the angle formed by the neck of the thigh-bone with the shaft varies considerably in different persons at any given period of life. It is smaller in short than in long bones, and it is also most likely to be small when the pelvis is wide; the combination of these two conditions rendering it usually smaller in women than in men. The angle decreases during the period of growth, but after growth has been completed it does not usually undergo any change, even if life be continued to extreme old age. Some change may take place in exceptional cases, but, as a rule, the angle remains the same from the adult period till death, at whatever age death may occur. If, during the growth, the limb be relieved of the weight of the body, as in the bedridden state, in paralysis, or in a stump, the angle of the neck with the shaft usually retains the open form of early life, or may even become wider. Professor Humphrey's conclusions will interest the surgeon, and must never be overlooked in cases where the age of a subject at death has to be estimated by examination of the thigh-bone.—*British Medical Journal.*

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, January 27, 1890.

ALEXANDER S. HUNTER, M.D., PRESIDENT, IN THE CHAIR.

Relations of Maldigestion to Functional Nervous Diseases.—DR. WILLIAM H. THOMSON read the paper. He said that as a teacher of materia medica he had long been in the habit of dividing medicines into two great classes, namely, the organic and the functional, the former being those whose special remedial action could never be secured by one dose, but by the accumulated effects of many doses, as bichloride of mercury in syphilis; the latter being those whose entire specific action could be obtained by one dose, as opium. Organic medicines were given for organic disease, and produced no symptoms of their own; functional medicines did nothing but produce symptoms. Organic medicines showed no effects except in disease; functional medicines produced the same effects in health as in disease.

Neurotics do not Cure.—Neurotics belonged to the functional medicines, relieving symptoms but not curing the disease. Structural changes in an organ produced corresponding functional derangement, but the converse did not necessarily follow, that functional derangements must always have their corresponding structural change.

Distinction between an Organ and its Function.—This became apparent when the difference between an organ and its function was clearly apprehended. One could stimulate or retard the working of an organ, as of the lungs, without affecting its structure. The human body might, in this respect, be compared to a steam-engine or a lamp. The function of a lamp was to give off light. This function would be materially modified according to whether the lamp were fed with pure or contaminated oil, although its structure remained unchanged. Thus one could see the error of those who looked forward to the time when the term "functional," as applied to human ailments, should be banished, and a name be given based on the anatomical changes which they hoped would in all cases be discovered.

The Practical Aspect of the Question.—If every functional nervous disease was due to a distinct morbid change in nerve-cell or fibre, then we must continue to search in the nerve-cell or fibre for that change and for its causation, and be guided in the treatment accordingly. If, on the other hand, some of these functional nervous disorders were unattended by alteration in the nervous structure, as a poor light might result from bad oil in a good lamp, then we must look elsewhere for the cause and remedy.

Symptoms Distinguishing Functional from Organic Nervous Diseases.—The symptoms of no structural organic nervous disease were ever truly intermittent. For instance, the hemiplegic might show a greater degree of weakness one day than another, but he was hemiplegic nevertheless. Not so with functional nervous diseases. The most skilled specialist might not be able to tell that a given woman was accustomed to having convulsions, or that a vivacious lady would be prostrated with a headache next day. One was no more likely to find a structural change to account for these facts than to find the structural anatomy of cupidity or benevolence. A truly intermittent disease could have no organic basis in the nervous system. Functional nervous diseases, including epilepsy, were due to afferent impressions. If a tumor within the skull caused epilepsy, it was by an afferent impression, as much as if the afferent impression came from the presence of a tape-worm in the intestine. If the disease manifestations were not intermittent, the presumption was that the case was one of organic disease.

Seeking a Toxic Cause.—Affirming that there were purely functional nervous disorders, without any organic change in the nerves, sufficient even to sometimes prove fatal, what, he asked, were their causes? One direction to which he called attention was that of toxic agents developed within the system—a chemical cause. An example was given in which the chief improvement in the patient's condition resulted from diet. The author went on to quote from different chemists and physiologists, proving the development of toxic agents in the intestine, urine, etc., agents which produced effects like those of morphine, quinine, etc. Many of them were capable of causing headache, muscular languor, depression of the heart, great depression of spirits, lowering of the temperature, and convulsions. Usually we were protected from self-poisoning through the function of the liver, and among the most efficient antiseptics were the digestive juices of the alimentary tract. This double function of the digestive juices was too often overlooked in combating disease. Derangement of the stomach and bowels, of a direct or reflex nature, he thought, preceded the development of the hysterical status in the majority of cases. He had had better success in the treatment of hysteria by medication directed to the alimentary canal for the prevention of toxæmia than he had ever before obtained from the use of old-fashioned antispasmodics. The same was true, in the main, of migraine. The same principle applied largely to the treatment of epilepsy, but he reserved the elaboration of this idea for a future occasion.

Charmed by Eloquence.—DR. A. JACOBI, being requested to open the discussion, said he was so much under the influence of Dr. Thomson's varied knowledge and eloquence that he found it difficult to discuss his paper or object to his conclusions. It had frequently taken him a few minutes to convince himself that this gentleman was wrong in a number of positions he had assumed. He had not the slightest doubt that he was wrong on many points to-night. For instance, he had made a positive distinction between functional and organic diseases, and it must be admitted that a number of his examples were exceedingly well chosen and not easy to disprove. But a large number of symptoms once recognized as functional diseases had subsequently been found to be due to organic changes, and it might prove so of some of the diseases which Dr. Thomson now regarded as purely functional.

Epilepsy an Organic Disease.—Epilepsy, he thought, was an organic disease; the lesion had been shown in many cases, and the very fact that the attacks returned from time to time made it sure, in his opinion, that there was a change in the nerves. Anæmia of the brain would produce an epileptic attack, the change in the circulation being the proximate cause, while the original, remote cause might be unknown.

Functional and Organic Medicines.—Such a division of medicines might be convenient in lecturing to students, but was, he thought, more or less arbitrary. Arsenic, it had been claimed, gave rise to tangible changes, while opium did not. But, he asked, what caused morphinism if tangible effects were not produced? Digitalis, by increasing the circulation in general, and of the heart in particular, changed the nutrition and produced tangible effects in the heart muscle.

Bismarck's Gout and the World's History.—He said the reader of the paper had viewed the relation between functional nervous diseases and maldigestion chiefly from the nervous side. Viewed from the side of maldigestion, many headaches and mental disturbances could be accounted for in this manner. Who did not know of the value of an aperient in relieving congestion of the brain? Much of modern history made by a great statesman depended upon his whims and emotional changes arising from maldigestion and a gouty constitution. The vessels of the brain not being surrounded by muscles to aid the circulation, that organ was most likely to suffer under maldigestion, malnutrition, and malelimination.

Another Classification.—DR. C. L. DANA thought the time would come when the term functional nervous disease would be dispensed with, and a division be made into or-

ganic and degenerative affections, a few cases, perhaps, being left under such terms as toxic, hyperæmic, etc. Under degenerative he would include such affections as epilepsy, paralysis agitans, given types of hysteria, some forms of tic, and spasmodic and mental disorders which approached insanity. By using the term degenerative we avoided the inference that the disease had no organic basis. There was, perhaps, want of nutritional power, or lack of full development of the cells which controlled or regulated the function.

The Toxic Element.—The toxic element would probably be shown to play an important rôle in the causation of the degenerative diseases, but practically he had not found treatment based on this view of much value in any considerable number of cases of epilepsy, neurasthenia, etc. In one case, however, of *petit mal* and *haut mal*, in a boy, with frequent recurrence of the attacks, nothing was done but enforce a rigid diet, and for three months the boy had been without an attack.

Neurasthenia.—Severe cases of these nervous troubles were more likely to yield to treatment based on the autotoxic theory in the middle-aged rather than in young or elderly subjects.

Dr. J. L. Corning endorsed the views of the author that there were many functional nervous disorders in which we could find no organic basis, and in which the chemical cause seemed to be the true one. But regarding the means of antagonizing those causes we as yet knew little. We did know this, however, that treatment based on physiological principles gave the best results. It included diet, sleep, exercise, change of climate, etc.

Influence of the Sympathetic System.—Dr. George W. Jacoby thought the chemical theory only partly explained the cases under discussion. In some the mental state preceded the maldigestion, and the influence he believed was exerted by way of the sympathetic system. He tried first to determine whether the cause was originally in the stomach or in the central nervous system, and was guided in his treatment accordingly. When the former was the case he had found that pressure over the solar plexus nearly always caused pain.

Dr. M. Putnam-Jacobi remarked, as possibly throwing some light on this subject, that a functional change sometimes took place in an organ or nerve-centre distant from the organic lesion. A tumor in the brain, for instance, might be the cause of sudden death by arrest of function in the respiratory or cardiac centres, although the tumor had no immediate connection with those centres.

Physical Changes Attend all Physiological Action.—This fact had also been demonstrated, and showed the necessity for attention to disassimilation as well as assimilation, and the necessity for sweeping out the fatigue products.

Dr. Grace Peckham thought that Dr. Thomson, starting in the circle in one place, had interestingly shown the relation of maldigestion to functional nervous diseases. Beginning at another place, one might show the relation of functional nervous diseases to maldigestion. He had found benefit from medicines directed against maldigestion. She, on the other hand, had found in the other class of cases, or those of mixed or unknown nature, that medicines directed to the nervous system gave good results.

Dr. Thomson closed the discussion, showing wherein there was real or only apparent disagreement between himself and the speakers.

Atropine in Paralysis Agitans.—Dr. Moretti, of Rome, read a paper recently before the Lancisi Society, in which he reported some excellent results from the use of atropine in the treatment of paralysis agitans. One of his patients was the painter Vertunni, who had been obliged to abandon his occupation, but had improved so greatly under the use of this drug that he was able to go back again to his painting.

OUR LONDON LETTER.

(From our Special Correspondent.

FOUR HUNDRED AND NINETY CASES OF PNEUMONIA—OSTEOCHONDROMA OF THE HUMERUS TREATED BY REMOVAL OF UPPER EXTREMITY, TOGETHER WITH SCAPULA AND PART OF THE CLAVICLE—THE MECHANISM OF SUSPENSION IN LOCOMOTOR ATAXY—THE INFLUENZA EPIDEMIC—THE NATIONAL LEPROSY FUND.

London, January 18, 1890.

At the Medical Society of London, on Monday last, Dr. Churton, of Leeds, read a paper on pneumonia based upon a study of 490 cases; of this number, 273 were men, 106 women, and 111 children under fifteen. So far as could be made out under the microscope, the alveolar walls were affected to but a slight extent, even in the acute affection, and he attributed the exudation of the fibrinous material to interference with the epithelium, which, under normal circumstances, prevented its taking place. He emphasized the simplicity of the discoverable anatomical facts of pneumonia. The morbid conditions which gave rise to pneumonia were also capable of giving rise to pleurisy, pericarditis, etc. He thought it probable that a drug or method of treatment might hereafter be found which would (in the early stages at least) do for the pneumonic exudation, and for the tissues, what the salicylates now did for the rheumatic exudation and the tissues permitting it. A short discussion followed the reading of Dr. Churton's paper. The President (Dr. Theodore Williams) expressed his conversion to the belief that pneumonia was a blood and not a lung disease, resembling in its course the zymotic diseases. He had often examined the sputum for the micrococcus, but with only limited success. He remarked that in their endeavor to ward off cardiac failure, practitioners were very apt to overstimulate the heart so as positively to depress it. Dr. Maguire said that in addition to the ordinary division of pneumonic cases into croupal and catarrhal, it was necessary to distinguish between the epidemic and sporadic. He had found the micrococcus almost invariably present in the lungs in the epidemic, but only occasionally in the sporadic form; it was not much use searching for it in the sputum, which contained another micrococcus very difficult to distinguish from it. He thought it still doubtful whether the micrococcus was really at the root of the disease.

At the last meeting of the Medical and Chirurgical Society, Mr. Thomas F. Chavasse, of Birmingham, read notes of a case of osteochondroma of the humerus. He had removed the arm *en masse*, the scapula, and also a portion of the clavicle. Secondary hemorrhage occurred on the seventeenth day, and necessitated ligature of the subclavian artery in the second part of its course. The patient recovered and was now living, a year having elapsed since the operation. Mr. Chavasse's removal of the clavicle received some adverse criticism; both Mr. Christopher Heath and Mr. Barwell regarded it as unnecessary. Mr. Hulke could not understand why the scapula had been removed, as there was no clinical evidence of either that bone or the muscles attached to it being implicated. Mr. Chavasse, in replying, contended that removal of a piece of the clavicle was necessary, so as to secure both artery and vein at once, for there was great danger of death from the entrance of air into the veins. The scapula was removed because no skin flap could be obtained without doing so. His original diagnosis of the case was that it was one of an enchondroma which was undergoing some sarcomatous change.

Dr. James Cagney then read a paper on "The Mechanism of Suspension in Locomotor Ataxy." He opposed the assumption that it was possible to stretch the spinal cord or the nerve-roots by suspending the weight of the body from the head or elsewhere, and that such a stretch-

ing (if it were possible) could produce any change in the lesion of tabes. From observations made, both on living and dead bodies, he believed the effect of suspension was to shorten the distance between the first dorsal and last lumbar spines. There was usually an elongation of that surface in the cervical region, which, however, was less than the shortening elsewhere. Measurements on the dead body showed that at the same time the anterior surface of the vertebral column was considerably elongated throughout, slightly in the neck, and most in the dorsal region, but it was contracted or unchanged in the lumbar region. The effect of suspension was to straighten out the curves, and this in a different manner in the different regions. The effect on the cord or its membranes would vary according as they lay in the concavity or on the convexity of a curve, and with the manner in which the curve tended to straighten under the influence of the weight of the body. A distinction must be made between the cord and its membranes. Relaxation of the membranes implied relaxation of the cord, but tension of the former did not necessarily imply stretching of the cord. Dr. Cagney thought the facts cited proved that a total shortening of the spinal canal was obtained in suspension. In the lumbar region the cord was unaffected, or slightly relaxed; in the cervical region the membranes were somewhat stretched. The dorsal region was of chief importance, because the dorsal curve was the most extensive, and because the lesion in tabes was, for the most part, contained in it. Here the cord lay upon the convexity of the curve, and by stretching this post mortem the bodies of the vertebræ were separated anteriorly, their posterior borders were pressed together, while the neural arches and spinous processes were approximated. Since, however, the neural arches enclosed the spinal cord, the latter was also shortened. This effect was produced by gravity, and was further aided by muscular tension during life. Measurements showed that the shortening of the line along the spinous processes was greater in the living than in the dead subject. He inferred that suspension caused a relaxation, not a stretching, of the spinal cord, and that such a relaxation might affect a sclerosis in two ways, viz.: 1, mechanically, by breaking down adhesions; 2, by removing impediment to the circulation. The splanchnics were the only nerve structures which could be seen to stretch in the process, and some of the accidents in cases of suspension were referred to this cause. Dr. Cagney contended that muscular tension was also an effective force, and that a rational method should be based on its application. Suspension from the head was admittedly dangerous and inconvenient; according to his views it was also useless. The best results might be expected from suspension from the axillæ alone, or from suitable gymnastic movements.

The influenza epidemic appears to be abating—in London, at any rate. During its prevalence it has attacked rich and poor alike, and has largely increased the death-rate. Most of the deaths of influenza patients, however, have been due to pneumonia or some other complication.

The Prince of Wales presided at a dinner, on Monday last, in aid of the National Leprosy Fund. Among the speakers were Sir Andrew Clark, Baronet (President of the Royal College of Physicians), the Bishop of London, Mr. Jonathan Hutchinson (President of the Royal College of Surgeons), and the Archbishop of Canterbury. The Honorary Secretary (Sir Somers Vine) announced that the total sum received was seven thousand pounds. It is proposed to found travelling scholarships, should adequate funds be received.

OUR PARIS LETTER.

(From our Special Correspondent.)

THE EPIDEMIC OF INFLUENZA IN PARIS.

PARIS, January 17, 1890.

To the very lucid description given in your editorial in the MEDICAL RECORD of the 4th instant, on the epidemic of influenza as it occurred in New York, the following note, which I have culled from different authorities in Paris, may be added, as it may be of interest to compare your account with that given of the epidemic on this side of the Atlantic. The epidemic of influenza, or "la grippe," as it has been seen in Paris, commenced about the beginning of December last. Like all the previous epidemics, it has passed through two successive periods. In the first, which lasted about fifteen days, the "grippe" reigned alone, generalizing itself with its usual rapidity, emptying the lycées, schools, barracks, and disorganizing the great administrative services, but killing no one, this is said to be the benign phasis. In the second period, following the same rule, pneumonia has complicated the grippe, and the mortality increased suddenly to considerable proportions, this is the phasis of complications. During the first first fortnight, the grippe, disengaged of all accessory elements, was characterized by phenomena which are special to it, viz.: intense aching pains in the loins, sometimes extending all over the body, accompanied with nervous prostration, and fever more or less severe according to the subjects, being particularly severe in children. This condition exists sometimes alone, it is sometimes followed either by gastric troubles or by a rhino-tracheitis. In certain subjects there are produced cutaneous eruptions of a scarlatiniform or rubeolic aspect. These eruptions, which led certain persons to believe that it was the dengue of Syria which invaded Paris simultaneously with the influenza of Russia, have nothing special with the present epidemic. They were noticed in the previous epidemics, and particularly by Recamier in the epidemic of 1803. In the second period pulmonary complications were developed, assuming immediately, as in 1837, an extremely grave character. They present themselves under three principal forms, viz., lobular pneumonia, disseminated or pseudo-lobular broncho-pneumonia, and suffocating catarrh. The municipal weekly report, though very incomplete in some respects, furnishes sufficient elements to appreciate the formidable gravity of these pulmonary affections. The mortality from lobular pneumonia, which in the corresponding week of 1888 was only 67, in the last week of 1889 rose to 346; that from broncho-pneumonia, which in 1888 was only 27, rose to 138. To this may be added 131 deaths from acute bronchitis, 127 from chronic bronchitis, and 140 from congestion and apoplexy of the lungs, making a total of 882 deaths from pulmonary affections, instead of 200, which is the average number in this season. Although the report attributes only 22 deaths to grippe and its sequelæ, it is difficult to believe that the present epidemic has had nothing to do in this formidable augmentation in the mortality from pulmonary maladies.

Acute bronchitis, however acute it may be, and pulmonary apoplexy do not ordinarily pass for fatal affections. Moreover, in generalizing itself, the grippe has struck, like the others, subjects affected with chronic maladies, old persons weakened by age, cardiac and phthisical subjects, etc., and, according to the law established by all classical authors, the patients of this category have succumbed in great numbers. Here again, notwithstanding the defects in the municipal weekly report, in which the cause of death is not indicated in each case, yet, under present circumstances, it has been sufficiently intelligible on this point. For instance, under the head "Senility," there are 73 deaths, instead of 28 for the corresponding week of 1888. Under hemiplegics, there were 81 deaths, instead of 56. The number of cardiacs has been doubled, 123 instead of 65. The same as regards phthisical subjects, from 180 to 200 (the weekly average) the mortality has risen to 421. In fine, the total mortality from all causes for the last week of December amounted to 2,334. It may be remarked that of this total the cause of death was not indicated for 430 cases. There were 3,784 deaths during the month of December, 1888, and 5,969 for the month of December, 1889. The number in excess in the mortality since the

commencement of the epidemic of influenza is therefore more than 2,000. The total of deaths for the first week of the present year is given as 2,683, and during the second week the epidemic will have reached its highest point, as previous epidemics of this affection have ordinarily lasted from six weeks to two months. The present epidemic has manifested itself under three different forms: 1. The nervous form, which sets in suddenly by complete prostration, a high fever, which rises to 101° F. and even 102° F., restlessness, and sometimes a tendency to attacks of syncope. After twenty-four hours all the symptoms subside and a copious perspiration marks the end of the attack. 2. The catarrhal form, which does not commence so suddenly. There is a period of incubation which lasts two days, then the temperature rises by degrees, and fits of coughing are the principal symptom. After forty-eight hours the general state of the patient becomes improved and the fever gradually subsides. 3. The gastric form, which is characterized principally by troubles of digestion. The duration of this form is equal to that of the two others. The treatment generally adopted has been more or less symptomatic, or in accordance with indications, and has consequently been varied. Many drugs have been vaunted as specifics, but they were not long in favor. Even antipyrine was set aside, and the time-honored remedies, such as quinine, ipecacuanha, and opium, were more generally adopted, with some success.

WHOLESALE PRESCRIBING OF MANUFACTURED MEDICINES.

To the Editor of the Medical Record.

Sir: Allow me, through the columns of your paper, to call attention to the wholesale prescribing of manufactured medicines—I do not now refer to patent medicines, of which so much has been said—which, undoubtedly, is growing throughout the profession. Go into any drug store and see the large stock of manufactured medicines they are carrying; drawers upon drawers contain pills, tablets, granules, etc., and hardly a day passes that the stock is not increased. Dr. So-and-so, orders so many pills of X. & X.'s, if the druggist has not got them he sends for them, which, necessarily, causes a delay to the patient; and the druggist, after giving out the desired number, puts the remainder away, and it may be months—yes, years—before he ever has a call for them again; and if that order comes years after, does he get a fresh supply? Why, of course not. Is he going to expend money for something he already has in stock? and if the drug has lost its physiological action so much is added to the misfortune of the patient.

I have seen prescriptions that called for quinine sulphate, or podophyllin, or cerium oxalate, and the druggist instead of compounding the same—as the doctor prescribing it expected—would go to the drawer and take some manufactured pill and give to the messenger waiting. Only a few days ago I saw a lady enter a well-known drug store, and after looking intently at a paper which she held, inquired of the clerk in attendance: "Have you any of X. & X.'s morphine and salol pills?" and, as the clerk was getting them for her, she returned the paper—which was a prescription—to her pocket, where it would remain until wanted again. On another occasion a young man came in and asked for a well-known tonic pill, at the same time reading the ingredients of it from the prescription he held in his hand.

I have asked a number of druggists if they had many such cases, and every one has given me the same answer: "Yes."

I have in my mind a case of an eminent doctor, here in this city, who sent to any number of shops endeavoring to get a certain "dyspepsia tablet," manufactured by a firm miles from New York. True, he could have made out a prescription himself containing the identical ingredients, but no, nothing would do, he must have that firm's tablets. The evil of all this can readily be appreciated; the blame lies principally at the physician's door—though the druggist is not without blame—and there is the place where reformation must commence.

One can hardly understand how a man who has had a good scholarly education, followed by a degree from a first-class medical college, can have so little knowledge of Latin; but such, nevertheless, is a well-demonstrated fact, and only too well known. But now that our colleges are recognizing the benefit of a primary, or entrance, examination, we may hope that hereafter a man who obtains his degree, will go out in the world clothed with a certain amount of the "dead language," and that he may be able to write prescriptions from his brain, and not resort "as a cloak for ignorance," or laziness, to this wholesale prescribing of manufactured medicines.

Yours very truly,

Harry Mortimer Archer, M.D.

14 West Fifty-second Street, New York

VAPOR OF BROMINE IN DIPHTHERIA.

To the Editor of the Medical Record.

Sir: Dr. Manchester's very sensible article on the use of bromine in diphtheria (Medical Record, January 18, 1890, p. 64) recalls the early history of bromine as a therapeutic agent.

The use of bromine vapor was first suggested to me by the late Dr. Middleton Goldsmith, in September, 1861, on purely theoretical grounds. Subsequently it was largely and very successfully used as a disinfectant in the western hospitals of the army, under Dr. Goldsmith's direction, in conjunction with the local application of bromine and of the solution of bromine, in hospital gangrene and erysipelas. See Goldsmith's "Report on Bromine to Surgeon-General U. S. A." 1863, also "Medical and Surgical History of the War," Part III., Medical Volume, p. 673.

I have used bromine vapor in diphtheria, precisely as advised by Dr. Manchester, since the autumn of 1862, with advantage.

A. P. Meylert, M.D.,

Late Surgeon and Medical Director U.S.A.

Las Vegas Hot Springs, N. M., January 22, 1890.

REVISION OF OUR PHARMACOPŒIA AND UNIFORMITY IN DOSAGE.

To the Editor of the Medical Record.

Sir: Being interested by an article which appeared in the Medical Record of January 11, 1890, by H. H. Rusby, M.D., entitled, "The Physician's Proprietary Articles, or Uniform Preparations for our Pharmacopœia—Which?" I thought a few words bearing on the title of my article would be quite apropos. The thoughts expressed by Dr. Rusby I heartily second, but why would it not be best to go down even farther with the revision than he suggests.

The great disparity in the doses of our different fluid preparations, and the large number of these which are officinal, was brought forcibly to my mind when a student of medicine, and I determined then to propose a scheme to the next revising board whereby we might establish a common dose for all fluid preparations, and lessen the number of these preparations.

The duties of the coming Revising Convention, I think are threefold, viz.:

1. Making a standard strength for all medicines (Dr. Rusby's suggestion).

2. Making a uniform, maximum and minimum dose for all fluid preparations.

3. Throwing out all drugs that have been found "wanting," and cutting down the profuse number of fluid preparations of the same drug.

1. Dr. Rusby has discussed this point so thoroughly

that it is not necessary to say anything more on the subject.

2 and 3. In the first place, they should divide the drugs of the vegetable kingdom into two classes, calling them (*a*) potent remedies, or those which are poisonous in their nature, *e. g.*, aconite, belladonna, opium, nux vomica, etc.; (*b*) non-potent, or those which are mild in their action, *e. g.*, asafœtida, buchu, cinchona, ergot, etc. In the second place, they should abolish all the fluid preparations of the drugs save one, calling it fluidum, as fluidum aconiti, or fluidum ergotæ. Possibly it might be well to retain the vina and the syrupi of the different medicines. Of what practical value is it to have two or more fluid preparations of the same drug, with actions the same, differing only in strength? In this simple way we would cut down our Pharmacopœia, and yet retain all our favorite drugs.

In the third place they should give to the potent remedies a uniform maximum and minimum dose, say from five to ten drops, or minims, and to the non-potent, from thirty to sixty drops, or minims.

Life is too short for the ordinary practitioner to try and remember the doses of the different drugs and poisons, even to be found in "Wood's Pocket Therapeutics and Dose-Book." There are too many other things equally, if not more, important to be remembered. It would seem to me a little embarrassing to be obliged to refer to a dose-book in the presence of your patient, as I have heard of some men doing; and yet you might be doing him an untold wrong by not prescribing a certain drug when indicated, simply because you were not sure of its dose.

I would like to advise the physicians and pharmacists to think of this matter before it is too late, and if a plan which is more feasible is suggested, give it to the profession through some medical journal.

C. K. Fleming, M.D.

1616 Glenarm Street, Denver, Col.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from January 26 to February 1, 1890.

Macauley, C. N. Berkeley, Captain and Assistant Surgeon. By direction of the Secretary of War, the extension of leave of absence granted in S. O. 294, December 18, 1889, A. G. O., is farther extended one month. S. O. 22, Par. 1, A. G. O., January 27, 1890.

Middleton, Johnson V. D., Major and Surgeon. Granted leave of absence for fifteen days. Par. 9, S. O. 27, Headquarters of the Army, A. G. O., January 25, 1890.

Official List of Changes in the Medical Corps of the United States Navy for the week ending February 1, 1890.

Rush, C. W., Passed Assistant Surgeon. Detached from Naval Academy, and placed on waiting orders.

Decker, C. J., Assistant Surgeon. Ordered to the Naval Academy.

Green, E. H., Passed Assistant Surgeon. Detached from the Alert, and placed on waiting orders.

Beardsley, G. S., Medical Inspector. Granted extension of leave to April 30th, with permission to remain abroad.

Constipation and Vomiting of Pregnancy.—An Austrian physician reports a case of obstinate vomiting of pregnancy which was immediately relieved by emptying the bowels by enemata. As long as the bowels acted regularly there was no trouble, but the vomiting returned whenever constipation was present.

Medical Items.

Contagious Diseases.—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending February 1, 1890.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	17	2
Scarlet fever	73	13
Cerebro-spinal meningitis	1	3
Measles	81	10
Diphtheria	112	24
Small-pox	0	0
Varicella	6	0
Cholera	0	0

The Dawson Prizes.—The annual contest for the Dawson prizes at the Good Samaritan Hospital, Cincinnati, was entered by a larger number of aspirants than usual. These contests in bandaging, drawing, and dissecting, are made by the students of the Medical College of Ohio, and excite much rivalry in their respective departments. Five doctors, from Cincinnati and vicinity, are chosen in each arena to act as judges. They render their decision impartially, and hand it to Dr. Dawson in a sealed envelope, which he opens Commencement night and announces the successful names. The occasion is made a half-holiday, with Professor Dawson as Master of Ceremonies. A number of speeches are made, interesting cases shown, and the annual feast winds up the occasion. The students and profession greatly appreciate Dr. Dawson's great-heartedness and liberality.

The Electrical Treatment of Uterine Fibroids.—Dr. Apostoli, of Paris, attacked the method particularized by MM. Championnière and Davion at the meeting of the French Congress of Surgery. Their method is based on the employment of currents of moderate intensity, the extra-uterine action, and the reversed action. He claims the inferiority of this method for various reasons. Their statements are based on seven months' experience and eleven cases, while the method of Apostoli has been established seven years, has received the approval of all who have used it, and includes several thousand observations in France and other countries. They remain surgeons, and continue to perform castrations and hysterotomies. They select their cases, using the current on aged women or those but little sick, and operating on the young women. They admit failures which legitimize their surgical intervention. Their method remains vaginal and extra-uterine, preventing all cure of the accompanying endometritis. With them the relapses are constant if the treatment is not continued. They do not affirm as to the disposition of the inflammatory deposits. "La fonction des eaux chloruées sodiques," which they praise, shows that their method is at fault. They have not proved the evident anatomical reduction of the fibroma. Apostoli asserts the efficaciousness of his method: Because it has the pretension to suffice in itself, and in most cases to supplant surgery in the treatment of fibroma. It does not require the selection of cases, and all cases are ameliorated, young and old. Because failure is the exception in all cases of simple fibroid tumors, not fibro-cystic, which are not complicated by ascites, and without puerperal lesions of the annexes. Because there is utilized the action of vaginal galvano-punctures, either singly or in conjunction with the intra-uterine action, which is necessary for the endometritic lesions. Because relapses are the exception, and the greater part of the results remain constant if the treatment has been sufficiently prolonged. Because it embraces within its sphere of action, under formulæ of intensity and divers localization, the treatment of fibroma, that of endometritis and metritis, and of a great number of cases of ovaro-salpingitis.

Because it can do without an additional treatment, even that of les eaux chloruées sodiques. Because there has been observed an anatomical reduction of the fibroma, not total, but partial. His method is inoffensive and always supportable if the rules are conformed with, the very rare cases of death observed are due, in great measure, to errors in diagnosis, tumors of the appendage mistaken for fibroma and electrically treated. Apostoli claims the priority and paternity of all medical electrical applications exceeding fifty milliampères. For two years he has exclusively employed intensities from forty to seventy milliampères; since that time he has considered it necessary to increase, not in an exclusive and blind manner, as has been stated, but by a rational and progressive method, according to the cases. The intensity should be moderate in cases of uterine intolerance or peri-uterine affections; the intensity should be increased in all the grave forms complicated by endometritis or by hemorrhage. Aimé, Martin, and Chéron were the first ones to particularize (1879) the action extra-uterine, either on the neck or on the vagina, and were the first to use the reversals, or the interruptions of the galvanic current. Moutz Benedick, of Vienna, has also applied the reversed galvanic current before MM. Championnière and Davion.

The Travels of a Needle.—Surgeon T. Y. Baker reports, in the *British Medical Journal* of December 14, 1889, the case of a gunner who came to him complaining that "he had a bone in his leg." On examination, a hard substance was felt beneath the skin of the right leg, on its external aspect, about its middle third. On making a small incision, a large needle, measuring 3½ inches in length, was easily withdrawn. The needle was perfect as to its eye and point, but somewhat corroded. The patient had previously followed the trade of a portmanteau maker, and the needle was such as is generally used in that handicraft. His statement is that about last Christmas he was employed at his calling, when his fellow-workmen played him a trick by boring a hole in the bottom of the chair he worked in, and placing the needle, point upward in the hole, in such a manner that by means of a string it could be jerked upward into the victim's buttocks. This they did so successfully that the needle penetrated the tissues, and the string slipping off, it entirely disappeared in the gluteal muscle, leaving the subject of this practical joke in ignorance that the needle was retained in his flesh. The patient stated that he suffered much pain in the right hip and leg for about six weeks after, and was unable to work, and again in February, when probably the needle was passing the knee-joint; but he recovered completely and was able to enlist in the Royal Artillery. It is difficult to imagine how this large needle passed from the gluteal region down the thigh, over or under the knee, and made its way to the surface of the middle of the leg.

Cowhiding—More Blessed to Give than to Receive.—Cincinnati has had a sensation recently in a malpractice suit, which resulted in the attempt of two lawyers to cowhide the editor of a medical journal. In April, 1888, Dr. C. D. Palmer, Professor of Obstetrics and Diseases of Women and Clinical Gynecology in the Medical College of Ohio, and Gynecologist to the Cincinnati Hospital, operated on a woman, and during the operation one of his needles broke and the piece could not be found. A few days later the doctor met with an accident, his horse running away, throwing him out under a culvert, whence he was taken up for dead. He was taken to the Good Samaritan Hospital, where he lay in a semi-unconscious state for weeks, and was unable to return to his professional work for a year. When able to travel he went to the Atlantic coast, and afterward to California, and regained his lost health and strength to such a degree that his practice, hospital, and college work were resumed. During this time, while he is many thousand miles away seeking health, the woman goes to another doctor, complaining of great pain. Another operation is performed and, behold, a piece of needle is brought forth. Recently Dr. Palmer received a letter from a youthful firm of briefless barristers, intimating that unless he came down with some money he would be sued for damages. He refused to consider their proposition, and was sued for $10,000. This action was followed by a scathing editorial in the next number of the *Lancet-Clinic*, January 25th, from its editor, Dr. J. C. Culbertson. His were words that burn, the actual cautery applied with unsparing hand, which cut to the bone, penetrating nerves and tissue in all directions. The limbs of the law read, writhed, condemned, and sentenced the writer to a dose of cowhide. They sallied forth, with their cowhides fresh and new. They entered the doctor's office and, without presenting their cards, began using their pretty weapons. The editor, who was brought up on a big farm, soon recovered from his surprise, shook his powerful frame, took the weapons from the legal sprouts, gave them the dose they came to bestow upon him, walked to police headquarters with a cowhide in each hand and blood in his eye, and quieted official fears by telling them he had only come to swear out a warrant for assault and battery. It is to be hoped that the action of these two attorneys will not only lead to the dismissal of the case with these champions, but to the disbarment of the men who would resort to such means to retaliate on an editor. If lawyers cannot obtain redress at law, who can? The plain path for the medical profession to pursue is to stand together, to boycott lawyers who undertake these "bleeding" cases, destroy their business and political aspirations, where possible, and show that the medical profession is a unit, and a dangerous one to attack.

The Strangers' Cold.—A writer in the *Pall Mall Gazette* gives the following account of a curious phenomenon which has been noticed and commented upon by several observers before: During a seven years' residence in Norfolk Island—the well-known settlement of the descendants of the Bounty mutineers—he writes, he had opportunities of verifying the popular local tradition that the arrival of a vessel was almost invariably accompanied by an epidemic of influenza among the inhabitants of the island. In spite of the apparent remoteness of cause and effect, the connection had so strongly impressed itself on the mind of the Norfolk Islanders, that they were in the habit of distinguishing the successive outbreaks by the name of the vessel during whose visit it had occurred. But the phenomenon is not confined to Norfolk Island. Whatever may be its explanation, there are evidences of its appearance in widely sundered localities. In *Chambers's Journal* for July, 1888, an article headed "The Strangers' Cold," gives various instances of influenza appearing among remote populations simultaneously with the arrival of strange vessels on their coasts. The island of St. Kilda is quoted as having a fixed tradition to this effect, while in Wharekauri, an island about four hundred and thirty miles east of New Zealand, the circumstance is so well recognized that the mere appearance of the influenza is sufficient signal to the inhabitants of the interior that a strange vessel is in port.

A Uretero-uterine Fistula.—Professor Treub reports a case of this exceedingly rare character. A young woman, aged twenty-two, was delivered of a child for the first time where the forceps were required. After the confinement had been recovered from, a discharge still continued *per vaginam* of a fluid character like urine, but no seeming fistula of bladder or urethra could be discovered. She was received at the Leyden Hospital under the care of Professor Treub, who found on examination both sides of the os lacerated, but could discover no fistula. The discharge had an acid reaction, but how or where it got into the uterus could not be decided. The woman urinated twice a day by the natural channel. New milk was injected into the bladder, but none of it appeared in the discharge from the uterus! The woman went on urinating by both the urethra and the uterus without any pain

or trouble, except the discomfort of being constantly wet. The neck of the uterus was dilated by means of iodoform gauze, which produced a good deal of pain in the large intestine. After the finger could be passed into the uterus, Treub found that the fundus was dislocated toward the right and attached to the pelvis, and that a round tumor about the size of a hen's egg projected from the side of the organ, which up to this time had been taken for the organ itself. From this round smooth tumor the fluid seemed to be oozing away, as the perforation on its anterior side seemed to be very narrow. From the external appearance of the pelvis nothing appeared to shed light on the phenomenon. The fluid discharges from urethra and vagina were found to be equal, but that of the vagina was muddy and albuminous. The urethra was next dilated with Simon's instrument till a sound could be introduced. The mouths of the ureters were normal, but no urine was observed to exude from the right. A sound was introduced into the ureter, but could not be passed beyond one centimetre into the canal. Four weeks after this examination, when the catarrh had subsided in the bladder from the necessary rough handling, Treub resolved to remove the right kidney after Simon's method. The ureter as well as the blood-vessels were tied with catgut. The wound was washed with solution of iodoform, and dressed with iodoform gauze tampons. After fifteen days the tampons were withdrawn, the wound sewed up, a firm bandage applied, and the patient admonished to lie on the right side. In the meantime the catarrh of the bladder repeated itself as a complication, which was treated with injections of nitrate of silver and boracic water solutions, and healed favorably. Seventeen days after sewing the wound, seven of the stitches were removed, and on the twelfth all the others were withdrawn, while the wound healed by first intention. About three months after the operation the hard resisting swelling at the side of the uterus could still be found. The urine was perfectly clear, no albumin, and normal quantity, and the patient was dismissed from hospital. Three weeks later she returned, and the small tumor still remained, with a slight discharge from the uterus. The pathological appearance of the removed kidney showed considerable enlargement by thickening of the walls, while the ureter was about three millimetres wider in diameter than usual. The pelvis was greatly enlarged. On the upper part of the kidney was an enlarged swelling, which when cut into was found to be a small abscess forming the beginning of suppurative pyelo-nephritis. The importance of this case may be understood by a reference to the literature of the subject. There are only eleven cases to be found on record, including this one of Treub. Of these it occurred six times in the left ureter, three times in the right ureter, and twice it is undefined.—*Medical Press.*

Hypochondriasis.—Professor Mendel, in a lecture before the Association of Physicians at Berlin, defines hypochondria as a functional disease of the brain, the essential symptoms of which are fear and anxiety about the patient's own state of health. The disease appears, according to Professor Mendel, in three different forms. The simplest of these forms, for which the lecturer proposes the name of nosophobia, is when the patient considers himself seriously ill or near death. The second form shows not only the same fear and anxiety, but also various organic hallucinations. The internal organs have probably, like the extremities, a centre in the cortex, and any irritation of this centre will usually produce a special class of sensations, which in this case become hallucinations. The third form shows, in addition to all the foregoing symptoms, hallucinations of the higher senses. Patients believe their hearing and sight are getting worse. They also sometimes hear voices, as it were within the head. The affection is, according to the course it takes, divided into acute, subacute, and chronic or constitutional hypochondria. Contrary to a general belief, it is very frequent among females of every age. Nosophobia is certainly much more frequent in man, probably because women act as nurses, and consequently have no fear of infection. The second form is very frequent among women, and is generally connected with the sexual organs. These patients generally come under the care of the neurologist only after having become much worse through unsuccessful gynecological treatment. The so-called cerebral form is most frequent. Patients say that their head feels as if it were in a vice, or that it is soft, empty, or too light, and that the spinal column cannot support it. They are consequently in fear of apoplexy or insanity. The third form appears chiefly among women. Patients fancy themselves altered; when standing before a looking-glass they believe their faces to be wrinkled, etc. They fear that their means will become insufficient to live upon, that they will lose their place, and they suffer from claustrophobia. Hypochondriacs are characteristically egotistic. This symptom is more prominent in women than in men. One woman kept her bed for twenty-five years, without any disease, and committed suicide in bed. Generally, however, suicide is rarer in hypochondriacal women than in men. Sleep is generally good. Paræsthesia and hyperæsthesia are frequent, as are also cold feet, while the head is warm. Professor Mendel has frequently discovered a spot on the head of such patients which felt hotter to the hand than the rest of the head. In complications of hypochondriasis with other affections (hypochondria cum materia), Dr. Mendel teaches that the latter are the cause of the neurosis. Especially important is the complication with hysteria, which is generally the primary affection.—*The Lancet.*

The Way of the Doctor is Sometimes Hard.—One of the best known physicians in New York remarked the other day that in eleven years he had accumulated $25,000 of absolutely bad debts on his books. This was apart from more than as much more he had to collect by legal means, and some of which was doubtless also hopeless. He had never sued a debtor or put a collector on him until a couple of years before, when the steady increase of the dead-wood on his account books forced him to do it. It is beyond question that his case is only one of many. There is probably not a doctor in the city who is not a heavy loser by unpaid fees, and the higher his standing the heavier his losses. It is getting to be quite common now for men to be sued for doctors' bills. The other day I was talking on Broadway to a dry goods merchant worth a cold million at least, when he was served with a summons. He commenced to warm the winter wind with heated observations. The summons was for a bill of $150 for medical attendance on his wife at a hotel, while he was at the Paris Exposition. And what is more, from all I know, the money was fairly earned, for the woman was narrowly saved from a death invited by her own carelessness and defiance of sanitary laws. Yet the husband allows himself to be taken into courts, with the chance of having the whole story of the case made public, rather than pay a deserving young doctor the little money he owed him. I asked this person why he did not pay the bill and spare himself the trouble of being dunned for it. "Oh, —— these doctors' bills," said he, "I'd never pay one if I could help it," and there are doubtless plenty of people of his way of thinking among us.—*New York News.*

Perseverance Rewarded.—Dr. Nieden reports, in the *Centralblatt fur Gynäkologie*, December 14, 1889, the case of a married couple who had lived many years in America, and were childless. They returned to Germany to celebrate their silver wedding, and concluded to remain there. Soon after their arrival the woman's menses ceased, and she supposed that it was the menopause, but was surprised later to find that she was pregnant, and in due course gave birth to a healthy child. Dr. Nieden adds that there was not the slightest question as to the paternity of the child.

Dr. Motais.—The name Dr. Matais, of Angers, mentioned in the Paris letter which was published in the RECORD of January 4th, should have been printed Motais.

Our Streets.—New York has 574.88 miles of streets to clean, and there are collected half a million cubic yards of street-sweepings and one and one-half million cubic yards of garbage and refuse yearly, at an annual cost of about one million dollars.

The International Centralblatt für die Physiologie und Pathologie der Harn- und Sexual-organe is the name of a new monthly edited by Dr. W. Zuelzer, and published at Hamburg and Leipzig.

A Much-advertised Asylum.—By some ingenious method the Middletown Insane Asylum always manages to get a long annual notice in the daily press, in which statements are made to the effect that this institution is under the care of a most distinguished alienist (name given), and that the results of treatment are superior to those elsewhere. Such fulsome notices are in bad taste, and do, indirectly, an injustice to other, and, in fact, better-equipped and conducted State asylums.

Woman's Obstinacy.—In a book entitled "New Views of the Process of Defecation," by Dr. O'Beirne, of Dublin, a case is cited of a girl, nineteen years of age, who had not a stool of any kind, or passed even flatus per anum since early in the preceding December, a period of nearly six months.

An Impatient Child.—A case of Cæsarean section was down on the bills at one of our city clinics the other day, but the child would not wait, and came into the world by the usual route before the clinic day arrived.—*Times and Register.*

The Credé Method of expelling the placenta is said to have been abandoned by its author, who admits that it may have done more harm than good to the lying-in woman.

Der Fortschritt, a journal of pharmacy and therapeutics, published in Geneva, has gone out of existence at the end of its fifth year.

The Danish Pharmacopœia.—A committee of physicians and pharmacists is at present sitting in Copenhagen preparing a new edition of the pharmacopœia. Delegates are also present from Sweden and Norway in order that all the Scandinavian pharmacopœias may be as nearly as possible in agreement.

The Death-rate in Texas, from all causes except accident, murder, and suicide, is estimated by the inhabitants as being 8.33 per 1,000 inhabitants. A Memphis contemporary innocently asks what the death-rate would be without the foregoing exceptions.

The Langenbeck House in Berlin.—This building, which is to be the common home for all the medical societies in Berlin, will be ready for occupancy, it is hoped, in about two years. The owner of the house will be the German Surgical Association, which has devoted its surplus of $25,000 to the erection of the building. About $20,000 has been collected by subscription, of which the Germans in this country have contributed about $2,500.

The People of Boston, according to the estimate of a local journal, consumed about a ton of quinine in the course of ten days while the influenza was at its height. That is about four grains a day for each man, woman, and child in that city.

Why the Japanese Stoop.—Dr. Kidera Yasuatsu has been inquiring into the cause of the habitual stoop of the Japanese, and concludes that it is due to their excessive politeness, the bent posture being considered one of deference.

The Insane in Manitoba are quartered in the penitentiary. The Northwest is a newly settled country, but its inhabitants seem to be imbued with some last-century notions.

To Practise Deep Breathing.—1. Stand erect, the feet separated, the right slightly in advance. 2. Shoulders and head in natural position. 3. Hands lying lightly on the abdomen, the fingers pointing to the umbilicus. Compliance with this rule enables the child to be sure she is using the abdominal as well as the pectoral muscles in respiration. 4. Empty the lungs of air, then close the mouth. 5. Inhale slowly through the nostrils, using abdominal as well as chest muscles. The lungs thus receive the utmost possible amount of pure oxygen and the muscles have exercise. 6. Hold the breath as long as possible, and meanwhile use the ordinary calisthenic exercises. 7. Never exercise except with the chest well expanded with air. 8. Exhale slowly, enunciating the vowel sounds as the air passes the lips.

Toxic Effects of Sulphonal.—Mr. Hutchinson records, in his *Archives of Surgery*, a case which illustrates the unpleasant symptoms that may result from the abuse of sulphonal. His patient was a lady, who came to be operated upon for epithelial cancer of the vulva; her manner and the want of interest she showed in the proposed operation caused him to regard her as an idiot. After the operation she had retention of urine; on the following day she had an erythematous eruption all over her thighs, the skin becoming everywhere of a deep red tint without papules or other changes. On the second day after the operation there was an improvement in the patient's manner, and this continued every day until she was as bright and cheerful as possible; at the same time she lost the heavy, sottish expression which before she had worn. After continuing out about four days, the eruption completely and rapidly disappeared. It was subsequently ascertained that up to the time of her coming under his care she had been taking sulphonal in repeated doses. The remarkable feature in the case was that the apparent idiocy should have lasted so long after the disuse of the drug, and that the eruption (if it was dependent upon this cause) should not have shown itself at all until at least three days after the discontinuance of the hypnotic.—*The Practitioner.*

The Pope Instinctively a Sanitarian.—We have, more than once, ventured the assertion that all really great men are, in practice, if not in theory, sanitarians; that they are so constituted naturally that a natural or hygienic life comes, so to speak, natural to them. They do what nature intends that they should do, because they are not, instinctively, urged to do otherwise. Such persons we might call natural or instinctive sanitarians. Then again we have those who live naturally, not because instinct so prompts, but because wisdom so dictates. In these two classes, we venture to say, if we fairly examine the question, will be found all really and truly great men. The present Pope, Leo XIII., is a remarkable illustration of the results of a natural, simple life. There are few persons in the world, even of half his great age, who possess the clearness of intellect and the capacity for work that he displays. Yet, had he not been careful of his health, he would surely have been in his grave many years ago, for he is not, and never has been, robust. The frugal, simple, natural life of the Pope furnishes a most admirable example for those who would desire to live long, healthy, happy, and useful lives.—*Annals of Hygiene.*

Doctors Disagreeing.—A Greek physician, practising in Constantinople not long ago, became so incensed with an Armenian *confrère*, who ventured to dispute his diagnosis, that he challenged him to a duel. The result was that he was arrested and sentenced to imprisonment for a year. He was very foolish, for the autopsy would have settled the point in a much more satisfactory manner to all concerned, except, possibly, the patient.

BACTERIAL STUDIES ON THE INFLUENZA AND ITS COMPLICATING PNEUMONIA.

By T. MITCHELL PRUDDEN, M.D.,

DIRECTOR OF THE LABORATORY OF THE ALUMNI ASSOCIATION OF THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

THERE are so many features which the disease called familiarly *la grippe* shares with the more common and more completely studied acute infectious diseases that medical men have pretty generally agreed in classing it with these, in spite of its marked peculiarities and the wide variation in its manifestations. Furthermore, so much positive knowledge has been recently accumulated regarding the etiology of many of the acute infectious diseases that the assumption that the epidemic influenza is probably caused by some kind of micro-organism seems fairly justifiable on the ground of its clinical manifestations alone.

But we have as yet no positive knowledge whatsoever as to the exact nature of the assumed micro-organism. By the aid of the new technique for the study of micro-organisms no investigations have yet been made on this subject whose results have been formulated and published.

Now it so happens that nearly all of the acute infectious diseases whose etiology has been satisfactorily established on a basis of actual observation and experiment have been proved to be caused by bacteria; that is to say, by micro-organisms which belong to a particular class or group.

So important has this group of micro-organisms called the bacteria appeared to be, in the light of recent studies, that in the minds of many, perhaps most, medical men the terms bacteria and micro-organisms are synonymous. But we ought not to lose sight of the fact that while we know that several diseases, among which may be mentioned tuberculosis, anthrax, erysipelas, pneumonia, typhoid fever, relapsing fever, etc., are caused by bacteria, there is a large and important group—small-pox, measles, scarlatina, yellow fever—about the relationship of which to micro-organisms we know, except by inference, practically nothing at all. These latter diseases, too, stand so apart from the others in their clinical manifestations and mode of transmission that it must be assumed that their peculiarities and the fact that we know as yet so little about them, in spite of much recent careful study, may be due to some marked difference in their etiological factors. In other words, it is not improbable that the exanthemata, for example, and yellow fever may be caused, not by bacteria at all, but by some other kind of micro-organisms which our present means of study do not enable us to take cognizance of or cultivate in the usual way.

This possibility becomes very comprehensible in view of what we know about the malarial organisms, which, although causing marked disease, cannot as yet be studied by the culture methods known and practised by the bacteriologist. There seems to be, both in the clinical manifestations and in the mode of spread of *la grippe*, much to suggest, not, indeed, that in its etiology it may be allied to malaria, but that it may stand related in its etiology to the better known acute infectious diseases much as malaria does—that is, may be due to a micro-organism, but to one of an entirely different class. The *plasmodium malariæ* belongs not among the bacteria or their close allies at all, but among an entirely different group of living beings. We might apparently have gone on trying to make something grow out of malarial blood upon our nutrient gelatine and agar, etc., indefinitely, if the constant presence of the disease with us had not permitted such morphological studies as have led to fairly definite notions as to its etiology, without recourse to the more subtle culture methods.

But whatever the truth of the matter may be concerning the assumed germ of epidemic influenza, it is evident that studies with the current bacteriological technique should not be neglected until they are proven to be useless, or some better method of observation is made known. For even negative results may throw a side light on this or closely allied problems.

Cases of Simple Influenza.—The number of cases of simple influenza which the writer has studied by the current bacteriological methods will appear very small to those physicians whose clinical observations during the recent epidemic extended to scores, if not hundreds, of cases. But so time-consuming is thorough bacteriological work on the etiology of disease that the whole available time of the writer during the epidemic was consumed in the study of material derived from seven cases. These were all unmistakable cases of the disease, but presented varying phases of symptoms.

In three of the cases there was bronchitis, with considerable muco-purulent expectoration. In the remainder there was moderate coryza, in two with considerable, in two with slight discharge. In all but one the discharge was obtained in the early stages of the disease, in that one on the fifth day.

Cultures were made on agar and agar-glycerine plates, at the temperature of the body, several plates from each case, and all of the more abundant bacterial species which developed were isolated and subjected to further examination and experiment.

The results of this series of studies may be summed up in a very few words. In two of the three cases of influenza associated with bronchitis there were very large numbers of Streptococcus pyogenes; this was the prevailing species. All the rest were scattering forms, commonly found in the sputum in bronchitis, most of them the ordinary aërial bacteria. In the other case of bronchitis there were large numbers of the Diplococcus pneumoniæ of Fraenkel and Weichselbaum, associated with a few Staphylococcus pyogenes aureus, and several scattering forms.

In the secretion from the nose of one of the cases with coryza were a few of the Staphylococcus pyogenes aureus, while all the rest, which were not numerous, were scattering forms.[1]

Influenza Cases associated with Pneumonia.—Let us turn now to the pneumonia which has been so frequent, and in many cases so serious, a complication of influenza in our recent epidemic. I have examined by the culture methods the sputum from five cases suffering from a prolonged and irregular pneumonia immediately following the influenza attack, all hospital cases; also the irregularly hepatized lung from a fatal case of pneumonia following influenza; six cases of pneumonia following influenza in all.

[1] While the secultures were being made the scanty sputum from a case of moderately severe simple pharyngitis was studied in the same way, and in this very large numbers of the Diplococcus pneumoniæ were isolated, together with a considerable number of scattering forms.

The cultures of the sputum of the first five cases showed enormous numbers of the Diplococcus pneumoniæ in four. In all of these four cases there were also considerable numbers of Staphylococcus pyogenes aureus, together with moderate numbers of other scattering forms—and in one, large numbers of Streptococcus pyogenes. In the fifth sputum specimen there were very large numbers of Streptococcus pyogenes and Staphylococcus pyogenes aureus, and a considerable number of scattering forms. From the lung of the fatal case enormous numbers of the Diplococcus pneumoniæ were cultivated, and nothing else. It was a pure culture.

Thus in five out of six cases of prolonged and irregular pneumonia following influenza, the Diplococcus pneumoniæ was found, being identified in all five cases by culture and by animal inoculation. The only other pathogenic species found was the Streptococcus pyogenes, and the Staphylococcus pyogenes aureus.

Summary.—If now we sum up the whole series of examinations we find that in the secretions from seven cases of simple influenza no special new forms of bacteria were discovered which there is reason to believe have anything to do with causing the disease. The only pathogenic species which were found were the well-known pyogenic bacteria, Staphylococcus pyogenes aureus, Streptococcus pyogenes (in four of the cases), and the Diplococcus pneumoniæ (in one of the cases). In the pneumonia following the influenza (six cases) we also found no special new forms of bacteria but the same pyogenic forms (in five of the cases) and the Diplococcus pneumoniæ (five cases).

Conclusions and Remarks.—Thus while we gain no positive new light on the etiology of epidemic influenza in this series of examinations, we are able, from the results of the studies on the pneumonia which accompanies it, to establish the probability that the pneumonia, although apt to be irregular in its course and atypical in its morphology, is usually due to the same bacterial agency as is at work in the ordinary acute lobar pneumonia. How much this may be further complicated by the frequent presence of the pyogenic bacteria is a question which must be settled by further studies on the general relationship of these organisms to inflammations of the respiratory organs and to other mucous membranes.

It would seem from these studies, furthermore, that the relationship of the influenza to the pneumonia is that of a predisposing factor only—a conclusion, indeed, toward which clinical investigators have been already led by a different line of observations.

The phase of pneumonia which this epidemic has brought into prominence, is instructive in its relationship to the ordinary typical acute lobar pneumonia. It seems pretty well established that the Diplococcus pneumoniæ of Fraenkel and Weichselbaum is the most common, if not the exclusive, primary etiological factor in acute lobar pneumonia, judging from its constant occurrence in the affected regions, from its pathogenic effects upon animals in experimental inoculation, and from its frequent occurrence in complicating lesions.

The very frequent occurrence of this micro organism in the saliva of healthy persons not only does not militate against its etiological importance, but furnishes a most satisfactory rationale of the occurrence of the disease. For under ordinary conditions the Diplococcus pneumoniæ appears to be quite harmless in the saliva. It is only when the suitable predisposing conditions—which we recognize in injuries, and in exposure to cold and wet, but which in many cases we do not understand at all—are fulfilled, that the growth of the germ in the lungs and its accompanying lesions can occur.

It would seem that the influenza, with its tendency to an involvement of the respiratory passages, furnishes, not indeed the common, but an analogous predisposing condition leading to an atypical pneumonia. This form of predisposition to pneumonia seems to be, in many respects, similar to that which measles furnishes in children to the incursions of varying forms of pulmonary inflammation whose determining etiological factors have not yet been sufficiently studied.

It may be remarked in conclusion that to the negative results of these studies on the influenza only such importance should be attached as the small number of cases examined will justify. We simply learn that in these few cases the use of the culture methods and media commonly employed in the study of bacteria and allied forms of micro-organisms has brought to light no living germ which there is reason to believe has anything to do with causing the disease.

But this negative result should leave us entirely unprejudiced toward any other series of observations which, with more abundant material and a more refined or favorably applied technique may promise a solution of the problem.[1]

February 3, 1890.

THE SURGICAL TREATMENT OF LOCAL AND GENERAL PERITONITIS, WITH REPORT OF TWO CASES OF GENERAL PERITONITIS DUE TO PERFORATION SUCCESSFULLY TREATED BY FREE INCISIONS, IRRIGATION, AND DRAINAGE.[2]

By W. GILL WYLIE, M.D.,

NEW YORK.

My excuse for bringing this subject before you to-night is its importance, and the firm conviction that there are hundreds of men and women dying from peritonitis who might be easily saved if the medical profession would recognize the fact that a majority of such cases could be saved by prompt surgical interference.

The number of cases occurring in every town of any size is incredible to anyone who is not specially interested in studying the subject.

Here in New York, where one would suppose well-to-do patients would not be denied in many cases the only chance of being helped by laparotomy or surgical treatment, not one in ten have the question of operation considered, unless all other means fail, and then, with rare exceptions in cases of general peritonitis, it is too late.

For the past seven years I have worked faithfully with my gynecological colleagues to try and convince them that, practically speaking, there is no such thing as chronic pelvic cellulitis; that the so-called cases of cellulitis—especially those called chronic, where "attacks of cellulitis" are constantly "being lighted up"—are nothing more nor less than cases of local peritonitis due to salpingitis and ovaritis, *and when there is positive evidence of the formation of pus, or the patient is bedridden from frequent attacks, that the only rational treatment is by laparotomy.* That pelvic abscesses, nine times out of ten, are merely the result or the sequel of neglected cases of local peritonitis, and although when actively septic and readily reached by the vagina *behind the uterus* they should be opened and drained; but the only radical and certain cure is, as a rule, by laparotomy. And that when laparotomy is resorted to, the pus should be first carefully drawn off and the sac rendered aseptic by washing it out with antiseptics, and not sewn into the abdominal wound, but enucleated and removed with the diseased tube and ovary nearly always found in it. Even during the acute stage of either local or general peritonitis laparotomy should be done, if life is threatened either by sepsis or intestinal obstruction.

[1] While this article was in press the results of a similar study on the influenza, by Rikert, in Bonn, reached this country in the Deutsche Medicinische Wochenschrift, of date of January 23, 1890. His bacteriological study of five cases of influenza, two of which were without, the others with, pneumonia, showed that the only species constantly present was the Streptococcus pyogenes. The Diplococcus pneumoniæ he did not find at all. He very guardedly suggests the possibility that the Streptococcus, in association with some unknown peculiar atmospheric condition, may cause the disease. Whether this be true or not, he would lay stress upon the probable importance of the Streptococcus in inducing the various complications.

[2] Read before the New York Academy of Medicine, January 4, 1890.

Success has overcome almost all opposition among gynecologists, and as a rule the above is the accepted practice. When I began, I was accused of mutilating women, and even to-day some of my old teachers, while admitting my success to those who ask about me, still claim that I am too fond of the knife.

Although I do not now practise general surgery, I am interested in all abdominal surgery, and I am convinced that the general surgeons will soon adopt about the same rules of procedure in treating local and general peritonitis occurring in the abdomen that gynecologists have established as the best plan of treating pelvic peritonitis.

My experience in peritonitis from typhlitis or perforation, is limited, but my large experience in peritonitis, the result of salpingitis, warrants me in at least stating my views.

The general surgeons have been lately going through the discussion as to whether the abscesses formed about the vermiform appendix and cæcum are intra- or extra-peritoneal. It is exactly similar to what gynecologists have years ago been through in regard to pelvic abscesses. I believe that the intra-peritoneal theory is the right one in both cases.

As a rule, at least, it would seem that typhlitis is due to ulceration through the appendix or intestine, causing in most cases a local peritonitis around the centre of ulceration; as pus is formed it is shut off and encysted by lymph from the free peritoneal cavity, and gradually an abscess of greater or less size is formed, unless the opening in the gut is so large, or the septic matter escaping is so virulent, that general peritonitis at once is set up.

Once the abscess is encysted, the tendency of the peritoneum is to protect itself by forcing out the pus into the connective tissue, or through the wall of the intestine, either through the original point of ulceration or a new one. This is precisely the same with pelvic abscesses around the Fallopian tubes, and in many cases nature effects a cure and helps on the conservative argument; but he must be a small man who sits by and takes the credit of curing the case by letting the patient run three out of four chances of dying, instead of operating, and giving at least nine out of ten chances to get well by establishing a free and safe outlet for the pus. When the peritonitis is local the symptoms are, first, a severe colicky pain over the abdomen, in the first few hours usually most marked about the umbilicus; but soon the pain becomes most marked directly over the region of the appendix, and after the first twenty-four hours distinct tenderness will be localized in the same region. There may be vomiting, but, as a rule, the symptoms of intestinal obstruction are not present, or are only temporary in character. There are usually pretty well marked chills or chilly sensations, with some rise of temperature, usually not over 101° or 102° F.

For several days, usually four or five, the symptoms will vary, the pulse may be at times not above normal, and the temperature may even sink to normal and the bowels move, yet the local pain, or at least pain on pressure over the vermiform process remains, and may be the only indication of the presence of a pint of stinking septic pus which is liable at any moment to burst into the free peritoneal cavity and cause death in twenty-four hours. This condition was perfectly illustrated by my second case. Usually on the fifth, sixth, or seventh day the abscess will find an outlet or burst and cause general peritonitis.

As a rule, if the case starts as one of general peritonitis, it will not end fatally in twenty-four or forty-eight hours, as is the rule when a large septic abscess bursts after five or six days of local peritonitis, but the colicky pains will be more intense and persistent than in local peritonitis, and the vomiting and constipation or intestinal obstruction will be persistent or readily provoked by attempts to feed, etc.

The patient may live four or five days or even longer, if kept quiet and under the influence of opium, but unless operated upon before marked shock is present, will die with absolute certainty.

The following are short histories of the five cases of typhlitis and perforation that I have had to deal with. They fairly illustrate the most important points in local and general peritonitis starting from that locality.

I have operated upon more than two hundred cases, either during or while the patients were suffering from the results of local peritonitis starting from the Fallopian tubes or ovaries. In quite a number of these there was suppurative general peritonitis, and operation was performed when pulse was 110 to 120, and temperature 103° to 104½° F.; but such cases with gynecologists are no longer rare, and the necessary steps of operating are now very generally accepted. But it is not so with local and general peritonitis starting from the vermiform or cæcum, which are usually treated by physicians and operated upon by general surgeons. In several cases of salpingitis I have found the appendix adherent to the tube or ovary, and thrice I tied it off for hemorrhage from it when the adhesions were separated, and all of these recovered.

Case I. *Intestinal Perforation; Local Peritonitis; Perityphlitic Abscess.*—Negro man, aged twenty-two, was admitted to Bellevue Hospital, August 24, 1885. He was sent to the medical side as a case of peritonitis. In the absence of my colleague I was asked to see the man. He said that for about a week he had had great pain over the abdomen, with considerable fever, sweating, and chilly feeling. He had a temperature of 102½° F., with a quick pulse and rapid respiration. His abdomen was distended, hard, and tense, and very sensitive to the touch, especially over the right iliac region, where he said now was the point of greatest pain. He had been constipated and vomited some, but his bowels moved with an enema. There were some, but not positive, signs of the presence of a tumor. I decided that there were indications of pus, and he should be operated on at once. Dr. Janeway and Dr. Stimson saw the case, but differed with me about the indications for operation. Later in the day the late Dr. McBride saw the man, and he agreed with me that there was pus. I had the patient etherized, and could then readily make out the presence of a tumor the size of a cocoanut near the crest of the right iliac bone, within half an inch of the bone. I made an incision about three inches long. When the peritoneum was reached, I dissected down near the bone, so as to get somewhat under the side of the tumor, and to be sure to open it where it was firmly adherent to the parietal peritoneum, for I wanted to prevent the escape of the pus into the general cavity of the peritoneum. I found the muscle grayish in color, the change from the normal red color being due to slight infiltration from proximity to the inflamed tissues. I have since found this grayish color of the muscle to be a good guide in seeking a point where the sac of the tumor is adherent. With a pair of sharp-pointed forceps I carefully opened the sac of the abscess, and at once a strong spurt of fetid pus gushed out, at least a pint of dirty-colored pus with strong fecal odor escaped. The cavity was well washed with a solution 1 to 3,000, hydrarg. bichlor., and a double drainage-tube inserted. The patient's pulse fell to normal, and he made an uninterrupted recovery, and left the hospital in three weeks.

Case II. *Intestinal Perforation; Local Peritonitis; Perityphlitic Abscess.*—Male, aged thirty-seven; a strong, vigorous man. While sitting in a saloon had a violent cramping pain of the abdomen; he took some hot spiced drinks and was carried home. He suffered intense pain and sent for me the next day. His abdomen was distended and sensitive, and he had vomited some; the pain was most marked over the umbilicus; his temperature was 101° F., and pulse 105; respiration, 25. I gave him a hypodermic of morphine, and ordered a laxative for the next morning. The next day the pain was less, but more decidedly sensitive over the right side; his temperature was only 100° F., and he felt generally better after his bowels moved. The third day he had a chilly sensation, and temperature was 102° F. I kept him in bed and on

a milk diet. The fourth day he was better, but still had decided pain over the right iliac region, and was constipated. He was very fat, with not less than three inches of adipose tissue over the abdominal walls, and I could not make out a tumor, nor could I make out anything by rectal examination; but on account of the pain and decided sensitiveness over the region of the cæcum I determined to call a consultation, and refused to call a medical man. Dr. L. A. Stimson was selected. He could not make out any tumor, but agreed with me that the patient should take ether, and, if necessary, have an incision made. He was ordered a dose of castor-oil. On the morning of the fifth day his bowels moved freely and without trouble, his temperature and pulse were absolutely normal, but, as the local pain was still very marked, he was given ether. When fully relaxed we could, through all the fat, make out indistinctly a tumor near the ilium. A free incision about three and a half inches long was made, and, when the peritoneum was reached, it was plain that we were in contact with a large, fluctuating mass. Selecting a point as far back as could be readily reached, I opened the peritoneum with sharp-pointed forceps and out gushed a strong stream of stinking pus with a very decided fecal odor. The opening was enlarged and the abscess well washed out with 1 to 3,000 hydrarg. bichloride. There was no escape of fæces or gas, and when my finger was in I could feel the walls of the abscess, but made out nothing of importance. A double drainage-tube was inserted, and the upper end of the incision closed. The patient never had any rise of temperature or pulse, and in three weeks was sitting up. During the second week a nucleus of hard fecal matter, with ground up seeds like those of strawberries, came out of the wound, and soon it closed from the bottom. There has never been any return of the trouble, but a decided hernia exists, and a truss is necessary to prevent its increase in size.

Case III. *A Case of General Peritonitis, due to Bursting of a Typhlitic Abscess* (October 26, 1888).—This case was fully reported by Dr. A. M. Jacobus in the Medical Record, February 2, 1889. Man, aged fifty, in good physical health, was taken with severe colicky pains on Saturday. On Monday the pains became very severe; on Tuesday he sent for Dr. Jacobus. The doctor found him lying with his knees drawn up, the abdomen tense and very sensitive to the touch, especially over the cæcum; he was constipated. He was ordered to bed, and one-eighth grain of morphine and three-eighths of a grain of antipyrine given every three hours as indicated. Saline laxative was given the next morning. Wednesday he was better, had a full stool, but was still in pain, especially on the right side; temperature, 100⅕° F. Thursday afternoon he grew worse, and the doctor detected some signs of a tumor over the region of the cæcum which confirmed his diagnosis of perityphlitis. Friday, the fifth day, at 6.30 A.M., he was taken with violent cramping pains and rapidly developed all the symptoms of general peritonitis. At 9 A.M. he had a violent chill, and temperature went to 102° F., and pulse to 110. At 11.30 I saw him, and decided to operate at once. The abdomen was exceedingly tense and very hard, but no signs of a tumor could be detected under ether. I opened the abdomen in the median line just below the umbilicus, and, as soon as the peritoneum was opened, out gushed a quantity of purulent serum and flakes of lymph. Introducing my fingers, I made out a collapsed abscess sac over the appendix vermiformis. I then made another opening through the abdominal wound directly over this point. I inserted a large-sized glass drainage-tube, attached to the tube of a large fountain-syringe, and washed out the whole abdominal cavity. Introduced my hand and separated the adherent coils of intestines, and again washed out the peritoneum. I found puddles of pus scattered among the coils of intestines which even the second washing out did not reach, and again went over the abdominal cavity with my hand, and again washed out till the water came away perfectly clear. The pus-sac was freely opened, and the bean which had ulcerated was found. As there was no escape of fecal matter or gas the adhesions about the appendix were not disturbed. A glass drainage-tube was inserted through both the median and lateral incisions, the latter going directly into the remains of the abscess-sac. The wounds were closed with silk and dressed in the usual manner. In less than two hours the temperature fell to normal and the pulse to 90. The case was treated in the usual way, nothing by the mouth for thirty-six or forty-eight hours, warm rectal enemas for thirst. The drainage-tubes were sucked dry every few hours. The central one was removed on the third day, and the lateral on the eighth day. The sixth day the sutures were removed, and, while angry with his nurse, the patient raised on his elbow to drink a glass of water and burst the median incision, the intestines escaping from under the dressings. They were carefully washed, returned, and in an hour I closed the wound with silk sutures without ether. The temperature rose slightly, but a laxative brought it down, and he made an uninterrupted recovery and has been well since then.

Case IV. *Intestinal Perforation of Cæcum; General Septic Peritonitis.*—J. McG——, aged twenty-eight; good family history, strong and healthy, never had venereal disease, good habits; mechanic. February 5, 1889, he had some heavy lifting to do, but quit work at six o'clock feeling all right, ate a simple supper. About 9 P.M. he had a very severe cramping pain, most marked over the right side of his abdomen. By two o'clock the pain was agonizing and Dr. Ernest Walker, living next door, was sent for, who gave him hypodermics of morphine, one-sixth grain, and one grain calomel by the mouth until the pain was in a great measure relieved.

The next morning the whole abdomen was extremely sensitive to touch, and the abdominal walls as hard as boards, with some distention. The pain was very severe and decidedly more marked over the region of the umbilicus. During the day vomiting set in. More morphine was given and attempts made to move the bowels by enemas, but they were retained. Hot applications were made over the abdomen. Thursday the pain was still severe and most sensitive over right side, and temperature up to 101° F., pulse 110. Four seidlitz powders an hour apart and an ox-gall enema were given, but all of no avail. Some spinach-green vomiting. I saw the patient Thursday; his general condition was good, but all symptoms of general peritonitis were well marked. I had him sent to Bellevue Hospital. Before operation enemas were given but were retained, rectal tube let off gas and gave some relief. Temperature was only 100.6 F.; pulse, 106; but respirations were 30. Ether was given. As no signs of a tumor could be made out I opened the abdomen in the median line just below the umbilicus. When the peritoneum was opened abundant purulent serum poured out as soon as the adhesions of lymph were broken up with the finger. In passing the index finger over toward the cæcum the pus became more abundant and had a decidedly fecal odor. I could not make out any signs of a local abscess or sac of one, but decided that the region of the cæcum was the starting point of the peritonitis. I then made an incision through the abdominal wall just over the cæcum. Through the median incision I introduced a large-sized glass drainage-tube, which was attached to a large fountain syringe containing two gallons of hot water at 112° F. I handled the tube so as to wash out all the excess of pus about the cæcum. I then broke up all adhesions of the intestines in every part of the abdomen and pelvis except about the cæcum, and washed with six or eight gallons of hot water till it came out perfectly clean. By opening the lateral incision the point of perforation in the cæcum, sealed over with lymph, could be plainly seen. It was circular in shape and about two-fifths of an inch in diameter. The appendix pointed upward, was somewhat adherent, but appeared nearly normal. A glass drainage-tube was put in both openings and the incisions closed around them in the usual manner with silk sutures, and the wound dressed with iodoform gauze, absorbent cotton, etc.

The operation lasted about one hour, there were no signs of shock at any time, and the patient's pulse was as good, if not better, after than before the operation.

He made an uninterrupted recovery, his temperature was never above 101° F., the pulse 104, and after the third day it was practically normal; tympanites and pain had entirely left him. The glass drainage-tube in the median line was removed the third day, but the other tube drained rather freely and had some fecal odor for several days. The edges of the wounds, especially the lateral one, sloughed and gaped on fifth and sixth days when the stitches were removed. The discharge was irritating and the peritoneum seemed, when assisted by drainage, to take better care of itself than the connective tissue and muscles. I have noticed this in all of my four cases of intestinal perforation. The sloughing incisions were marked in all of them, while in peritonitis from salpingitis it is exceedingly rare. Thirty hours after operation a simple enema was given and bowels moved freely without trouble. After this, one small dose of morphine was given, and it was the only one after the operation. After bowels moved, kumyss and pancreated milk were given. On third day his bowels moved very freely and the amount of food was increased. On account of the lateral incision closing as an open wound he did not sit up till the end of the third week, but went out of the hospital, perfectly well, at the end of five weeks.

Case V. (September 28, 1889).—I went to the northern part of New York State to see a woman, forty-eight years of age, who had in the past ten days developed a tumor, which was very painful, on the right side just above the crest of the ilium. The history was the usual one of a slow developing abscess about the vermiform appendix. Before I saw her several ounces of pus had been drawn off with an aspirator. I could plainly make out a tumor the size of a large cocoanut. The tissues near the ilium were somewhat indurated. She was etherized, and I made an incision near the crest of the ilium, extending backward; when I reached the muscles they were grayish and infiltrated. It was evident that the sac of the abscess was firmly adherent to the lateral wall of the abdomen, and that I could safely open the abscess-cavity without entering the general peritoneal cavity; this I did, and out gushed about a quart of fetid pus. I inserted my finger, enlarged the opening, and put in a double rubber drainage-tube. The tubes drained freely for several days and were then shortened, and in the fourth week the wound was healed and patient got well.

Conclusion.—When there are symptoms of local peritonitis, intense pain and tenderness, followed by tympanites and vomiting, with chilly sensations and rise of temperature, search should be made for the cause. As a rule the pain will soon become localized over the region of the Fallopian tubes, the cæcum, or gall-bladder, or some old ventral or inguinal hernia. If signs of a tumor or exudation can be definitely made out, and the general symptoms indicate the formation of pus, then the patient should be etherized and the pus reached by incision, the pus evacuated, the cavity washed out and drained. If it is in, or involves the tubes and ovaries, the abdomen should be opened, and if the tube or tubes are occluded and pus found, they, with the ovary or ovaries, should be removed. If the abscess is around the appendix vermiformis or cæcum, an incision should be made near the crest of the ilium and the peritoneum dissected up till a place is reached where the peritoneum is adherent to the tumor, which should then be carefully opened, the pus evacuated, the sac washed out, and drainage-tube introduced without opening into the free cavity of the peritoneum. If it is about the gall-bladder, if the signs of pus can be made out, an incision over the sac should be made and the pus evacuated.

If the general symptoms are severe and no localized centre of pus made out, then an incision should be made in the median line and the peritoneal cavity explored with the index finger. If then a pus-sac is found, if it be so situated that it can be reached by another lateral incision and the pus evacuated without allowing the pus to escape into the free peritoneal cavity, it should be made, and the median incision closed. If it cannot be reached by a lateral incision where the wall of the sac is adherent to the abdominal wall, then the pus should be drawn off from the sac by an aspirator or trocar, and the cavity washed out clean with an antiseptic solution before it is freely opened, and a drainage-tube inserted.

If signs of general peritonitis show themselves, that is by vomiting, obstinate constipation, tympanites, etc., then a free incision should be at once made in the median line and the starting-point of the peritonitis found if possible. If it is over the cæcum an incision should be made over it, and the pus washed out by means of hot water of a temperature of 110° to 115° F., run from a large fountain syringe with a large-sized glass drainage-tube attached to the rubber. After the free pus about the cæcum is well washed out, several fingers, or the whole hand should be put in the abdominal cavity and the intestinal adhesions broken up, and all puddles of pus completely washed out. Then a glass drainage-tube should be introduced into each opening and the wounds closed around them, etc.

In pelvic peritonitis, as a rule, the operation is not necessary to save life; but it may be, and it is better to operate during the first attack, if there are symptoms plainly indicating the formation of pus, for the adhesions are much more easily broken up, and more complete removal of the diseased organ can be done than after contraction and dense adhesions have formed, as they do after repeated attacks of inflammation. Besides, dangerous pelvic abscesses are avoided and the bad influence of chronic invalidism are prevented. Of course, I refer to severe cases of local peritonitis, where there are symptoms either subjective or objective, indicating beyond reasonable doubt the presence of pus.

In typhlitis the operation should be done before the fourth day, the earlier the better, so as to prevent the chance of rupture and septic general peritonitis, which is, as a rule, attended by so much shock that no operation can do any good. As a rule, general peritonitis from rupture of a septic abscess is likely to be attended with more shock and rapid failure, and death, than peritonitis from direct perforation.

In all cases of general peritonitis an exploratory incision should be made as early as possible, after trying to lessen the tympanites. If an exploratory operation does no good, it is not likely to add much to the danger.

There may be cases of idiopathic peritonitis, but I have never seen one proved by anything to be relied upon. Certainly in septic peritonitis, where shock is not too great, free opening, washing out, and drainage will cure some cases. It helps, if it does not cure, tubercular peritonitis, and exploratory incision has proved to be, in the hands of experts, almost entirely free from danger, and it must become the practice in almost all cases of general and severe cases of local peritonitis where there are marked symptoms of the formation of pus, an extension into a septic peritonitis, or intestinal obstruction. Many cases of local peritonitis due to salpingitis may never necessitate a laparotomy, for they often become encysted, and give comparatively little trouble. Not infrequently the symptoms due to a severe metritis, where the peritoneum covering the enlarged and inflamed uterus becomes so sensitive as to give in a marked degree almost all of the symptoms of a peritonitis due to salpingitis, and repeated attacks of this kind are often mistaken by good physicians for genuine cases of salpingitis. But I am referring here to cases where a distinct tumor can be felt in the broad ligaments, accompanied by other symptoms indicating the formation of pus, which, when not operated on, rarely fails to cause a general peritonitis, and kills or makes the patient a confirmed invalid.

In typhlitis the diagnosis is, as a rule, comparatively easily made, and I believe it will soon become the general practice to operate early in all well-marked cases.

What I wish to especially advocate to-night is early operation in cases of general peritonitis, both those starting from a local peritonitis and those due to the escape of septic matter into the peritoneum, and to make it plain that to succeed in such cases it will not do to merely open the belly, allow pus to escape, put in a drainage-tube or gauge, and leave intestinal adhesions causing obstruction to remain to kill even more certainly than septic poison, or fail to empty and wash out all puddles of septic fluid encysted among the coils of intestines; but we must make free incisions large enough to introduce the hand, to break up all adherent intestines, and freely wash the whole cavity of the peritoneum and put in two or more drainage-tubes. Without question, many cases where the patients are debilitated weeks before the starting of the peritonitis, and in those cases where the septic poison is too virulent to be successfully washed out, our patient will die in spite of an early operation. But are the chances of this class of cases getting well lessened by the operation? I think not. Death may be hastened, but that is all. But the majority—the large majority—of cases of general peritonitis taken early are not in this desperate condition, and yet, if not operated on, at least four out of five die. Probably many of you may think that the two cases of general peritonitis that I have just reported were mild cases, and some will think that they would have recovered had no operation been performed; but recollect that one was operated upon only a few hours after the septic abscess had ruptured, and the other within seventy-two hours after the not so septic contents of his intestines had escaped into the peritoneal cavity. I did not wait till they were in a desperate condition, but they had every symptom of general peritonitis, and, had you been present and seen in the cavity of the peritoneum as I did, the amount of pus and of lymph breaking down into pus, and the condition of the intestines, you would not doubt my statement. The second case had complete intestinal obstruction, and the characteristic spinach green vomit.

THE MINERAL WATERS OF AIX-LES-BAINS AND MARLIOZ—PRACTICAL CONSIDERATIONS ON THEIR ACTION AND APPLICATION.[1]

By L. BLANC, M.D.,

AIX-LES-BAINS, FRANCE.

THE town of Aix-les-Bains is situated in one of the most picturesque alpine valleys, on the border of Lake Bourget, and surrounded by mountains which shelter it from north and east winds. The climate is mild, the average temperature being 55° F., and the vegetation nearly the same as that of the south of France.

The medical history of the town is of ancient origin, for, besides the temple of Diana, the arch of Campanus, the Roman baths and monuments which still exist, traces of numerous baths, swimming baths, and Latin inscriptions have been found in digging for the foundation of the new baths; all of which tends to show that under the Roman government the thermal establishment was highly important.

At present the bathing establishment is one of the most important in Europe. It is situated in the eastern part of the town, at an altitude of seven hundred and eighty-six feet above the level of the sea, and on a hillside, and is divided into three successive stories or terraces, which have been utilized for the application of the waters.

There are fifty-one douche-chambers where the douche is given by one or two persons, called *doucheurs* or *doucheuses*, two needle douches, three local douches, four vapor local douches called *douches Bertholet*, two vapor boxes for the whole body, sixteen vapor baths called *bouillon*, ten of them attached to douche divisions and supplied with natural vapor coming from the springs, forty-eight bath-rooms, ten of which adjoin douche-rooms, six swimming baths, two of them especially for children, and one reserved for skin complaints. There are two inhaling-rooms, one of which is provided with contrivances, called *tambours* and india-rubber tubes, to convey vapor to the lungs, eyes, ears, process termed *humage*, four foot baths, and three free drinking fountains.

Each douche is provided with numerous apparatus, of which the most remarkable is the mixing box, *boîte de mélange*, arranged so as to distribute the water during the douche at an unvarying temperature and pressure.

The douches bear various names, and vary in nature. Some are supplied with hot water only, some with hot and cold water, some with the two hot springs and cold water combined. The ventilation varies according to the douche. The pressure of the water varies from eighteen feet to forty-two feet.

In fact, the physician has at his command all the advantages of varied apparatus, temperature, ventilation, and pressure, which enable him to modify at will physiological results and to guide his patients through the course of treatment, thus avoiding mishaps which might occur in any establishment not so well fitted up.

Added to so complete a system of douches with natural hot mineral water, is the massage (shampooing), which is performed with rare skill by doucheurs who each year are specially instructed in the art, both in theory and in practice.

The massage, owing to the immense quantity of water to be had at will, is done with the aid of a continuous flow of water which gives to the *Aix-douche* its special feature. But, to understand well, it is necessary to give an exact description of the douche.

This is how it is administered: The bather being seated on a chair, the water falls on all parts of his body successively, with more or less force or volume, according to the prescription of the physician. Two doucheurs during this time rub the skin, shampoo (or *massent*) all the muscles, and make him move his different joints in every direction. This operation, which lasts from five to fifteen minutes, being over, the bather is wrapped in a flannel gown, sheet, and blanket. Once in this *maillot*, as it is called, he is placed in a sedan chair, conveyed to his house, where a warm bed awaits him, and there is confided to the *sécheur* of the house, who wipes him down, leaves him more or less time in the *maillot*, and gives him some mineral water, or other beverage to drink, according to the directions of his doctor.

By this manner of administering the douche, it is seen that the attentions with which the bathers are surrounded at the establishment are continued in their residences.

At other times, after the douche the bather, well dried and wiped, takes a walk, and brings on the reaction by exercise.

This douche may be infinitely varied with regard to the massage, the temperature, the volume of the waters, or the force and direction of the fall. The massage may be exercised partially, or on the back of the body in general, the head excepted; it may be more or less energetic; it may be accompanied by friction with the hands, or by brushes.

As regards the temperature, the douches may be taken from 61° to 116° F. The bather may pass insensibly from one degree to the other, as he may pass abruptly from an elevated to a low temperature, and *vice versa* (*douche écossaise*).

He may also be subjected to different temperatures at once. He may receive, for instance, hot water on the feet, tepid on the shoulders, and cold on the head. The bather may receive water on all the body, in torrents or in feeble quantities. This water may fall with force in jets, in sprinkling, or in streams; it may be conveyed by pipes furnished with tubes having larger or smaller openings, or terminated by a sprinkling-rose with holes more or less fine.

It may be directed horizontally to the hip, or douches

[1] Address delivered at a meeting of the Academy of Medicine, in New York, on Thursday, January 2, 1890.

may come from below upward to the perineum (*bec de corbin*), or vertically, that is to say, in any direction.

Finally, the pressure of the water may be varied infinitely, as I have shown above.

From this variety in the administration of the douches arises the action which I call mechanical, and by which we may produce physiological effects, sometimes stimulating, sometimes sedative, sometimes disturbing, at others revulsive—in a word, which can be modified infinitely.

Two thermal sources supply these douches, vapor baths, etc., one called sulphur, the other alum (though containing no alum), to the great amount of nearly one million of gallons in twenty-four hours, to which are added half a million of gallons of plain cold water.

Both springs are sulphurous, and contain sulphuretted hydrogen in equal quantities, besides several other elements, such as carbonate of iron, carbonate of magnesia, lithia, etc. There is an organic matter called *glairine*, which makes the water very soft, and is a great help for good massage. The temperature varies from 112° to 116° F. (they mark 4° by the sulphydrometer Dupasquier).

There are one hundred and ninety-two men and women employed in this extensive and important establishment, eighty four of them being masseurs or masseuses.

A variety of physiological effects are produced at the same time, through so thorough and so varied a treatment. Besides the special action of the water itself, well known as most beneficial in cases of rheumatism and gout long before the introduction of the present forms of apparatus, results of a very different nature are obtained by the combined action of the douche with massage, such as an exciting, a sedative, or a revulsive effect; but the principal one is the regulating of the organic functions, such as the circulation of the blood, and the appetite. By this means we remove the morbid conditions which are the chief causes of the two principal diseases for the cure, or benefit, of which Aix is famed, viz., rheumatism and gout. In a word, more or less of uric acid is eliminated as long as the treatment lasts, as has been proved by the works of Dr. Monard and Dr. Forestier.

The mechanical action of the massage and physiological movements in water or in vapor accounts for the successful results obtained in diseases of the joints, whether constitutional—hydrarthrosis, arthritis, etc., or arising from an accident or after an operation—contusion, fracture, wounds, dislocation, etc.

In these affections medical intervention is indispensable to direct the doucheurs in the operations; the *massages*, the movements especially, must be watched with greatest attention. It is for these reasons that the physicians at Aix are accustomed to stay in the bath establishment from 6 to 11 A.M. every day.

Though not mineral to a high degree, the waters of Aix, with help of those of Châlles, and particularly of Marlioz, which forms part of Aix, are made use of in catarrhal complaints, in those of the lungs, and also in skin diseases which require strong sulphurous thermal treatment.

The hydro-therapeutic treatment of Aix (douches and swimming baths, together with drinking the water of Marlioz, which are highly charged with iodine and sulphur, as well as breathing the vapor arising from these waters) forms a potent cure for children suffering from bronchial swellings, or from repeated bronchitis, which lays so ready a basis for consumption.

It also triumphs over syphilis or disorders arising from mercurial poisoning. In a work published in 1887, I have laid down in a precise manner the indications for the use of sulphur in the treatment of syphilis. The conclusions at which I arrived are the following:

1. Sulphur and sulphurous combinations do not themselves cure syphilis, but they have an incontestable influence on the complications of this disorder.

2. By their stimulating action they draw to the skin the syphilitic manifestations, and consequently facilitate the diagnosis and direct the physician in his therapeutics. They act on the organism during a course of mercurial treatment in many ways, by carrying the medicaments to the parts where the evil exists, that is to say, by producing the elimination of the mercury through the skin, by opposing the mercurial accumulation, and consequently the accidents which spring from it, diarrhœa, stomatitis, cachexia, and curing them when they have been produced.

3. By the cutaneous irritation which they produce, the sulphurous combinations have many effects. They accelerate the circulation of the blood and lymph, especially when scrofula is at work; thus they dissipate the ganglionic obstruction, and in fact they promote the reconstitution of the blood.

4. If such patients have rheumatic or gouty symptoms, syphilis and the other constitutional disease can be cured together.

It would take too much time to repeat here the experiments I made; at this time a summary will suffice.

If we pour a solution of hyposulphite or sulphite of sodium on a precipitate of albuminate of mercury, this precipitate is invariably dissolved.

The same phenomena take place in the human body.

In presence of alkaline salts and oxygen, the sulphur absorbed is transformed in the blood into hyposulphite and sulphite, which, when brought into contact with the albuminate of mercury fixed in the body, dissolve it and facilitate its elimination. I have taken, in fact, two classes of patients, whose urine I have examined every two or three days for a period of twenty days:

1. Patients undergoing at the same time the thermal and mercurial treatment. With these patients the results have always been positive, that is to say, mercury has always been found in the urine in an appreciable quantity.

2. Patients who have not taken mercury for one, two, or three months. I have examined the urine four or five days before commencing the sulphur treatment, and I have found no traces of mercury in the urine. I have afterward prescribed the sulphur treatment, *intra et extra*, and after a lapse of time varying from four to eight days, I have found with two-fifths of the patients treated mercury in the urine; which proved in a manner absolutely certain that mercury had accumulated in the body, and that this mercury was eliminated under the influence of the thermal sulphur treatment.

Reviewing a series of 1,000 patients during five years, I find:

Rheumatism	453
Gout	94
Diseases of the joints	102
Sciatica	61
Pharyngitis, laryngitis, and bronchitis	59
Syphilis	48
Metritis	27
Neuralgia	12
Gastralgia, dyspepsia	13
Cutaneous complaints	23
Various nervous complaints, palsy	24
Old bruises and broken limbs	36
Myxœdema	4
Various—contraction of the tendons, paralysis, ozæna, phlegmasia alba dolens, glycosuria, lead-poisoning	33
	1,000

As it is easy to see, the more important diseases treated at Aix are *rheumatism* and diseases of the joints in all their forms, from simple rheumatoid pains to the most severe rheumatoid arthritis, as well as all the complications which form part of the maladies—neuralgia, sciatica, dyspepsia, gastralgia, pharyngeal, bronchial affections, and even cardiac complications.

In speaking of *gout*, I refer principally to chronic gout of the joints, but also to gout which manifests itself in cutaneous eruptions, and to those cases called suppressed gout, in which the circulation of the blood is low, and the manifestations of the gout itself very inactive.

In speaking of the treatment of rheumatoid arthritis, Dr. Garrod says that waters which have been found very beneficial in rheumatoid arthritis are those of Aix-les-

Bains, at which place the douche is a very important part of the treatment.

In another book, Sir Alfred Garrod says: "1. Reviewing the results in the very numerous cases sent by me during the last twenty or more years, I am strongly of opinion that more benefit has been derived from the treatment at Aix than would have been received at any other spa I am yet acquainted with 2. That in many diseases of the stomach, liver, bladder, etc., the value of several other courses would often exceed that of Aix-les-Bains. 3. That in rheumatoid arthritis—the rheumatic gout of old writers—the value of the Aix-les-Bains course far exceeds, according to my experience, that of any other known spa. 4. That in many other articular affections, such as gout and rheumatism, the Aix course is very valuable, but not to the same extent as in rheumatoid arthritis; and that an equal benefit may often be received from some other mineral water treatment."

As for the other diseases I have mentioned above, it is easy to understand the successful effect obtained by combining the mineral waters of Aix-les-Bains and Marlioz; the temperature of the waters and the various manners in which the process of douching is performed, the varied and powerful system of hydro-therapeutics made use of, produce the therapeutical and physiological results above mentioned.

The establishment is open all the year round, but the most favorable time for undergoing a course of treatment is from May until the end of October.

I must add that the town of Aix-les-Bains, apart from the spring, is a healthy resort. The mildness of the climate, the varied excursions which can be made on the mountains, lake, etc., and the distractions found in the town, form useful agents in the cure of many ailments.

The waters of Marlioz, to which I have several times referred, are situated half a mile only from Aix, and contain sulphur, iodine, and bromine, and several alkaline salts. The bath establishment of Marlioz contains two large inhaling-rooms, nine bath-rooms, eight complete apparatus for atomized spray inhalation, a cold douche, four hip douches (*douche de siège*), two ascending douches, and two drinking fountains.

The alkaline waters of St. Simon, which are about equally near, can well replace the waters of Contrexeville, Vitel, and Evian, in the treatment of kidney diseases.

THE PHYSIOLOGICAL TREATMENT OF OBESITY.[1]

By WALTER MENDELSON, M.D.,

NEW YORK.

The practice of medicine is—even at its best—so empirical an art, the limitations of our best endeavors, when measured by our aspirations, are everywhere so narrow, that we should always be prepared to hail with joy any one department in which we discern *some* prospect of advancing with anything like scientific accuracy.

Though pharmacology has made great strides in the past decade, though we are well acquainted with the physiological action, and even with the therapeutic value, of drugs; yet, compared with the vast amount of labor already expended, how small, on the whole, is our success in combating disease by pharmaceutical agents.

I have selected *Obesity* as a topic for discussion to-night, because it seems to me that it is a subject upon which some definite and accurate knowledge is already at hand. Knowledge which may be called scientific, because, if the necessary conditions which it imposes be fulfilled, it will enable us to predict what will happen with a certain and, indeed, not inconsiderable, degree of success.

Physiological chemistry—great as are the triumphs already achieved—is still in its infancy. And while much that we now think we know regarding the processes of nutrition and of waste, will, in the future, be revised or even cast aside, yet sufficient data regarding obesity seem to have been now obtained to justify a basis of action.

In order to gain an intelligent insight into the nature of obesity, it is necessary to have, at least, a general idea of the laws relating to the processes of nutrition.

The body has often been likened to a machine. The food being the fuel, whose consumption becomes manifest in the liberation of energy—of work. But with this difference: that in the body the food is not only the source of energy, but that it also replaces the tissues which are necessarily consumed during the expression of this energy.

Hence, while in the machine, only one kind of food—fuel—is needed, whose oxidation produces heat, and that, motion; for the body, foods are needed which not only serve the purpose of liberating energy by being oxidized, but which also are capable of being transformed into integral parts of the constantly wasting, and constantly growing bodily machine itself. Consequently, we may distinguish two kinds of foods—or rather, two functionally different foods—"fuel foods" and "tissue foods."

Of the chemical changes going on in the body, it may be said that they consist in general of decompositions and oxidations. In consequence of these processes relatively complex, slightly oxidized, and hence unstable compounds are converted into relatively simple, highly oxidized, and therefore stable bodies. For example: the relatively complex albuminous, saccharine, and fatty substances are changed mainly into the far simpler compounds, urea, water, and carbon dioxide.

And, concomitant with these changes of chemical form, we have latent energy liberated, whose freedom, becoming potentially manifest, expresses itself in all those various phenomena—muscular contractility, animal heat, nerve action, secretion—which, in their totality, make up that which we term Life.

The various articles which compose our dietary may be almost endlessly extended in number. Yet they can all be brought into one of three classes, namely: 1. Nitrogenous, albuminous, or proteid foods. 2. Carbohydrates, or starches and sugars. 3. Hydrocarbons, or fats.

Experience has shown that under ordinary circumstances, and in the temperate zone, health is best preserved when the diet consists of a combination of all three of these classes. No fixed amounts applicable to every person and to all conditions can be given regarding the absolute quantity to be ingested, for the measure of food required will vary as circumstances arise which require the expenditure of much or little energy. But it has been found that, on an average, 130 grams of albumin (equivalent to 1¼ pound of meat), 84 grams of fat (3 ounces), and 404 grams (13 ounces) of carbo-hydrates are consumed daily, and that the proportion of the albuminous to the non-albuminous foods ingested is about 1 to 3¼ or 4.

The study of the causes of the deposition of fat in the body is one of the earliest that engaged the labors of physiologists, our views having become modified with each increase of knowledge.

After Chevreul—who recently died a centenarian—showed, quite early in the century, that the same substances occur in the fats of animals and of plants, it was thought that deposition was the result of a mere transference from the plant to the body of the excess of fat taken in the food.

The studies of Liebig gradually modified this idea, and it was then believed that the body fat was formed directly from the starches and sugars ingested.

More recently, Pettenkofer and Voit have shown that the albumin of the food is at least the *principal* source of the fat formed in the body. The albumin of the food undergoes, after it has reached the cells of the tissues, certain chemical changes by which part of it is converted into fat, and part goes to the direct nutriment of the

[1] Read before the Section on Theory and Practice of Medicine of the New York Academy of Medicine, January 21, 1890.

tissue-cells. According to Voit[1], 51.5 grams of fat can be formed from 100 grams of albumin.

Many exact experiments have been made which prove this formation of fat from albumin. Thus, dogs fed on lean meat, and maggots on blood, accumulated considerable fat. A dog fed on lean meat and palm-oil, which contains no stearic acid, stored up fat having the usual amount of stearic acid normal to dog's fat.

The fatty degenerations of the organs following phosphorus poisoning, and the fatty condition of the uterus during involution, are familiar instances of fat being one of the decomposition products of albumin.

It is not, however, as though *all* fat were formed from albumin. A *certain amount* of that taken as food is undoubtedly stored up. But the increase of body fat occurring after eating much fat—though in part a direct result—is chiefly brought about indirectly, the food-fat shielding from oxidation that which has been formed from the albumin ingested.

Thus, when a dog is fed on meat and mutton suet, it gains in body fat. Not because the mutton suet is changed into dog's fat, or is deposited as suet, but because the more ready oxidation of the suet prevents the fat proper to the animal's tissues from being destroyed.

It is in the same indirect way that the carbohydrates act. Ordinarily the starches and sugars are not themselves converted into fat. Only when taken in abnormally large quantities does this seem to occur. But when taken as food, along with albumin, they, being more easily oxidizable than the tissue fat, by preventing the latter from being consumed, give rise to an accumulation.

To sum up—we see that there are three sources from which fat may be derived for the body: First, from that resulting from the splitting up of the albumin of the food; second, from the transfer of that fat ingested as food; and third, probably from fat formed from starches and sugars when these are taken in large quantities.

Now, having seen the sources from which the body manufactures its fat, it next remains to inquire into the conditions under which this fat tends to be hoarded up in the tissues of the economy.

Up to quite recent times it was the general belief that the oxygen taken into the blood from the inhaled air was the direct factor concerned in the many chemical decompositions going on in the body. And, in consonance with this view, it was held that fat accumulated from more of it being formed than the oxygen could consume; either excess of food-supply or deficiency of oxidation being ascribed as the causes of obesity.

But, alas! seductively simple as this hypothesis appeared, and satisfactorily as it seemed to account for many of the conditions whose existence it was called upon to explain, it has had—like so many plausible explanations—to be relegated to the limbo of errors. It is but another example of the observation to which all of us must have been often led, namely, that the most obvious and plausible explanations of natural phenomena are also almost invariably incorrect. Indirection seems to be a basic principle in the operation of natural law—evolution furnishing its most magnificent example.

Following on the lines first laid down by Rudolf Virchow, that the cell is the somatic unit, we now know that all the metabolic phenomena of the economy have their seat in the cells—that all cells have inherent in them the power of splitting up relatively complex chemical compounds into bodies of simpler composition. And while we are as yet unaware of the processes by which the cell effects these decompositions, we *do* know that the oxygen in the tissues is but indirectly concerned in them. The body being but an aggregation of cells, other things being equal, the more cells an organism contains, the greater will be the amount of chemical change performed.

Certain external agencies have the power of modifying the chemical powers of the cells. Among those that diminish may be instanced quinine, alcohol, morphine, low temperature, and deficient food-supply (including oxygen), while excess of food-supply, the changes consequent to fever, high temperature, and muscular activity increase them.

Now, the disintegrability of the different classes of foods brought to the cells varies widely. And the causes of obesity, and its treatment on physiological grounds, can only be fully understood when these differences are known and given their due value.

Experiments have shown that of the three great classes of food—the proteids, the carbohydrates, and the hydrocarbons—the one most easily split up is that of the proteids. The carbohydrates are next in ease of decomposition, while the fats are most resistant.

If proteid food alone be ingested, the soluble albumin carried to the cells is there, in part, converted into the tissue-albumin of the organ formed of the cells, and in part changed into fat and other products. All of which will tend to be split up into still simpler bodies till the power of the cells becomes exhausted.

If now, in addition to proteids, fat be ingested, the decomposition of the proteids will go on as before, but the food-fat, being more readily oxidizable than the tissue-fat formed from the proteids, will shield the tissue-fat from destruction, and, at the same time, preserve the tissue-albumin from destruction as well.

Thus indirectly, and in a double way, the food fat leads to a storing up of fat. Firstly, by affording a more easily oxidizable substance for the liberation of energy than tissue-fat; and secondly, by preserving the tissue-albumin from destruction there results greater chemical activity of the cells, more active elaboration of the food-albumin, and, as a result, both increased growth of the cells and increased manufacture and storage of the fat made from the albumin brought to them.

An analogous process obtains when the carbohydrates, in their soluble form of glucose, are fed to the cells together with albumin. The sugar is more easily decomposed than the fat, and may, if present in sufficient quantities, so absorb the energies of the cells as to shield the cells and the fat from destruction, and thus give rise to an accumulation of the latter.

Rubner, working in Voit's laboratory, has determined that the following quantities of the food classes are equivalents—are *isodynamic*, as Voit terms it—that is, that in their decomposition into carbonic acid and water each yields an equal quantity of energy measured as heat:

Fat	100 grams.
Albumin	211 "
Starch	232 "
Cane-sugar	234 "
Glucose	256 "

Now, it will be apparent, from an examination of this table, that an accumulation of fat will most readily occur when the diet contains an overplus of fat; because, while least in quantity, fat has the highest equivalent—next, when containing an overplus of albumin; and next of carbohydrates.

Suppose an individual required per day, to keep his fat and flesh unchanged,[1] 118 grams of albumin, and 259 grams of fat; 118 grams of albumin, being equal to 18 ounces of meat.

Were he to take albumin alone, he would require, per day, 664 grams of albumin to retain a constant weight. This amount represents six pounds of meat per day, a quantity impossible to consume, the intestinal canal being unequal to the task of digesting and absorbing so large an amount.

Were he still to take the original 118 grams of albumin, and exclude all fat, 600 grams—or 1¼ pound—of starch would have to be taken at the same time.

On a mixed diet of all three classes of food, he would

[1] Voit: Ursachen der Fettablagerung. München, 1884.

[1] Voit: Ursachen der Fettablagerung. München, 1884.

take: 118 grams of albumin, 100 grams of fat, and 368 grams of starch.

Any excess in any one of these three classes—supposing, of course, that the mode of life remains unchanged—must lead to an accumulation of fat in the body.

Now, ordinarily of course, no man habitually eats meals composed either of any one, or even of any two of these food classes. But his diet will consist of the usual combination of all three. And while, therefore, it could hardly happen that an overplus of fat would form even were an individual confined to any two of these classes—for lack of appetite from too monotonous a diet would prevent it, if nothing else did—it can very well happen that on a mixed diet containing plenty of fat and starches, a little more albumin than is needed to maintain the equilibrium of flesh and fat, may be ingested.

And it is the fat formed in the cells from this surplus albumin which—since it is protected from oxidation by the food-fat and starches—accumulates little by little in the tissues, and gradually leads to obesity.

A man need not necessarily be a glutton to grow stout. It is the slight excess that may daily be taken in the food, which by a gradual increment stores up the fat in the tissues. Nor would even this be sufficient in all individuals. Certain contributory causes often exert a powerful influence in the genesis of obesity, and when these, from any reason, come into play an individual may grow fat, though, as he will tell you, he eats even less than formerly.

Anything which lowers the oxidizing powers of the cells will have this effect, such as free use of alcohol; lack of exercise; living in close, hot rooms; a diet whose insufficiency in albumin lowers the vital powers of the cells; various pathological conditions, such as heart disease and other causes of impaired circulation; chlorosis, etc.

And then—and to this cause the most marked cases of obesity are certainly chiefly due—we must not forget that some individuals have a predisposition, seemingly inborn and often inherited, to grow fat.

It is a fault of the cells, analogous to those aberrations which in some persons produce more uric acid than is normal, which in others lead to glycosuria and diabetes, and in others again to the production of cystin. Other individuals, no matter how much they may eat and how little they may exercise, never grow fat.

These same peculiarities show themselves in animals as well as in man. Who ever saw a fat greyhound, or a lean pug-dog?

Hence in treating obesity the individuality of the patient must be kept well in mind. In general, we are inclined to associate with fatness a certain indolence of mind as well as of body, an inclination to be unenergetic and phlegmatic—as Prince Henry says to Falstaff: "Thou art so fat-witted with drinking of old sack, and unbuttoning thee after supper, and sleeping upon benches after noon." And yet it may well be questioned whether these qualities are not the effect rather than the cause, of obesity. Many instances might be cited of stout men being the contrary in disposition. Two of the most shining examples of intellectual industry and acumen that now occur to me were very stout men, Gibbon and Buckle.

Nevertheless, we are inclined to associate leanness with a nervous, keen, and intellectual temperament; activity of mind seemingly going most often with a condition allowing of activity of body. Shakespeare illustrates this popular feeling when he lets Cæsar say to Antony:

> "Let me have men about me that are fat;
> Sleek-headed men, and such as sleep o' nights:
> Yond' Cassius has a lean and hungry look;
> He thinks too much: such men are dangerous."

Having now reviewed the chief factors concerned in the manufacture and deposition of fat in the body, the means to be adopted for preventing an accumulation will have become evident.

Our aim must be to make the production not exceed the consumption, and where a surplus exists, consumption must for a time exceed production.

In the great majority of cases (in spite of the protestations of fat people to the contrary), ingestion of too great a quantity, or of an improper quality, of food, often combined with too little exercise, is the cause of obesity.

It remains therefore for us to suitably regulate the diet and exercise; bearing in mind that the change we wish to bring about, to be beneficent, must be gradual; that the cells must be educated by degrees to the new duties we wish them to perform; that anything approaching starvation—like the Banting cure—is to be condemned.

With regard to diet, it must be our general plan to give much albumin, and relatively little non-nitrogenous food. And we do this in order, firstly, that the cells, from the abundance of nourishment brought to them, shall be capable of great chemical activity; and, secondly, that the tissue-fat thus necessarily formed shall not be preserved from oxidation by the presence of the more readily oxidizable food-fat and starches.

But we must always keep in mind that, as the fat of the body becomes by this process gradually reduced, the diet must undergo a corresponding change, more and more of the non-nitrogenous foods being allowed as the body grows relatively richer in albumin and poorer in fat. For, unless this be done a point will be reached where not only the fat of the body, but the albumin as well, will be consumed, and the patient, after feeding thus on his own muscular and glandular tissues, will begin to complain of weakness and lassitude.

This is the error of the Banting cure, prescribed to Banting by Dr. Harvey, of London. Banting himself states that he had to discontinue treatment every little while, in order to regain strength. The Banting diet prescribes enormous quantities of albumin, with an almost total exclusion of fats and carbo-hydrates. As before stated, it is impossible for a human being to take sufficient meat, eggs, etc., to cover the destruction of fat necessarily occurring, hence the muscular tissues soon begin to waste as well.

Voit gives the following quantities as required for nourishment without the accumulation of fat:

	Albumin.	Fat.	Carbohydrates.	Fat equivalent.
For a hearty workman....	118	56	500	678
" well-to-do doctor...	127	89	362	576

And Oertel[1], who has, as you know, given the subject the closest of study, gives the following minimum and maximum amounts per day for reducing fat:

	Albumin.	Fat.	Carbohydrates.	Fat equivalent.
Minimum.....	156	22	72	127
Maximum.....	170	44	114	173

In accordance with these figures he has prepared two diet lists. And the following diet list is one that I have made up as an average of his two, and also somewhat modified for American habits. But I must beg of you to bear in mind that such a list is only to serve as a *general guide* to the patient to whom it is to be given. No absolutely hard-and-fast rules can be laid down, and patients under treatment should be seen—and weighed—from time to time; increasing one kind of food and diminishing another as occasion demands.

Diet List for Reducing Fat.—*Breakfast:* 1 cup (6 ozs.) tea or coffee, with milk and sugar. Bread, 2½ ozs. (2 or 3 slices). Butter, ½ oz. 1 egg or 1½ oz. meat.

Dinner: Meat or fish, 7 ozs. Green vegetables, 2 ozs. (spinach, cabbage, string beans, asparagus, tomatoes, beet tops, etc.). Farinaceous dishes, 3½ ozs. (potatoes, rice, hominy, maccaroni, etc.), or these may be omitted and a corresponding amount of green vegetables substituted. Salad, with plain dressing, 1 oz. Fruit, 3½ ozs. Water, sparingly.

Supper or *Lunch:* 2 eggs, or lean meat, 5 ozs. Salad (radishes, pickles, etc.), ¾ oz. Bread, ¾ oz. (1 slice). Fruit, 3½ ozs. Or fruit may be omitted and bread, 2

[1] M. J. Oertel: Kreislaufs-Storungen. Leiprig. 1885.

ozs., substituted. Fluids (tea, coffee, etc.), 8 ozs. No beer, ale, cider, champagne, sweet wines, and spirits. Claret and hock in great moderation. Milk, except as an addition to tea or coffee, only occasionally. Eat no rich gravies, and nothing fried.

Remember that your patients should always feel *better* —never worse—under treatment. That lassitude and fatigue are signs that the muscular tissue, as well as the fat, is being reduced, and that more non-nitrogenous food must then be allowed.

Above all, never yield to the wishes of the patient to grow thin *quickly*. All reforms, to be lasting and beneficial, must be slow in action, they must be the result of education, they must be a growth from within, not an impress from without. And the cells of the body, in their infinite diversity of occupation resembling the citizens of a state, can by slow degrees be habituated to better things, to change their vicious mode of action to one harmonious with the welfare of the commonwealth. And when this education has once been established, continuance becomes a mere habit.

In all that has been said, no allusion has been made to that form of obesity connected with heart disease. I have preferred to confine myself in this paper to the pure, uncomplicated type, hoping, perhaps, that in the discussion that may follow, this phase of the subject may be dealt with.

In conclusion, let me say that the ideas underlying this sketch of the physiological basis of the treatment of obesity have been taken from the writings of Voit, of Oertel, of Munk and Uffelmann, of Ebstein, and of others.

NEUROTIC TUMORS OF THE BREAST.[1]

By E. P. FOWLER, M.D.,

NEW YORK.

In 1865 a case came under my professional care, the incidental outcome of which fixed my attention upon a variety of malady that before was unknown to me. The disease consists of mammary tumors, apparently dependent upon uterine or ovarian conditions, inasmuch as they seem to be curable by treatment of the womb and its belongings. The matter will best be put, perhaps, by the description, the treatment, and results of seven cases, the records of which I have preserved.

Case I.—J. M. S——, record of 1865. The subject was a girl, aged twenty-two, above average height, slight in person, most profuse auburn hair, large, dark eyes, almost black eyebrows and eyelashes, very full lips, Grecian style of profile, and high color. Her natural abilities intellectually were decidedly above the ordinary, her emotional nature extreme. She seemed to be a natural religious devotee, and since a broken love affair, some two years before, almost a religious monomaniac. At various times the girl had been the subject of hysteria. The father, and several in his family, were epileptics of a mild form, but they generally were endowed with unusual mental brilliancy. Menstruation had been quite irregular with the patient, the intervals varying from two weeks to two or three months; always free and always painless, excepting an invariable discomfort—hardly a pain—in the left breast and a soreness in the right one. The patient described a pain in the region of the ovaries, as a "never-ending" one. In the left breast, above and to the outside of the nipple, there was an ovoid body, apparently about two inches in diameter by three in length. It was quite hard, and seemingly without attachments.

On examination much complaint was made of exquisite pain, which was greater when the touch was slight than when firm; this symptom was so marked, that satisfactory examination could not be effected until the subject was so placed as to be unable to draw away. With all this tenderness to conscious touch it was plain to be seen that the dress worn by the girl was very close-fitting. I examined the axilla for glandular enlargements, and while so doing observed that the pressure of my wrist, which her clothing compelled to rest somewhat heavily on the tumor in the breast, was not complained of. She stated that the examination gave pain in the axilla, yet there was no swelling whatever of the glands, nor did I find glandular enlargements in any other part of the body.

Upon inspecting the abdomen the entire surface was hyperæsthetic, notably in the left ovarian region. A light pressure was more complained of than a firm one. Upon increasing the pressure to see how far it would be tolerated, the patient requested a continuance of it, saying that it gave an indescribable sensation of both pain and pleasure. In a few moments she fell into what seemed a deep sleep, only that the commencement of the state was accompanied by irregular respiration, and peculiar facial and bodily movements; these soon subsided, and then the sleep resembled that heavy stupor so often the sequel of epileptic attacks, and for the space, I should judge, of about a half-hour, it was impossible by any means to arouse her. The event gave me a genuine surprise, and for the time no small anxiety, and the mother, who accompanied the daughter, was thoroughly alarmed. Further examination of the case was postponed for two days.

On the second interview, this time at the patient's house, I could by digital examination find nothing out of the normal with either vagina or womb. The womb seemed a little under-sized perhaps, but the difference was not greater than is to be observed in the feet, hands, nose, ears, or any part of the body of different persons. After completing my examination, I again applied firm pressure over the left ovary, keeping a strict time-record of the experiment. At the expiration of a little more than three minutes, the same condition before described came on, the sleep or stupor lasting a little over twenty-five minutes.

The case had already been examined by five different eminent medical men, who were united in the opinion that the tumor should be removed without delay. These concurring opinions and the social standing of the patient made it most necessary, for my own reputation and welfare, that I should give no hasty counsel, and therefore I arranged for another visit, three days later.

After careful thought and industrious search in literature for similar cases I had concluded to substantially concur with the advice already obtained, but when the interview came about I had no opportunity to express my opinion, before the mother rather overwhelmed me with enthusiasm over the unexpected success of my "treatment." I was naturally somewhat puzzled (as I had given no treatment), until I soon comprehended that the vaginal examination had been construed as a "treatment." The girl looked much changed for the better, and averred that the tenderness of the breast and the lower part of the abdomen was decidedly less, and both she and her mother were positive that the tumor was smaller.

I suppose that imagination was doing very much toward finding that which was desired, but examination discovered to me that they were right and that the lump was notably decreased. I had not the slightest supposition that my examination was in any way related to the change, but I could not for the moment muster the moral courage to destroy their happiness and hope by bluntly saying, what I thought, an operation would eventually be necessary. They were urgent that another "treatment" should be made, and as the tumor had decreased, brief expectant treatment seemed justifiable; so I made another examination. This time the digital contact with the uterus produced the same train of phenomena as pressure upon the left ovarian region did before.

The case was under my care between two and three months, visits were made once or twice a week, and the only treatment in any way was a repetition of the vaginal examination. The attending phenomena which I have

[1] Read before the New York Neurological Society, Tuesday, January 7, 1890.

described became less and less; of the tumor, at the end of ten weeks there was not a trace, there was no pain or tenderness in the ovarian region, no hyperæsthesia—in short, nothing abnormal of any kind.

I do not think my experiments produced true sexual orgasm, though they were certainly quite kindred. For a real orgasm the process was too long, though the respiration, the facial and bodily movements were suggestive. During the treatment I discovered that pressure between the upper cervical vertebræ would produce all the described symptoms, though in a lesser degree.

The recovery was permanent. About four years after the lady married, has since had four children; her health is, and has been, generally good. She nurses all her children, who are very healthy specimens, and mother and all are still living.

Case II.—A. N. McC——, a married woman, aged thirty-one, profuse dark-red hair, darker eyebrows, eyes very dark, complexion pale, medium height, and very slight. She strongly resembled her mother, and like her was very hysterical.

She came under my care in 1858, the first year of her married life. Between eleven and twelve years after that she became a widow, never, to her great sorrow, having been enceinte. She had become a resident of Charleston, S. C., when in 1870 she discovered a lump in the left breast which, within the space of seven or eight months, grew to nearly twice the size of a hen's egg, very movable, hard, and sensitive. In 1871 she came on to consult me, but arrived just after I had left for Europe. She took the advice, in turn, of three of the most eminent authorities to be found in New York, each of whom counselled the immediate removal of the tumor. Like all women of similar temperament, she had a fetich-like faith in her regular medical attendant, and the only one who had ever been her regular medical adviser besides myself was Dr. Marion Sims. She at once set out for Europe, but on her way (in London, I think) she saw Dr. Sims, who advised and offered to operate. Declining for the time, she continued her travel, and met me at Vevey, Switzerland. I concurred in the opinion already given, that an operation would probably be necessary, and directed her after a rest to return to New York, in time to recruit there for a couple of weeks before my arrival. When I saw her, at the end of this time, the tumor had somewhat increased, the ovaries were tender, and I do not remember that I ever encountered another case where the cervix uteri seemed so intensely painful to touch, and yet with entire absence of ulceration, inflammation, or misplacement. An examination, less complete than desirable, so disturbed and prostrated the patient as to give me some anxiety, but, notwithstanding this, the improvement shown upon the following day was sufficiently marked to give the patient belief that I had righted some misplacement. The tenderness was so reduced as to permit upon this occasion a very thorough examination. Pressure upon the cervix of the uterus still gave much pain, but the patient said that even the pain seemed to afford a sense of relief. I advised a removal of the tumor in the breast, and even went so far as to make arrangements with a surgeon to perform the operation.

For certain reasons the operation was postponed to the end of three weeks. The second examination seemed to afford an additional relief similar to that experienced from the first one. It seemed evident that there was a benefit, and at the patient's urgent request I continued every second day the manipulation. In addition to the pressure before given, I each time gave the cervix a kind of massage of two or three minutes' duration, that is, a firm rubbing. By the end of twelve days the tenderness of the womb had entirely disappeared, excepting that kind of sensitiveness which is so common to its posterior surface. Along with this came another change, entirely unexpected, but marked and gratifying; the tumor in the breast had become also less sensitive, and to a very palpable degree lessened in size. The condition, entire, strongly recalled the case just described, and as toward the termination of the three weeks the tumor still continued to decrease, I advised a postponement of the intended operation, and continued the uterine massage with intervals of three days. The massage treatment was continued for about three months, though at steadily lengthened intervals.

For nine months, during which the patient was under my immediate care, she took no medicine whatever, unless now and then for a cold, and at the end of that time she left my care in better health than she had been for some years, and with not the slightest trace of the tumor. About eight months after she came to me again, in great trouble, as the tumor had somewhat recurred. The matter assumed a more complicated importance from the fact that she had become engaged to marry again, and she had scruples about fulfilling the engagement, at least without acquainting her intended husband with the entire facts of her case. The marriage was still some months off, so I advised her to remain silent and put her under the same management as before. At the expiration of three weeks the tumor had again disappeared, and treatment was suspended. One month after there were again indications of return. From some observations which I hardly need detail, and reflecting upon the case in all its various bearings, I concluded that marriage would provide all the requisites for a permanent cure, and as circumstances favored it I advised the event at an early date. The advice was followed and the result substantiated its soundness. The tumor never returned, and up to the time I last saw the patient, about one year since, her health had been invariably good. Nine years after her marriage her second husband died of South American fever, and two years later came the menopause, without any uncommon disturbance. She was never enceinte by either husband, though I could discover no reason why she should not conceive.

Case III.—L. C—— was in every respect more peculiar and interesting than the two already recited. She was the daughter of a book-dealer, eighteen years of age, rather tall, slight, gray eyes, most profuse dark-brown hair, very dark eyebrows and eyelashes, complexion clear and ruddy. The breasts were unusually developed, more noticeably as contrasted with her otherwise slight form. She matured at about thirteen, was always irregular in menstruation, which was accompanied by severe womb-colic and fits of hysteria. Some five months before she came under my care the patient had called the attention of her then physician to a lump in the right breast. He considered the thing serious, called counsel, and it was agreed that an operation was necessary, and it was thought also that a portion of the womb, which was found to be very hard, might require exsection. The girl was an only child, the family became greatly alarmed and she completely demoralized; she violently refused to submit to any operation, refused to leave the bed or to take nourishment, fell into extreme insomnia and intolerance of light or sound, and was disposed to reject food within ten or twenty minutes after it had been taken. Upon examination, as she came under my care, I found a tumor of, I should judge, about two inches diameter, nearly round in shape, situated just below and outside the nipple of the right breast. The milk-ducts in the vicinity of the tumor were all distended and hard. There were no glandular enlargements in any other part of the body. The vagina exhibited a decided hyperæsthesia, and in addition to this it possessed a most extraordinary power for contraction; it held the finger as firmly as though grasped by a hand, and in a few moments the womb itself—at first as soft as usual—would become erectile and with an almost bone-like consistency. This contractile stage lasted for three or four minutes, when, with a relaxation and limp condition of the entire body, the patient would sink into a profound sleep of several hours' duration, from which it was difficult to arouse her even to a partial degree. During this period there always was a strong odor, such as is often to be noticed during epileptic attacks. The respiration would average about fifteen, and the pulse about fifty, per

minute; at other times the respiration averaged about thirty-five and the pulse about eighty. I found that this induced sleep could at any time be effected by three or four minutes' (sometimes much less) firm pressure against the neck of the womb.

Since the time the operation had been advised continued natural sleep had rarely exceeded with her thirty minutes. When waking from this induced sleep she for a time yawned and stretched almost continually, and the craving for food was imperious, and almost any kind of food was taken with the utmost avidity, though at all other times—and at all times before the induced sleep had been chanced upon—the repugnance and resistance to nourishment was most serious, and it was very often rejected, something which never occurred after the meals following induced sleep. I did not tell the family so, but they inferred that the results of my uterine manipulations were from opiates which I had applied locally, and that the sleep was an opium-sleep. The two previous cases decided me to avoid all medicine in this instance, and see what could be done by a treatment similar to that pursued with the others.

During two weeks, treatment was given every day, at the end of which time there was a moderate appetite for three meals a day, which were generally retained. There was an average of over nine hours sleep in the twenty-four, four to six of which would uninterruptedly ensue after the treatment. At this point came menstruation—the first in three months—painless, and of four days duration. Three days after the menstrual cessation I resumed the treatment, now every other day. For a full week the induced sleep was neither as profound nor as restful as it had before been. The vaginal contraction and the uterine erectility, which had greatly decreased before the menstruation, had much returned, and in every way the situation seemed a little discouraging. Before the menstruation the milk-duct enlargements had entirely disappeared; now they were present, though less in size. In the tumor itself there had at no time been any change. Two weeks more of treatment and the sleep and appetite were regained, the swelling of the ducts had gone, the tenderness in the tumor subsided, the contractility of the vagina and erectility of the womb almost gone, the mind cheerful, and the entire disposition marvellously changed for the better. At this date and afterward the girl, at each time I saw her, averred that she often felt the tumor move, and her mother said that she had actually seen it do so, and with the hand felt it do so. I failed to chance upon any such occurrence. From this time, however, the tumor began, with varying rapidity, to decrease, until at the end of about seven months there was not a trace of it left.

The menstruation had become regular, painless, and without hysteria; sleep and appetite normal, and the weight had risen from one hundred and three to one hundred and twenty-seven pounds. The breasts were more natural in size, there was no degree of vaginal contraction or uterine erection remaining, and I dismissed the patient from my professional care.

A few months after this the young lady engaged to marry, and there were signs of the whole trouble recurring. I advised marriage at the earliest date practicable, and for the pending month I treated her as before, two or three times per week, under which the symptoms soon vanished.

After marriage she had no more trouble, she has had two living children and one stillborn; ten years have passed, and her health has been uniformly fair, with no return whatever of any trouble in the breast. There was no vaginismus at time of marriage.

Case IV.—A. M. S.—— was an unmarried woman, twenty-four years of age, about medium height, slight build, brown hair and eyes, eyebrows darker than hair, full lips, fully developed breasts, and hips large compared with waist. Complexion was pale. Menstruation occurred before the age of twelve, always irregular and painful, accompanied by severe paroxysms of hysteria. When about nineteen years of age she had an unfortunate love affair, through which her good health was seriously impaired. It was during this time that she discovered a small hard lump at the outer and lower edge of the left breast. In the course of twelve months this had come to the size of an English walnut, and at this time her mother brought her to see me. As in the other cases, I found the tumor very movable and very hard, and also an entire freedom from glandular swellings in any other part of the body. There was the same exquisite sensitiveness to a light touch, more or less over the whole body, but especially over the breasts and the lower abdomen. Firm pressure could be endured, though it caused pain, but a light pressure seemed to induce an uncontrollable nervousness. The neck of the womb was very hard, and the entrance to the canal consisted of a circular opening not more than three-sixteenths of an inch in diameter. My first step was to enlarge the canal, which occupied about three weeks, during which time I gave phosphate of iron and carefully regulated the diet. During this time the tumor increased, and the condition generally seemed to have gone on rather more unfavorably than it was reasonable to expect simply as a result of the operation.

I called a surgeon, who advised a month's building up and then a removal of the tumor. Accordingly tonics and a generous diet were followed and, in recollection of the other cases I have cited, I added to this twice a week a massage treatment of the cervix uteri. The treatment did not produce a stupor as in Case I., but within a short time after the patient would fall asleep and remain so for two or three hours, and wake with unusual sense of vigor and *bien-être* and intense craving for food. A good, hearty meal at such times never disagreed with her, though at other times she was liable to indigestion. Within ten days the patient was much improved in general health, and the tumor seemed a little less, and in the third week the reduction was unmistakable, and a steady continuance of reduction reversed the decision as to an operation. At the end of the third week menstruation ensued, was fair in quantity and quality, and without very severe pain, but for ten days the tumor showed a decided increase. The same course as before was pursued for the next three weeks, and indeed for three months, except when it was interrupted by menstruation, which came very regularly at twenty-four days interval, lasting about four or five days without much pain, and once without any. Just previous to the second menstruation the tumor was not larger than an olive; it was again somewhat enlarged by illness, but before the third time there was nothing that would have attracted notice had there been no previous trouble, and during that time there had been no disposition to hysteria.

From this on the patient continued in ordinary good health, only that now and then, at the catamenia, there would come reminiscences as it were, and at one time, during the existence of a short-lived and rather stormy love affair, there was a temporary return of hysteria and a slight reappearance of the tumor. These disappeared with the end of the love business, and for three years since the health has been in every way as good as befalls the average mortal.

Of Case V. I can only report progress. It came under my care about eighteen months ago, in the person of a young lady, aged twenty-seven, medium height, gray eyes, brown hair, and slight figure. General health only fair, menstruation irregular and painful, accompanied by paroxysms of hysteria. There was a considerable degree of insomnia, much tenderness of the upper and lower ends of the spine and over the ovarian regions, rather greater over the left than the right. Menstruation was nearly always accompanied by epistaxis, three or four spells a day. I was, however, consulted with special reference to a couple of lumps which had formed at the lower part of the left breast, one being nearly the size of

a small hen's egg, the other about one-half as large. As in the other cases, they were freely movable, very hard, and very tender only upon slight pressure; pretty snug corsets seemed to give no discomfort. There was no other glandular trouble elsewhere, unless, perhaps, a little enlarged liver.

The womb was anteverted, painful to the touch, and with an acid catarrhal discharge, but no vaginal leucorrhœa. I resorted to injections of hydrastis and the use internally of actea racemosa. These served to substantially correct the mal-conditions of the uterus, but did not, as I had hoped, have any observable effect upon the breast.

Circumstances rendered it impracticable to try the course pursued in the other cases, and as an experiment somewhat analogous, I had recourse to massage of the cervical and lumbar tracts of the spine and the surfaces of the ovarian regions. These were practised every other day, just previous to retiring at night. It seemed to produce a decided general invigoration, and at the end of two weeks the mammary enlargements were less tender to slight touch and they were slightly less in size, especially one of them. At the end of five weeks the reduction was most decided. In this case menstruation did not seem to interfere with the results of treatment. The massage was now continued at intervals of three instead of two days, and at the end of three months one lump was completely gone and the other more than two-thirds less; and here we came to a standstill, after a month of which I concluded to adopt massage of the neck of the womb itself. I did so every other day for ten days, and for a time it looked as though with positive injury to the patient, as her troubles were in every particular aggravated. I stopped all treatment, with the conviction that there was some element in the case other than existed in the instances just narrated, and was seriously considering whether surgical interference would not be wise.

Five or six days after stopping the treatment a sudden and rapid improvement commenced, and without any further medicine or treatment of any kind the patient was, before the end of one month, almost entirely well, with but a trace of the lump in the breast; and up to my latest intelligence, last summer, there was no increase and the general health was good.

Case VI.—Mlle. de C——. This case is more one of observation than treatment. The subject was petite, slight, very dark eyes, with remarkably heavy dark hair and eyebrows, and with just a faint growth on the upper lip. The lips were very full, complexion extreme brunette; the nature was altogether intense and off balance. She was at all times more or less hysterical, and was subject to attacks of light epilepsy—*petit mal*—and was insufferably wilful. Her chief amusement and occupation seemed to consist of falling in and out of love in the most tumultuous possible manner. One of her relatives, after considerable trouble, got her to come and see me concerning a growth in the right breast. She permitted and assisted in the investigation of her case, but refused point blank to receive treatment from me or anyone else. She said the swelling came whenever she had an affair of the heart, and went away between times; it had done so twice before. I examined the cervix and found that hard. The lump in the breast was very hard, but not so movable as in some of the other cases. There were no glandular swellings elsewhere. I did not see the case again for some months, when she came in with her sister to tell me that the love affair had burned itself up, and the tumor of the breast had also gone out—and so it had. An examination of the cervix was allowed, and the abnormal hardness had also disappeared from that.

Twice since this the conditions described have come and gone, each time under precisely the same circumstances. Should the girl ever marry, I have no idea whether it will serve as a benefit or the reverse—though I am inclined to believe the first.

Case VII., and the last I will tax your patience with, was that of an unmarried woman, somewhat famous in the theatrical world. For reasons that will readily occur to you all, I will avoid any close description, and only say that the patient was brunette, not sensual but sensuous, somewhat hysterical and highly emotional, and was in her thirties. She had for many years been under my professional care, but with only the common run of small maladies. About four years ago she came to me in an intense state of alarm at the discovery of a swelling in the left breast, the size of a small hen's egg, which became exceedingly sensitive to either light or heavy pressure. The ovaries were tender, the womb hard and painful upon touch, and the upper end of the spinal column was very sensitive. She had become engaged to be married, and had herself observed that whenever separated from her fiancé—with whom she was thrown much in company—she would feel better and the swelling slightly decrease.

I had her take two months entirely away from her intended, and submitted her to a uterine and ovarian massage. Before the expiration of that time she had become natural in every way, only that the swelling in the breast remained, though less than half its former size. I then advised marriage, which advice in the course of two or three months was followed. Within one month after marriage the tumor disappeared absolutely, and has never since returned. She has never been enceinte.

The cases which I have given, and a few others that I have seen, have impressed me with a certain degree of conviction that there is a class of mammary tumors, ugly and misleading in appearance, but which are nervous reflexes purely of trouble in the generative organs.

My observation thus far would incline me to associate them with a high degree of sexual differentiation, dominant emotion, strong disposition to hysteria, profusion of hair, eyebrows and eyelashes heavy and darker than the hair of the head, lips full, especially the upper one.

The tumors are characterized by hardness, freedom from attachment, great sensitiveness, especially upon light pressure; no other glandular enlargements; sensitiveness over the ovaries, the neck of the womb indurated and painful to touch, the upper cervical vertebræ tender, and a greater or less disturbance of menstruation.

Light pressure on the sensitive parts is likely to produce intense discomfort, whereas heavy pressure, though it may give pain, is apt to give also a sense of relief.

In quick action of intellect they are generally quite beyond the average, in their tendency to religious profession and observance of its rites they are apt to be tenacious, although their real religious performances have a tendency to fall somewhat short of the promise.

That my report may carry as nearly as possible its true value, I must add that I have had also a number of cases, in the main resembling those here cited, and with which similar treatment utterly failed to be followed by cure, and sometimes even by any relief. I have two cases at present under treatment, both of which give reasonable promise of recovery.

The seven instances given are not sufficient, of course, to establish the proposition embraced in the title of this paper, but I think they strongly favor its probability; at least I hope the recital has not been a waste of your time.

The Acting Assistant Surgeons, United States Army.—Dr. S. S. Turner, of Camp Sheridan, Mammoth Hot Springs, Wyo., writes: "Justice to Dr. Parker, Recorder of the Acting Assistant Surgeons' Association of the United States, induces me to ask your permission to state that I am informed by a medical officer now in the service, that acting assistant surgeons now entering the army are subjected to a rigid professional examination, covering practically the same ground as the examinations for commission. I was not aware of this change."

Clinical Department.

A CASE OF MILK-LIKE EFFUSION INTO THE PERITONEAL CAVITY.

By JAMES E. NEWCOMB, M.D.,

ASSISTANT PHYSICIAN AT ROOSEVELT HOSPITAL, NEW YORK, OUT-PATIENT DEPARTMENT.

I DESIRE to place on record a few facts concerning a case of the above nature. The general topic is one of great intrinsic importance and any new case is rendered doubly interesting at the present time in view of some recent and very able contributions to the literature of the subject. I refer especially to the paper read before the last Congress of American Physicians by Dr. S. C. Busey, of Washington, D. C., and to a more elaborate article by the same author published in the December number of the *American Journal of the Medical Sciences*.

In the latter, the case about to be narrated is briefly alluded to but not at all in detail, and I desire to express my thanks to Dr. Busey for his courtesy in placing me in possession of a very able *résumé* of the cases thus far known to medical history.

On September 11, 1889, J—— H——, a male child, two years of age, of Irish parents, first came under observation. Previously had never had any definite sickness whatever and had always been strong and vigorous. Five days before, his mother had noticed that he seemed to have some pain about the stomach, and on examination she found the abdomen considerably enlarged. The distention gradually increased. Two days later the penis and scrotum became œdematous and so remained. At the time of the first visit the circumference of the abdomen at the level of the navel was 23½ inches; two days later, 25¼ inches. There was no fever and no vomiting. The bowels were rather loose, and contained (the mother said) considerable "white curdy matter." Pulse 90–100 and regular; breathing somewhat labored from upward pressure of abdominal contents on the diaphragm, and ranging between 45 and 50 per minute.

The child was of fairly good flesh and strength but presented the square head, enlarged epiphyses, and other evidences of a rachitic tendency. The superficial abdominal veins were greatly distended and the cavity evidently full of fluid. The chest and contents seemed normal. The splenic and hepatic areas could not be made out. The urine was free from albumin, normal in reaction and color, and of 1.030 specific gravity.

The usual medical means entirely failed to remove any of the fluid. Puncture of the genitals relieved the local œdema slightly. On the 14th dyspnœa became so urgent that tapping seemed absolutely necessary. This was done (under antisepsis) with a small trocar and cannula, and all the fluid allowed to run out that would, compression being made meantime on the abdomen by successive turns of a roller bandage from above downward. The child experienced nothing but the greatest relief from this operation. The amount of fluid withdrawn was forty-four fluid ounces, of a milky-white color, alkaline in reaction, specific gravity of 1.016, solidifying on the application of heat and nitric acid. It did not on standing present any fatty layer at the top, as has been the fact in some similar previous cases, but the deposit at the bottom of a conical glass showed some small granular cells, about the size of the smaller red blood-cells and resembling the smaller cells of the lymph. No fat-globules were discernible under the microscope. There was considerable loose granular matter apart from the cell contents.

After the tapping the œdema disappeared from the genitals but the fluid gradually reaccumulated in the abdomen. A second tapping was necessary two weeks after the first. The amount was about, and the character precisely, the same as the first. After the second operation there was for a few days every probability that a third would be necessary, but the abdomen gradually subsided and in three weeks the child was apparently as well as ever, and has since so continued, as far as is known. The mother was told to bring him to me again on the first sign of any trouble. I have lost track of her, however, and do not know definitely about the case now. I omitted to state that after the removal of the fluid it was possible to map out the liver and spleen, which were apparently healthy.

Many interesting questions suggest themselves in connection with such a case. The writer has called the effusion "milk-like," not caring to commit himself to any definite theory as to its composition. Dr. Busey's admirable papers discuss all of these problems fully, and it would be impossible to go all over the ground here. It is interesting to note that only fifty-three such cases have been reported in the last one hundred and ninety years.

131 WEST SIXTY-FIRST STREET.

THE TREATMENT OF KELOID.

By GEORGE T. WELCH, M.D.,

PASSAIC, N. J.

KELOID is seldom, if ever, regarded as curable, most authors relegating it to the limbo of opprobrium medicinæ at once, though Dumreicker is said to have succeeded in removing one from the lip by the application of acetate of lead and alum in the form of an ointment. The disease has baffled surgery, always returning after excision, and presenting a more malignant appearance. This is all the more remarkable, as it is regarded as a hypertrophic growth of the fibrous tissue of the surface, and seated in the corium itself—a part easily accessible, and to be removed without difficulty.

But after the excision of a true keloid it would seem that the traumatic variety is developed in the cicatrix, a tendency to the disease being now hereditary in the surrounding cellular tissue. But even here I am inclined to believe that persistent applications of collodion and iodine might perform a cure, under proper methods, if persevered in for several months.

In the spring of 1888, J. B——, a thriving Swede, interested in oyster-planting in Raritan Bay, consulted me in reference to a keloid on the back of one of his hands, which he had recently injured while assisting a workman in dredging. I had seen the keloid before, when it was pinkish, shiny, and sending out its crab-like claws of fibrous tissue into the surrounding skin, but now it was angry in appearance, and very painful.

The patient was anxious to have it removed, but, being a sensible man, after hearing the result of the use of the knife, he agreed to continue, for an indefinite time, such remedies as I might prescribe.

After multiple linear scarification, as advised by Vidal, from which plentifully exuded big drops of black-looking blood, the surface was dried and then painted with collodion. The collodion was now continued for fourteen days, when it was allowed to scale off. The keloid was somewhat contracted and depressed, but a fantastic crop of coral granulations sprang up in all directions, and, as it were, in a night, some of them interlacing, and all attended with an intolerable itching. Scarification was again practised, but the collodion was enforced, with tincture of iodine:

℞. Tr. iodinii ..... ʒ ij.
Collodio ..... ʒ vi.
M.

This was applied freely, and the parts were painted over daily for a fortnight, when the continued cracking of this varnish would cause slight bleeding, and it was then permitted to scale off. Scarification would again be performed, the collodion and iodine reapplied, and the above process continued as before. Many times the cicatricial granulations would reappear, and sometimes the keloid

would spread out sideways in a new direction, but, upon the whole, an encouraging progress was at length manifested. The centre of the affected part became mobile, and of a natural color, and finally the margin was cured in spots, and the dimensions of the whole decreased from a diameter of three inches to a semilunar elevation next the fingers of two inches in length. The treatment, without variation, for this went on until, after about eighteen months from the beginning of the process, the disease had entirely disappeared, and the skin, slightly purplish in appearance, was flexible and healthy, and this without internal medication.

It is not probable one might soon find so docile and patient a man as this, but, given the conditions, I think better results might be anticipated in a persistent adherence to this line of treatment than by any other.

LIGATION OF THE LEFT SUBCLAVIAN IN THE THIRD PORTION FOR TRAUMATIC ANEURISM OF THE AXILLARY ARTERY.

By THOMAS D. PARKE, M.D.,

BIRMINGHAM, ALA.

James T——, colored, aged forty, laborer, was wounded by a pistol-ball, May 4, 1889, the ball entering the posterior and inner surface of the arm at the fold of the axilla, and causing immediate loss of motion in the arm. The location of the ball could not be ascertained. On Saturday, May 25th, three weeks after the accident, he noticed, so he claims, between dark and midnight, the formation of a tumor under the pectoralis muscles which caused pains, radiating over his breast, and difficulty in breathing. On the 27th I was called in consultation to see the case by Dr. Douglass, found a pulsating tumor, size of an ordinary egg, with distinct bruit on left axillary artery, and concurred in the diagnosis of aneurism. The consent of parties concerned could not be obtained immediately, but on the following morning the patient was transferred to Charity Hospital, and the operation of ligature of the third portion of the subclavian performed in the presence and with the assistance of several associates. The clavicle was raised, and it was after a tedious dissection through the infiltrated tissues that the artery was isolated and ligated with silk, in the absence of proper sized catgut. The patient was put to bed with the arm enveloped in cotton, and hot cans were placed in apposition. The arm was cold, but by the following morning was the warmer of the two.

The general temperature went during the night to 101° F. but fell to 99½° F. on the next day, above which point it did not subsequently rise. The pulse remained about 95 for three weeks after the operation. The dressing was changed on the sixth day, and pulsation, though extremely feeble, was felt in the radial on the third day after operation. Appetite was good and constant from the first, and there was practically no pain save some insignificant pain referred to the elbow of the affected side. This elbow pain had been a symptom from the beginning, so much so that the patient always contended that the ball was lodged there.

Sensation to touch was entirely absent in the arm prior to and for more than ten days after operation, and then returned gradually, never, however, to be complete. Sensation first returned to the under and inner side of the arm, then to the ulnar side of forearm and the little and half of the ring-finger, next to the radial side of the forearm, but very little sensation has ever returned to the thumb, index, and middle fingers.

During the first week of August he began to move very slightly his fingers, and by the 20th of same month could raise his arm a few inches from his side, due to action of deltoid.

Massage and faradization were employed interruptedly (due to apathy of patient) after the second week, but have had little perceptible effect.

After the aneurism had disappeared and the swelling of the shoulder and arm was reduced, the ball was located, in the neck, immediately in front of the anterior border of the trapezius muscles, rather deeply imbedded, and was removed, much to the mental relief of the patient.

SPORADIC CHYLURIA.

By L. WEHLAU, M.D.,

SCRANTON, PA.

On November 23, 1889, I was called to attend Mrs. R——, aged sixty-seven, a native of Germany, but having resided in this country more than thirty years. She was then suffering from croupous pneumonia of the left lower lobe, from which disease she is now recovering. On the ninth day of her disease her daughter called my attention to a singular condition of the urine, which in color resembled a mixture of coffee and milk with great excess of the latter. On standing for a while in a conical glass, three strata appeared. The upper one formed a creamy substance, the lower one showed white fibrinous coagula, the middle strata retained the appearance first described. Reaction neutral, specific gravity, 1.022. Under the microscope nothing but fat in molecular form and oil-drops could be seen. The next urine passed was normal, with large amount of urates. The woman, as far as known, had never before passed a similar urine. She had always been remarkably healthy. Simulation and deception can be positively excluded. Reading the article by Dr. James Tyson in Pepper's "System of Medicine," on Chyluria, I find that chyluria is a very rare disease in this country, and that this case differs from others in showing itself at such a late period of life for the first time. I regret to be unable to give an explanation of this occurrence. Filaria sanguinis could not be found.

CONCERNING ANTISEPSIS IN SUBCUTANEOUS INJECTIONS.

Dr. D. E. English, of Millburn, N. J., writes: "In reply to Dr. P. G. Udell, I would say that his plan of using the hypodermic method is entirely too 'fussy in detail' to be of practical use to the busy practitioner. Moreover, so much care seems to me unnecessary. I have used the hypodermic method freely for years, not hesitating to inject such medicines as tincture of digitalis, brandy, and quinine sulphate in solution, and have never yet caused an abscess; and I can only recall four slight indurations. I have given one patient over two hundred injections without causing more than two slight indurations.

"The morphine solution which I use is identical with that used in Roosevelt Hospital in 1883–84, viz.,

℞. Atropinæ sulph.,
Acidi salicylici, ... ā gr. ss.
Liq. Magendie, ... ℥ j.
M.

"But I think the manner of giving the injection is of prime importance. Draw into the syringe a few more minims than you wish to inject, then grasp the point of the needle with the thumb and finger of the left hand, with the right hand push a drop or two of the solution out of the syringe, and with these drops thoroughly wash the needle with the aid of the thumb and finger of the left hand. Make the injections, not hypodermic, but intra-muscular. After the injection, if possible, make the patient thoroughly exercise the muscle injected. Whether or not he can do this, massage the injected muscle until you are sure the solution is well diffused through the tissues. I have been using the same syringe for over seven years, and have kept it in the same Russia leather case, which I have no doubt is alive with all sorts of horrible microbes, but I think washing the needle with the solution keeps them out of the patient."

Progress of Medical Science.

A Method of Operation Intended to Diminish the Dangers of Resection of the Intestine.—The unfortunate results following the treatment of gangrenous intestine by means of primary resection of the intestine and the establishing of an artificial anus, impelled Dr. Hahn, of Berlin, to employ the following method: The gangrenous intestine is drawn out through the inguinal ring, a double ligature is applied, and the gangrenous portion resected between the two portions of the latter. Iodoform gauze is packed into the previously disinfected lumen of the bowel, which is then sutured. An incision is then made of from six to eight centimetres in length, in the linea alba, crossing the origin of the mesentery, so that the upper portion of the incision is above, and the other portion is below the point of crossing of the latter. For this purpose the incision is begun somewhat below the umbilicus, and ends closely above an imaginary line passing from one anterior superior spinous process to that of the opposite side. The abdominal cavity is opened to this extent, and both ends of the intestine drawn out of the abdominal wound at the linea alba. This is accomplished by means of a pair of dressing forceps, which grasp the ends of the bowel by means of the double ligature threads before mentioned. The wound in the hernial region is irrigated and tamponed with iodoform gauze. Thereupon the exact condition of the intestine is determined, and, if no further resection is necessary, the sutures are applied in the usual manner (circular suture). Strips of iodoform gauze are placed under the line of sutures, so that the bowel, so to speak, rides upon the same; or from both sides of the bowel strips of the same material are led to the mesentery. The latter method is preferred, inasmuch as they are more easily removed. Then the bowel and gauze are lowered into the abdominal cavity, and the ends of the strips led out through the abdominal wound, and are fastened in the latter, whereby the bowel is secured to the neighborhood of the abdominal wound. Between the strips the abdominal wound is still further packed with iodoform gauze, and the skin of the abdomen united over all by means of about three superficial sutures.—*Annals of Surgery.*

The Effect of Distention of the Abdomen on Circulation and Respiration.—The effects of pregnancy, ovarian dropsy, ascites, and other diseases leading to great distention of the abdomen, in impeding respiration and disturbing the action of the heart, though there is little unanimity or precision in the opinions that are entertained respecting them, are generally admitted. Such affections are, indeed, of a chronic nature; the abdominal walls have time to yield, and the organs, both in the abdomen and in the chest are enabled to accommodate themselves to the altered conditions. Experiments have been recently undertaken to determine the effects of sudden distention of the abdomen in animals, by Dr. G. Heinricius. It is generally believed that in pregnancy there is marked increase in the tension of the systemic vessels, and that, as a consequence, the heart undergoes hypertrophy. But although such statements are to be found in almost every gynecological text-book, the evidence on which they rest is extremely slender. In order to determine whether any obstruction to the circulation which may exist in the uterine vessels in pregnancy would raise the general blood-pressure, Dr. Heinricius first performed the very simple experiment of tying the aorta, just above its division into the iliacs, and found that in four rabbits no change took place in the arterial tension of the carotids. Hence no effect was to be expected from ligature of the uterine arteries, nor from any such obstruction as might proceed from their distribution in the pregnant uterus and in the placenta. He next proceeded to ascertain by experiment the effects of distention of the abdominal cavity in the rabbit and cat. He employed a double cannula, which was introduced through or at the side of the linea alba by a small puncture in narcotized animals; one arm of the cannula was connected with a vessel containing normal saline solution at the temperature of the blood, and the other with a manometer. Arrangements were further made to record graphically the respiration and the blood-pressure in the carotid. The respiratory and blood-pressure curves were taken after each 50 or 100 c.c. of the solution had been injected into the abdomen from the vessel, and the phenomena which were presented proved to be remarkably uniform. In all the experiments, which numbered fifteen, it was found that the abdominal cavity could be filled with a large quantity of fluid, so that the parietes were quite tight, without either pulse or respiration being materially disturbed. It was only after very great distention had been produced that the respirations became more frequent and deeper, the expiratory effort being particularly well marked. This dyspnœa was apparently attributable to the diaphragm being pressed upward, and the capacity of the thorax correspondingly diminished, so that mechanical obstruction to respiration was occasioned. The effect of this was that the accessory respiratory muscles were brought more into play, and the breathing became more and more thoracic in character. But these efforts soon became insufficient to compensate for the defective action of the diaphragm. The respiratory centre became excited, but was soon paralyzed by the venous blood. The respirations underwent a change; they became first shallow and slow, then deeper, dyspnœa finally occurred, and the animal died. If we turn now to the effects of the distention on the circulation, we find that when the distention became considerable the pulse at first increased in frequency, then became fuller, afterward less frequent, and before the death of the animal usually suddenly smaller. The arterial blood-pressure first began to rise when the frequency of the pulse had considerably diminished, and then gradually fell as the pulse became smaller. Dr. Heinricius says that the abdomen may undergo great distention without abrogation of the more important vital functions. The abdominal cavity of a rabbit can support in this way the introduction of 500 c.c. of fluid without difficulty, and nearly a litre and a half of fluid can be further injected before dangerous symptoms supervene, clearly showing how extraordinarily yielding the abdominal parietes are, and affording a proof that it is not necessary to appeal to the slowness with which they are distended in pregnancy, and in cases of abdominal tumor, to explain the slight interference with the main functions of life that occurs in those conditions.—*Lancet.*

The Histogenesis of Abscess of Cellular Tissue from Invasion by Staphylococci.—Dr. Hohnfeldt, of the Pathological Institute of Königsberg, has devoted much study to this subject. His experiments of injecting staphylococci, and thereby producing suppuration, confirmed the teaching of Cohnheim, that pus-corpuscles were in every instance wandering leucocytes exclusively which had penetrated the walls of the blood-vessels, altered in character by the inflammatory irritation, and that they therefore did not derive their origin from growth of the fixed cellular tissue-cells, nor by division of the leucocytes. If the experiments of other distinguished workers had led them to a contrary opinion it was probably due to the fact that the substance introduced subcutaneously, oil of turpentine, had set up a necrotic process instead of a simple inflammatory one. As regarded the relation of the development of cocci to the leucocytes, his experiments had not in the least supported the assumption that when free passage of cocci took place into cells the former were destroyed. The indications were, on the contrary, that the pus-cells formed a favorable soil for the growth of the cocci, and that the latter gradually destroyed the former. He could not, therefore, confirm Metschnikoff's theory of phagocytes.—*The Medical Press.*

A Sensitive and Convenient Test for Albumin, says Dr. Mortimer Granville, is trichloracetic acid. This precipitates albumin and not peptones.

MEDICAL RECORD:

New York, February 15, 1890.

THE TESTICLE IN ANCIENT PHARMACY.

DR. ARCHIE STOCKWELL writes an elaborate historical and critical article in the *Therapeutic Gazette* regarding the subject of testicular secretion in therapeutics. It is not surprising that in olden times, when every conceivable agent, from tongue of snake to eye of bat, was put into pharmacy, that the sexual organs should also be utilized. As a matter of fact, Dr. Stockwell has succeeded in finding a great number of references to the use of the testicles of various animals in the cure of disease. We cannot repose the fullest confidence in Dr. Stockwell's historical accuracy or soundness of judgment, for he informs us that "we now know" that Socrates was sentenced to death for his sexual crimes, and that the faults of Paracelsus were venial, and consisted, "like those of Pasteur," chiefly of "theatrical enunciation and denunciation, and the drawing of conclusions from imperfect data." If ever there was a liar and quack, it was Paracelsus. However, he anticipated Brown-Séquard, for we are told that out of *sperma hominis* he made his homunculus, and asserted that "it was good against the imbecility of the instruments of generation." In the *Hortulis Genialis* of Baricellus, Genoa, 1620, is found a receipt for sexual rejuvenescence, the principal ingredient of which is the testicle of the wild boar; and a parallel prescription is offered in a work by Elzear Blaze, one hundred and twenty years later.

During the seventeenth century reproductive products, as obtained from mammals, birds, and fishes, still enjoyed an enviable reputation as cerebro-spinal and genital excitants; they were especially endowed with specific attributes in diseases of mucous membranes, or those due to nervous derangements, such as "the falling sickness," chorea, and neurasthenias. They were, however, more generally employed to restore sexual vigor and increase virility, and found a prominent place in the London Pharmacopœia as issued by the Fellows of the Royal College of Physicians in 1676, and also in Salmon's "New London Dispensatory" of 1684.

In the eighteenth century most animal remedies were dropped from the Pharmacopœia, and the testicles among them. It is very evident that they were recommended and used in ancient times on purely fanciful grounds, and that, as administered, they could have had no more physiological effect than so much dried albumin. The leucomaine or ptomaine, thought to be in the fresh juice, and asserted to be represented by a substance called "spermine," must be destroyed by drying, heating, and addition of various chemical agents. The administration of testicles in diseases has in the past been only a kind of offshoot of phallic worship, and the modern use of testicular secretion seems to be of much the same character.

STRANGE, IF TRUE.

IF it were possible to credit all the tales that are told of the wonderful curative powers of hypnotism, we might well believe that the medical millennium was nigh, and that the triumph of mind over matter was nearly complete. There is scarcely an ill, whether functional or organic, which has not been approached, and, if we could only believe it, cured, by this young but much-ridden therapeutic hobby.

One of the most remarkable stories of hypnotism that we have yet seen is related by Dr. Herrero in a work which he has recently published, and which we find quoted in the *Revista Médica de Sevilla* of November 30, 1889. The patient was a congenital deaf-mute, seventeen years of age, of good bodily and mental health. She was made to understand by signs the object of the treatment, and joyfully consented to submit to the experiment. Daily séances were held for a month with no apparent result, and both physician and parents were discouraged; but the patient seemed still to have faith, and so the treatment was persevered in for about two weeks longer. At the end of that time the mother reported, with tears of gladness, that the girl could hear a little, and it was found that the watch could be heard against the right ear. Daily hypnotizations were then continued for the space of six months, at the end of which time the hearing in the right ear was found to be normal and that in the left ear very good. The hearing being restored, it only remained for the patient to learn to talk, and this she did in the natural way, aided by hypnotism.

We tell this story as it was told. If any of our readers want to try the experiment for themselves, they can find plenty of material to work upon.

INDECENT ADVERTISEMENTS.

A LAW against indecent advertisements has just been passed by the British Parliament. It prescribes fine or imprisonment on any person who affixes to, or inscribes on, any house, building, etc., visible from any public highway or footpath, or delivers or attempts to deliver, or exhibits to any person being in or passing along any street, public highway, or footpath, or throws down the area of any house, or exhibits to public view in the window of any house or shop, any picture, or printed or written matter, which is of an indecent or obscene nature.

It is also expressly declared that any advertisement relating to syphilis, gonorrhœa, nervous debility, or other complaint or infirmity arising from or relating to sexual intercourse, shall be deemed to be printed or written matter of an indecent nature within the meaning of the act.

A law something of the above character would materially cripple the income of some of our daily papers; but it would be a most salutary thing.

In this city most of these papers contain the most open

advertisements of abortionists, of persons desiring "housekeepers," of cures for syphilis, impotence, and sexual debility; while the telegraph poles of the east and west side are plastered with advertisements of specifics for gonorrhœa, and the shop-windows are full of pictures of denuded women illustrating the virtues of various brands of cigarettes.

The daily press is very indignant over the activity—sometimes over-energetic—of Anthony Comstock. But if indecent advertisements were not so profitable, perhaps Mr. Comstock would receive more commendation for his work.

In illustration of the power of the advertiser to modify journalistic opinions we quote from the Portland (Ore.) *Journal*. It seems that Oregon has a medical practice act, and one of its first results was to drive from the city a certain advertising specialist. Says the *Journal*:

"Upon what hypothesis the board rejected his diplomas we can't divine. Dr. A—— is one of the oldest specialists on the American continent, and seventeen years ago he practised in this city for a period of four years. He has practised in San Francisco, Philadelphia, Chicago, and many other cities of like importance, and is recognized as one of the greatest eye and ear physicians of this age. This unfortunate circumstance will certainly be an unwelcome piece of news to the press of this coast, as the doctor is one of the heaviest, and most extensive advertising physicians in America, and had he located in Portland, as he expected to do, he would have advertised in every paper on the coast, and probably spent $50,000 the first year with newspapers."

THE MEDICAL PORTION OF THE PENSION BUREAU.

We have noted at various times criticisms as to the organization and work of the medical portion of the United States Pension Bureau. Dr. Henry Bixby Hemenway has published an article upon this subject in the *Medical News* of February 1st, and has embodied in it the drafts of two bills now before Congress.

Dr. Hemenway asserts that the medical examiners of the Pension Bureau are insufficiently paid, and that the medical officers at Washington are insufficient in number, and, perhaps, deficient in quality. Pension surgeons, according to the present law, are paid $2 for each examination up to five; after that $1 for each examination.

In the Washington office the force consists of one medical referee, one assistant, two surgeons, and eighteen medical examiners. These men receive each, per annum, respectively, $3,000, $2,500, $2,000, and $1,800.

Life insurance companies pay their medical examiners about $10,000 per annum.

The first of the bills prepared by Dr. Hemenway adds one surgeon and six examiners to the present force at Washington, and increases their salaries as follows:

Medical referee, from $3,000 to $4,000; assistant referee, from $2,500 to $3,600; surgeons, from $2,000 to $3,000; medical examiners, from $1,800 to $2,500.

The second bill provides that each member of each board of surgeons for the examining of applicants for pensions shall, as now authorized by law, receive the sum of $2 for the examination of each applicant.

While we believe that these bills are eminently just and ought to become laws, it is not here that the work of improvement in the medical service of the Pension Bureau should cease. There is need of a better organization of this service, and a removal of it from politics. As it is now, the offices, we are told, are party spoils; and if the salaries are increased the spoils will be greater, while the medical work will not necessarily be in the slightest improved. Already very severe criticisms have been made on the character of these political pension boards.

LEGISLATING MEDICAL WOMEN INTO INSANE ASYLUMS.

We observe that a plan is on foot to secure the enactment of a law compelling the appointment of medical women for attendance upon the female insane in our State asylums. The editor of *Harper's Weekly* has lent his potent pen for the promotion of this project.

We should regard such a law as most unwise, unjust, and unnecessary.

We quite believe that medical women can be of especial service sometimes in lunatic asylums; but the medical superintendent ought to be allowed to exercise his judgment in this matter, and there should be no special class of doctors legislated upon him.

The idea that medical women can, as a rule, make examinations and carry out gynecological treatment on the insane better than men is, we believe, not supported by experience. As a matter of fact, also, it is not very often that local treatment is indicated in insane women. Finally, the argument that an insane person who desires a woman physician should be allowed the privilege is too extraordinary to deserve comment. The ordinary experience of humanity is that maniacs, dements, paretics, etc., do not possess capacity for wisely chosing what is best for themselves. Our Legislature might as legitimately try to provide a piece of the new moon in case the female lunatics desired it.

Physicians should be chosen only on a basis of medical skill, character, and training, not on a basis of sex or the preferences of lunatics.

EXAMINATION OF CANDIDATES FOR ARMY MEDICAL SERVICE.

We call attention to the following notice from Surgeon-General Moore, of the meeting of an Army Medical Board in this city for the examination of candidates for the medical service, and trust that it will receive due consideration from all concerned:

"An Army Medical Board will be in session in New York City, N. Y., from May 1 to 31, 1890, for the examination of candidates for appointment in the Medical Corps of the United States Army, to fill existing vacancies.

"Persons desiring to present themselves for examination by the Board will make application for the necessary invitation to the Secretary of War, before April 1, 1890, stating the place of birth, place and State of permanent residence, and inclosing certificates based on personal knowledge from at least two physicians of repute, as to professional standing, American citizenship, character, and moral habits; also, statement of service in hospital from

the authorities thereof is desirable. The candidate must be between twenty-one and twenty-eight years of age, and a graduate from a *Regular Medical College*, as evidence of which his diploma must be submitted to the Board.

"Further information regarding the examinations and their nature may be obtained by addressing the Surgeon-General, United States Army, Washington, D. C.

"JOHN MOORE, *Surgeon-General, U. S. A.*"

News of the Week.

Give us a Rest.—Now that the epidemic of influenza is over we trust that the poor tired doctors will have a rest. It is really too bad to learn that "our doctor made one hundred and forty visits yesterday," also, "our doctor is very busy, and has not slept for fourteen nights." Too busy by far. How do our patients find out all this? But seriously, if the grip had lasted much longer it might have killed off all our best men. We hope this good man who owes himself fourteen nights sleep will soon catch up; that the poor man who "has not had his clothes off for a week" has had a bath, and that the one hundred and forty daily patients of the other unfortunate overworked man are still alive to appreciate his herculean labors. Take care doctor! Either a pillar of salt or an obituary are in waiting.

Mr., not Doctor.—To the name of Mr. Henry Mortimer Archer an M.D. was affixed by our own misapprehension. Mr. Archer, who is an undergraduate, desires to free himself from an attempt to sail under false colors, and asks for a correction, which we cheerfully make.

Body-snatching.—A case of body-snatching has come to light in Knoxville, Tenn. The "subject" was found in the Tennessee Medical College.

National Convention on Medical Education.—The faculties of several of the medical schools of Baltimore, Md., and the staff of the Johns Hopkins Hospital have been considering the subject of reforms in medical education. It was the unanimous sentiment that the matter should take a national rather than a local form, and in accordance with this view a proposition was made that the medical schools of the United States be asked to send representatives to a conference to be held at Nashville during the approaching meeting of the American Medical Association in May. To give greater weight to this movement a meeting was held yesterday to take further action. After the subject had been thoroughly discussed a circular was drawn up, to be sent to the medical schools of the United States, stating that it is not expedient nor practicable for the medical schools of any State to assume alone the responsibility of adopting advanced methods. Yet, fully convinced of the pressing need of a change, and earnestly desiring to see it consummated, they are unwilling to let matters rest longer without an effort on their part to improve them. Fully aware of previous ineffectual efforts in this direction, they realize that times have changed, and they believe that a repetition of them at this time would have a good prospect of success. The meeting of the American Medical Association in May will offer a good opportunity for a general discussion of the subject, and the medical colleges are requested to send delegates to a conference at that time "for the full consideration of medical education in this country and measures for its improvement." The following subjects are considered as most likely to come up for consideration: First, three years' course of six months sessions; second, graded curriculum; third, written and oral examinations; fourth, preliminary examinations in English; fifth, laboratory instruction in chemistry, histology, and pathology.

Medical Exhibits at American Medical Association.—The forty-first annual meeting of the American Medical Association will be held in Nashville, commencing Tuesday, May 20th, and continuing till Friday, May 23d. In connection with the meeting of the Association, which promises to be a very interesting one, there will be held the usual exposition of pharmaceutic, surgical, and sanitary products and appliances. This exposition is expected to be one of the largest and most complete exhibits of the kind ever held. The Committee on Exhibits has secured for this display the Amusement Hall, on Broad Street, which is both commodious and accessible. The Tennessee Druggists' Association will meet in Nashville at the same time, affording an additional inducement to exhibitors. Pharmacists and others intending to exhibit their manufactures should address Dr. J. Berrien Lindsley, Chairman of the sub-Committee on Exhibits. To defray expenses each will be required to pay an entrance fee of $10, which will entitle him to twenty-five square feet of space, each additional square foot costing 50 cents.

A Night Medical Service.—It is proposed to establish a night medical service in London. Our own night medical service has, so far as we can learn, lapsed into innocuous desuetude.

The Hospital Collection Fund at last accounts had reached the sum of $53,670.22.

The State Board of Health.—Governor Hill recommends an act abolishing the State Board of Charities and the State Board of Health, and vesting their respective powers in single officers, thereby concentrating responsibility.

Trying to Save the Adirondacks.—Several prominent physicians of this city have joined in an appeal to the people of the State for the preservation of the Adirondack forests. These are gradually being destroyed through the introduction of small railroads in the interests of the lumber and iron industries.

Dr. Benedict Schulz, of Vienna, died on January 5th, at the age of seventy. He was the first Austrian physician to place electrotherapy upon a scientific basis. His first communication upon this subject was made in 1843.

Professor C. Westphal, of Berlin, one of the most eminent of German alienists, died recently, after a long illness.

The Fate of the Doctor who Trusted to a Telephone.—The *North American Practitioner* tells of a doctor in a neighboring State who was called one rainy night to attend a case of croup. Not wishing to get wet, he directed the child to be held to the telephone (so the story goes), and, hearing it cough, corroborated the diagnosis and gave directions for treatment. He then returned to bed, and on calling the next morning found the child doing well—under the care of another physician.

A New Medical College.—The Legislature of California has passed a bill appropriating $80,000 for the erection of a new medical college for the University in San Francisco. It will be built opposite the City and County Hospital.

A Bacteriological Institute of Preventive Medicine is to be established at the University of Cambridge. One of the principal lines of work will be anti-rabic inoculations.

Dr. W. D. Greene has been appointed health physician to Buffalo, N. Y.

Dr. Fraser C. Fuller has been appointed surgeon to Charity Hospital, N. Y.

Merry Students among Corpses.—A Philadelphia paper has a long article, with the above heading, detailing a visit to the dissecting-room in which ruffianly students were described as sporting with the remains of poor humanity. If there is any truth in the account every medical man should cry shame.

To Take the Place of Hard Cider.—A peculiar result of the drinking of ice-cold water from a spring in Stonington, Conn., is reported. The water flows from a crack in a high rock, and the veins of a man who drinks from it begin to swell, and he looks and feels as though he were about to burst for the next ten minutes. The swelling gradually subsides and no serious effect is felt, except a slight buzzing in the ears. It is the talk of the neighborhood, and everybody is eager to try the effect of the water. A specimen has been sent to Boston for analysis.

New Hospitals.—A German hospital is to be erected in Brooklyn, and also one in Jamaica, Long Island. The managers of each have already elected themselves.

The Philadelphia Lying-In Hospital has been closed on account of an epidemic of puerperal fever.

Pambotani. — Dr. F. Semeleder, of Mexico, writes: "The name of the Mexican fever remedy mentioned on page 84, No. 3, Vol. 37, is 'Pambotani.' A few years ago much fuss was made about it, now it is completely forgotten and nobody thinks of it any more. Botanical name unknown."

A Physician Robbed.—Dr. William M. Hutchins, of 304 Henry Street, Brooklyn, was eating his supper one evening about 7 o'clock, when the servant, who had answered a ring of the door-bell, informed him that there was a lady in his office. The doctor finished the meal hastily, but when he entered his office there was no one there. A glance showed him that his overcoat and a black diagonal frock-coat had been taken. They were valued at $40 each.

Retained as Medical Expert in Leprosy.—The British Government has decided to retain the services of Dr. A. C. Smith, of Newcastle, N. B., as permanent medical expert in leprosy. Since the discovery of three cases of leprosy on Cape Breton Island last year, Dr. Smith has been making a thorough investigation into the ramifications of the disease, and although there is no cause for alarm, it has been deemed expedient to continue the investigation. Dr. Smith has for some years acted as "visiting physician and medical adviser" at the hospital for lepers at Tracadie, N. B.

Prize by College of Physicians of Philadelphia.—The College of Physicians of Philadelphia will award the Alvarenga Prize, consisting of one year's income of the bequest, to the author of the best memorial or unpublished work on any branch of medicine, the College reserving to itself the right to reject all essays not considered worthy of the prize, and that they will be received by the secretary, Isaac Norris, Jr., until June 1, 1890.

Protection of Croton River.—The annual report of the State Board of Health shows that one hundred and forty-two violations of the rules for the protection of the Croton River and its tributaries have been reported by the Commissioner of Public Works for New York City. Lists of all violations have been transmitted to the Boards of Health of the various villages and towns in which the premises are located, with instructions to carry out the rules. Many of the violations reported are rather cases of neglect than of wilful refusal to conform to the rules. In some cases the alterations of existing conditions to conform to the rules will be a matter of some expense, and the parties affected are reluctant to incur this without a prospect of reimbursement from the city of New York. A hardship would be worked in some cases if this were insisted upon; but there is almost no instance in which compliance with the rules will not benefit residents upon the watershed as well as the city, and the manifestation of a proper spirit will doubtless bring about an equitable division of the outlay.

Our Medical Pension Boards receive the following comment from the editor of the *Kansas City Medical Index*: "How different is the medical staff of the United States Army from the United States Pension Boards! Contrast the average army surgeon, for example, with the Kansas City Board of Pension Examiners; fie! Compare a glow-worm with the aurora borealis, the hill of the piz-ant with the mighty Andes, a bacterium to the universe!" Perhaps our esteemed contemporary is a little severe. It is true that there is too much politics in Pension Boards, but we can hardly expect the members should have the qualifications exacted of army officers.

The Number of Deaths from all causes in the State of New York during the year 1889, according to a summary of the figures given by the *Monthly Bulletin*, was 104,233. At an estimated population of the State of 5,750,000, the death-rate was 18.65 per 1,000. But reports of 3,000 deaths were received too late for insertion, making the whole number of deaths 107,233. About 80,000 of the population make no return of vital statistics, and these are disregarded in the estimate of population. The mortality rate for the cities was 22.06, that for the country 13, per 1,000. The statistics for five years for typhoid fever, diarrhœal diseases, diphtheria, and consumption, show some variations, but no considerable increase in percentage of any of them. The percentage of deaths from consumption in 1889 was slightly higher than in 1888, but lower than in either 1885, 1886, or 1887. The greatest number of deaths in a single month was 10,806 in July. The next greatest number was in March, 9,547, and the smallest number was in November, 7,285.

The College Yell of the Homœopathic students of this city is spelled as follows: "Rah! Rah! Sim. Foom, Ah! Similia—Similibus! Cu-ran-tur!"

Dangerous Hypnotics.—Liebreich asserts that the new hypnotic somnal is neither safe nor efficacious. Dr. Marandon de Monthyel has published observations unfavorable to sulphonal, asserting that it is uncertain and may have dangerous cumulative effects. His views are supported by Professor Mairet, and by Drs. Jastrowitz and Knoblauch. Nevertheless, few serious results have in reality been observed.

Barmenite is the name given to a new compound consisting chiefly of chloroborate of sodium, and used for preserving food. The German government, says *The Therapeutic Gazette*, is taking particular interest in barmenite. Recently, for the sake of a trial, a whole battalion of the Sixty-fifth Regiment, in Cologne, was fed with meat which eight days previously had been treated with barmenite. The meat was found to be excellent both in taste and appearance.

Peculiar Suits Against Doctors.—A woman has brought suit against a Philadelphia physician because he positively pronounced her to be pregnant, although time proved the erroneousness of the diagnosis. She brings a suit on the plea of "bringing disappointment." A widow in New York has, it is said, brought a suit for damages against a well-known neurologist for taking her husband's brain, and also for violating an alleged contract to give her $1,000 for using her husband as a medical object-lesson. The brain was that of the original case of athetosis.

The Hospital Collection.—The Saturday and Sunday Hospital Collection Fund had, up to January 29th, reached the sum of $52,618.61.

A Foot Reflex.—Two cases are reported by Dr. Robert Abbe, and one by Dr. V. P. Gibney (*Annals of Surgery*), showing that sometimes a painful flat foot may be entirely relieved by treating and removing an ingrowing toe-nail.

A Medical College for Colored Students has recently been organized at New Orleans, in connection with the New Orleans University.

The Medical Profession of Hot Springs.—The *Weekly Medical Review* says: "We have received a list of sixty-one names of men employed by thirteen Hot Springs "doctors," under license from the city clerk, to drum or solicit on trains, etc., for them. The correctness of the list is undoubted, as it is subscribed and sworn to. And yet we recently heard the declaration that this sort of thing had been done away with at Hot Springs."

A Paraplegic Surgeon.—Professor Nussbaum, of Munich, writes a correspondent of the *Medical News*, operates every morning at eight, and appears punctually on the hour, wheeled into the arena by a special porter of the hospital. He operates sitting before a low table, for he is not able to stand. I saw his clinic of November 28th, in which he operated on three cases. On November 27th, he performed three operations; on the 26th, a supra-pubic lithotomy; on the 25th, an amputation of the breast for carcinoma with involvement of the axillary glands; on the 24th another supra-pubic lithotomy. Up to that time, since November 3d, he had performed six such operations. This shows what a great amount of work he takes upon himself to perform. He lives in the hospital, and now spends most of his time there, and is the only man of note who operates through the summer.

Professor Leyden, of Berlin, has been called to St. Petersburg to attend the Czar.

Dr. William Goodell, of Philadelphia, has been invited, by the Gynecological Section of the Tenth International Medical Congress, to open the discussion on the Induction of Premature Labor.

The Inoculation of a Criminal with Leprosy.—The *Transactions* of the First Dermatological Congress, held at Prague on June 10 and 12, 1889, contain a paper by Dr. Arning, who inoculated the condemned criminal with leprous tissue at Honolulu (*British Medical Journal*). Dr. Arning, in his paper, gives a detailed account of the circumstances connected with the inoculation, of the local manifestations which followed it, and of the subsequent condition of the man as reported to him from the Sandwich Islands. He summarizes the whole case as follows: An apparently healthy, strikingly vigorous man, without any hereditary taint of leprosy, was in the end of September, 1884, inoculated with lepra material, which was taken directly from a child who was the subject of grave tubercular leprosy, and who had passed through an attack of leprous fever. The chief inoculation consisted in the insertion of a small piece of a tubercle in the left forearm. Four weeks afterward there occurred rheumatic pains, first in the left shoulder, then in the other joints of the left arm, and later a painful swelling of the ulnar and median nerves, all these symptoms occurring without fever, and with very little constitutional disturbance. During the next six months the neuritis gradually abated, and there formed a small leprous nodule in the keloid-looking inoculation scar. In the edges of this keloid scar, sixteen months after the inoculation, lepra bacilli could be found. Then comes a gap in the continuous observation of the patient, on account of Dr. Arning's departure from Honolulu, but it is known that in December, 1887, there were unmistakable symptoms of leprosy in the man. After another year, in September, 1888, the patient was the subject of fully developed leprosy.

Goethe and the Influenza.—Lewes, in his "Life of Goethe," says of the poet's last illness that he had taken cold, and the physician on arriving "found him very feverish with what is known in Weimar as the 'nervous fever,' which acts almost like a pestilence." It is inferred from this that the great German died from the influenza.

Antiseptics in the Barber-shop. — The fears of microbes, which is rapidly becoming a dominant factor in modern life, has lately received a curious illustration at Nordhausen, a small town in Prussian Saxony. A municipal edict has been issued that all barbers, hairdressers, and "tonsorial artists" generally, shall, under legal penalties, well and truly disinfect their instruments every time after they have been used.

The New York Medical Union Banquet was held at Sherry's, corner Fifth Avenue and Thirty-seventh Street, on the 11th inst. Dr. H. S. Oppenheimer, the newly-elected President, proved a happy toastmaster, and introduced the following speakers: Dr. John Shrady, William A. Purrington, Esq., Drs. N. S. Roberts, W. E. Forrest, H. J. Boldt, Ralph Waldo, D. E. McSweeny, J. B. McMahon, and Dr. A. S. Hunter. The affair, which was much enjoyed by the members and their ladies, ended with a dance.

Society Reports.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, Tuesday, January 7, 1890.

THE PRESIDENT, DR. GEORGE W. JACOBY, IN THE CHAIR.

Neurotic Tumors of the Breast.—A paper by DR. E. P. FOWLER, entitled "Neurotic Tumors of the Breast" (see p. 179) was read, in the absence of the author, by Dr. Ingram.

Seven clinical cases were adduced, giving their history, the treatment, and results.

Dr. Fowler inclined to believe that the cases cited gave reasonable ground for regarding these and similar ones as being dependent upon certain conditions of the generative apparatus, conjoined, possibly, with the spinal cord, depending sometimes, perhaps, on local hyperæsthesia and sometimes on local or general anæmia.

These cases seemed to accompany a more than ordinary sexual differentiation, a disposition to hysteria, profusion of hair, eyelashes and eyebrows darker than hair, lips full. The tumors were characterized by hardness, freedom from attachments, great sensitiveness upon light pressure (heavy pressure, though painful, might at the same time afford a certain degree of relief), no other glandular swellings, and great sensitiveness over the ovaries. There was also an indurated and sensitive cervix uteri, and often extreme sensitiveness along the cervical vertebræ.

The doctor found the subject of these troubles decidedly above the average in intellectual ability and quickness; apt to possess a strong religious bias, though not necessarily a firm moral groundwork. The treatment consisted in great degree of massage applied to the neck of the womb, the ovarian regions, and the cervical portion of the spinal column, and marriage alone might often furnish every requisite.

The tumors observed by Dr. Fowler have varied between the size of an English walnut and that exceeding the volume of a hen's egg.

The Proposed New Lunacy Bill.—DR. FREDERICK PETERSON presented for the consideration of the Society the proposed new lunacy law for New York State, which had been drafted by Dr. Stephen Smith, and which had last year passed both houses under the title of the "Gallup Lunacy Bill." It had failed to become a law through the Governor's indisposition to affix his signature. The bill would be re-introduced at this year's legislative session, and Dr. Smith was desirous of having the Society's criticism of its provisions previous to such introduction. It would be remembered that the bill was informally discussed at a meeting of the Society last Spring, when the manner of commitment proposed in it had been strongly condemned because of its complexity. Although somewhat revised in portions, there had been no particular change made in the paragraphs relating to commitment, which read as follows:

Examiners in Lunacy.—"Whenever a justice of the peace or a superintendent of the poor of a county, or the overseer of the poor of a town, or a judge of a court of record shall receive information that a certain person, deemed insane, should be placed in custody, for either of the causes stated in section first of this act (in accordance with Form B), the said justice, or superintendent, or overseer of the poor, or judge shall, by an order in writing (in accordance with Form C), direct two examiners in lunacy to examine the alleged insane person and report to him under oath within one day, exclusive of Sunday, after their respective examinations (in accordance with Form D), the results of such examination, with their recommendation as to the special action necessary to be taken in the case; if a justice of the peace, or a superintendent or overseer of the poor issues the order for an examination, he must personally visit the alleged insane person; if the physicians certify that the person so examined is not insane, the justice or superintendent or overseer shall dismiss the case, but if they certify that he is insane, and a proper subject for commitment, as provided in section one of this act, said justice or superintendent or overseer shall certify, under his hand, to the correctness of the proceedings and to his personal visit (in accordance with Form E), and shall cause said certificates to be delivered to a judge of a court of record within two days, exclusive of Sunday, of the date of the last certficate made, which last certificate must not bear date of more than two days of the first certificate.

Manner of Commitment.—"On receiving said certificates from a justice of the peace, or superintendent or overseer of the poor, or on receiving the sworn certificates of two examiners in lunacy, appointed by himself, certifying to the insanity of any person, and recommending that he be placed in custody for cause, then and in either case the said judge may or may not visit the alleged insane person, or require that he be brought into court, but he shall state in the order of commitment whether or not he saw him, and if he did not see him he shall give the reason therefor; the judge may or may not take further testimony, and he may call a jury, but in either case, if satisfied that the person is insane, and that the reasons given for his commitment in the certificates are just and right, he shall make an order (in accordance with Form F), committing said person to the custody of the superintendent of the proper State asylum for the insane, or the keeper or superintendent of a private asylum or licensed house for the insane; said order shall be issued within five days after the date of the last medical certificate; a copy of said medical certificates and answers obtained in accordance with Form D, shall be transmitted with the order of committment to the superintendent of the respective asylum and the original thereof shall be filed in the office of the clerk of the county, and shall be inaccessible except on the written order of a judge of a court of record; nothing in this section shall be construed to prevent the commitment of an insane person in accordance with the provisions of this act to the asylum of any county authorized by law to have the care of the acute and chronic insane, *provided* the said insane person is a legal resident of said county.

Lunatic Informed of the Action.—"It shall be the duty of the judge, before he makes the order of commitment, to cause the alleged insane person to be fully informed of the action about to be taken concerning him; and if said insane person, or his friends or relatives, demand that other testimony be taken, or that a jury be called, the judge shall act at his discretion, but if he deny the motion, he shall state the reasons therefor in the commitment."

There were many admirable reformatory features in the bill, of which physicians with asylum experience were cognizant. These related to the removal of patients to institutions by attendants of their own sex; the provision for the reception and discharge of voluntary patients; the commitment of emergency cases for three days without formal procedure; the forbidding of confinement of lunatics in jails for more than a limited period of time; the provision of home furloughs, for patients, of indefinite duration, at the discretion of the asylum physicians; and, finally, the boarding out of chronic lunatics in private families.

Dr. Peterson moved that a committee of five be appointed to examine the bill and present a report for discussion at the February meeting of the Society. The motion, after amendment by Dr. C. H. Brown, that the committee should consist of but three members, was carried.

DR. DANA thought that there should be some provision made also for the commitment of morphine and alcohol inebriates.

The President appointed as such committee, Drs. Frederick Peterson, Charles L. Dana and Ralph L. Parsons. The President becomes also a member *ex-officio*.

NEW YORK ACADEMY OF MEDICINE.

Meeting of January 2, 1890.

ALFRED L. LOOMIS, M.D., PRESIDENT, IN THE CHAIR.

ANNUAL reports were read, including that of the Committee on Library, by which it appeared that during the year the library had received 1,186 volumes, 3,541 pamphlets, and 21,000 numbers of medical journals.

The election of officers resulted as follows: *Vice-President*—Dr. R. C. M. Page; *Trustee*—Dr. Laurence Johnson; *Member of Committee on Admissions*—Dr. A. Caillé, and to fill vacancy, Dr. French, of Brooklyn; *Member of Committee on Library*—Dr. E. H. Grandin.

Mineral Waters of Aix-les-bains.—DR. BLANC, of Aix-les-bains, France, read a paper on "The Mineral Waters of Aix-les-bains and Marlioz, with Practical Considerations of their Action and Application" (see page 174).

Surgical Treatment of Peritonitis.—DR. W. GILL WYLIE read a paper on "The Surgical Treatment of Peritonitis" (see page 170).

DR. W. M. POLK, in discussing the question of operating in peritonitis, first divided the cases into those of local peritonitis and those of general peritonitis. He thought all would agree with Dr. Wylie that the chance of success in the latter class of cases was at best somewhat slight. Of course it would depend in some degree on the kind of poison which started the inflammation. Take, for instance, a general peritonitis caused by intestinal perforation, or arising from sepsis extending from the uterus after abortion or labor, becoming generally septic before the symptoms showed much severity—in such cases the results of operative interference had been anything but satisfactory.

Again, take those cases in which there was general peritonitis, yet in which, from the character of the lymph which had exuded, the septic element was not as virulent as in the other classes just alluded to, here the shock of an operation would often turn the balance against the patient. Consequently in general peritonitis all felt grave doubts regarding the result of treatment. If cleansing the peritoneum in general peritonitis would cure the case, it ought to have been proven in instances in which the inflammation had followed laparotomy, yet it was a pretty general rule to have death follow washing out the abdomen for general peritonitis following laparotomy. Yet he thought operative interference was indicated in the aforementioned cases as offering the patient the best chance of recovery.

He thought it was an excellent idea to break up the adhesions after washing out the cavity, as Dr. Wylie had advised, yet it should be remembered that usually in these cases the intestine was largely distended, and if one sought too assiduously for the seat of the difficulty he would be likely to have trouble from protrusion and great increase of shock. He would be disposed to use iodoformized gauze (not saturated) for the drain instead of a drainage-tube.

Seeing that the outlook was not favorable under any circumstances in general peritonitis, it seemed to him that the solution of the problem was to anticipate the general implication of the abdominal contents by an early incision. Here again, the cases being those of local peritonitis, should be divided into two classes, those which originated from perforation of some portion of the intestinal or digestive track, and those which arose from some difficulty connected with the uterus or its appendages.

As a sample of the first class, we might consider cases of appendicitis. Being called to a case, the physician would be able to recall instances of spontaneous recovery. On the other hand, he would remember cases in which the condition had become encapsulated and formed a local abscess. This abscess perforated, or was opened by the knife, sometimes as late as the tenth day. But in other cases the local symptoms were followed promptly by those of general peritonitis, and nearly always terminated fatally. In view of the fact that an exploratory incision performed with the precautions exercised to-day was attended with very little danger, he thought we were justified in laying down the general proposition that in all cases of local peritonitis falling under the first class an exploratory incision should be made.

In the second class, if the local peritonitis followed a labor or abortion, it was likely to become general and cause death. Here he thought the patient was given the best chance by opening the abdomen and seeking to remove the infectious matter. But where the local peritonitis was due to gonorrhœal infection, or to traumatism inflicted upon the uterus by the use of the sound, etc., clinical observation had shown that usually there was a minimum amount of sepsis, the peritonitis remained localized from first to last; it might resolve, it might go on to the formation of a pelvic abscess. If the abscess perforated it rarely involved the peritoneum. In these cases he would not make an exploratory incision unless there were indications of the case becoming one of general peritonitis.

DR. A. G. GERSTER said the subject was so vast that he would attempt to speak of only a few points. He thought wider observation would be necessary before we could formulate as precise indications as Dr. Wylie would do. He wished to state, in a general way, that the parallel drawn between local peritonitis due to affections of the uterine appendages, and that due to some affection of any portion of the intestinal or digestive tract was hardly fair. It was known that most of the cases of the former class, treated by laparotomy by the gynecologist, were of a chronic character, and in the vast majority there was no immediate danger to life. There were other considerations which induced the patient and surgeon to reach out for such a method of cure as laparotomy. Besides, there was no use of denying that laparotomy was, after all, a more dangerous operation than some constantly asserted. Another fact which had an influence on the result was, that most women operated upon with local peritonitis due to some affection of the uterine appendages were comparatively young, and their powers of resistance were still good. On the other hand, those forms of local peritonitis which the general surgeon had to deal with, starting from the intestinal tract, were generally very acute, were accompanied by great depression of the vital powers, and it was much more doubtful whether the patient could withstand the added shock of the operation.

While he wished to say that exploratory laparotomy, when done early, was not very dangerous, yet, in the class of cases which came under the care of the general surgeon it frequently was dangerous. Many of the patients were old men and old women, and an operation, which was necessary to clear up the diagnosis, though harmless in other cases, was frequently followed by death, not from peritonitis, but from the shock of the operation or some complication involving the respiratory tract or kidneys.

A recent illustrative case was given, that of an old man who had been suffering from intestinal obstruction. A tumor was noticed to develop to the right of the umbilicus. His general condition becoming worse and worse, a surgeon was finally called to take the place of the irregular practitioners. Some affection of the liver was suspected, and Dr. Gerster made an exploratory incision. The gall-bladder was found adherent to the abdominal walls, and distended. Puncture brought forth a large quantity of characteristic fluid, proving that their surmise was correct. The exploratory incision was closed. The patient had stood the operation well, but next day there was absolute suppression of urine, and he died in uræmic coma. The post-mortem showed cancer of the intestine, secondary involvement of the mesenteric glands, and extension of the disease to the cystic duct, which was occluded, and the bladder distended.

Stated Meeting, January 16, 1890.

ALFRED L. LOOMIS, M.D., PRESIDENT, IN THE CHAIR.

Donation to the Library.—The widow of Dr. Horace P. Farnham presented to the Academy ten thousand dollars as a permanent library fund, to bear the name of her deceased husband. It was accepted with a vote of thanks to Mrs. Farnham.

Change of Meeting Hour.—A resolution was adopted, changing the hour of meeting from 8 to 8.30 P.M. The President stated that the reading of reports of sections would be dispensed with, and the proceedings would begin promptly at 8.30. One of the meetings each month would be devoted to one of the sections, the sections to be called upon in turn.

The Treatment of Typhoid Fever.—DR. WILLIAM H. THOMSON read a paper on this subject. The question whether we were able to materially modify the course of an acute disease, commonly marked by a high percentage of mortality, by treatment was one of great interest. But like all important questions in therapeutics, it was very difficult of solution, though, for given reasons, apparently less difficult in the case of typhoid fever than in diseases which ran a shorter course. In studying this question we had to refer to statistics. Most cases were seen in hospital practice, and in some respects these afforded better opportunities for observing the effects of treatment than cases seen in private practice; but they had the specially objectionable feature usually of coming in late, and of occurring in unfavorable subjects. Besides, in Roosevelt Hospital, each physician's service continued but two months at a time. The reader analyzed the number of cases recorded as cases of typhoid fever, in the Roosevelt Hospital, from 1881 to 1889, inclusive. Total number, 379. Total deaths, 69, or 18.2 per cent. Of these deaths, however, 24 were within five days of admission. It was but fair to exclude these as having been uninfluenced by treatment, in which case the mortality would be 45, or 11.87 per cent. Of the total number, 163 entered the hospital during his term of service, which included September and October—the months when most cases of typhoid fever developed. His death-rate had been about 10.32 per cent., excluding those which died before the fifth day after admission. There was a high percentage of relapses, 24.5 per cent. There was intestinal hemorrhage in 4.9 per cent.

The Food.—His special endeavor in the treatment of typhoid fever was to fulfil two indications: first, to properly feed the patient; second, to bring about intestinal antisepsis. In this disease there was characteristic diminution of the peptic power of the gastric glands. It had been shown by Fenwick and by Lewis, many years before, that the gastric membrane lost nearly half its bulk in typhoid fever, and also to a large extent its functional activity. Dr. Thomson consequently diluted the milk which he gave these patients one-half or more with lime-water. Besides, lime-water was no mean antiseptic. He would no more think of giving beef-tea to a typhoid fever patient than to an infant. It was very liable to ferment and cause tympanites.

Intestinal Antiseptics.—The juices of the gastro-intestinal tract had two functions to perform, those of digestion and antisepsis. He knew of but two substances which possessed these qualities when introduced from without, and yet which were not poisonous in their action. They were pepsin (he preferred the saccharated) and hydrochloric acid. These he administered freely. There was no better antiseptic in these cases than subcarbonate of bismuth. Ten grains each of pepsin and subcarbonate of bismuth, and fifteen drops of hydrochloric acid, every three hours, caused great diminution in the tympanites and promptly checked diarrhœa. He very seldom prescribed opiates or astringents, yet there was one drug reputed to be an astringent which he not uncommonly gave in typhoid fever, namely, nitrate of silver. Combined with resin or oil of turpentine, it was the best remedy for diarrhœa and chronic dysentery. One-fourth of a grain of nitrate of silver, one-fourth of a grain of morphine, ten drops of oil of turpentine, every three hours, when there was meteorism and dryness of the tongue.

High Temperature not Necessarily a Bad Indication.—His objection to all those antipyretics which belong to the coal-tar or carbolic acid series, including quinine, antifebrin, antipyrin, etc., was that they were all muscular depressants, working mischief on the heart, vascular system, and bronchial muscles. This objection did not pertain to cold employed judiciously as an antipyretic. He had since 1871 used the cold bath, also the cold pack, and more recently the cold coil, as soon as the temperature began to rise above 104° F. He had not seen much advantage in using it sooner, and none in employing it as routine treatment, for some patients never took kindly to it. In general the after-effects of cold were far more marked and permanent than any he had witnessed from the reduction of temperature by antipyretic drugs.

Calomel.—Calomel was always given to move the bowels in patients sick less than a week before entering the hospital.

Inunctions.—An inunction of the entire body was given twice a day.

Experience in the Franco-Prussian War.—DR. THOMAS E. SATTERTHWAITE had been surprised as well as interested to find how closely his own ideas of the treatment of typhoid fever corresponded with those of Dr. Thomson. In the German army, during the Franco-Prussian war, they tried cold water as advocated by Liebermeister, also quinine in large doses, and treatment by stimulation, all kinds of stimulants being tried; but at first they failed. Finally they settled down on this plan: The bowels were first moved by calomel. The nausea, vomiting, and constipation being overcome, little more was done the first week. The second week they began the use of intestinal disinfectants—muriatic acid, usually with ipecac for bronchitis. The third week they added to the muriatic acid a little cinchona as a tonic. The fourth week, when the heart began to fail, they gave light wines. They guarded against relapses by continuing liquid food during convalescence. He was not, however, a believer in the idea that the relapses were brought on by errors in diet. The evidence was that there was real recurrence of the disease. The important point in treatment, however, was proper diet. He gave milk, and diluted it with lime-water. Large quantities of fluid were called for. The main point in treatment was not to overmedicate; better undermedicate; not to overstimulate; not to give too much food.

The Simplest Antipyretic the Best.—He said the coal-tar series of antipyretics had never met with his approbation. Much of the danger of typhoid fever was due to sepsis, which arose from the condition of the bowel. Muriatic acid was a safe antiseptic and antipyretic.

Medicine will not Abort the Disease.—DR. E. G. JANEWAY referred to outbreaks of typhoid fever in the institution for the Deaf and Dumb and in the Roman Catholic Orphan Asylum, which showed that the disease might run a very mild course, or terminate in from three to five days, without medication. Had medicine been given in cases of that kind, one might easily fall into the mistake of supposing that the treatment had caused the disease to abort. We might give one or more doses of calomel in the beginning of the disease, but it was extremely doubtful whether we accomplished, by any so-called abortive treatment, what we expected, or thought we did.

Antipyretic Drugs Useful.—He had found the class of antipyretics which had been referred to as the coal-tar series extremely serviceable in many cases where formerly he used cold. This latter method of reducing the temperature was very good in its way, but often antipyretic drugs rendered the patient's condition comfortable with the least disturbance possible. If there was a weak heart, use at the same time some cardiac stimulant. He pre-

ferred digitalis, or caffein, alone, or in conjunction with camphor in some form. The latter was not only a stimulant, but also an antiseptic. He did not think it advisable to give strophanthus, for it sometimes produced diarrhœa, probably because of some impurity as at present manufactured.

Antiseptics.—These might come in where there was beginning ulceration of the bowel. Stimulants also had their place—whiskey for the poor, since it was least likely to be adulterated. Solid food should not be given until some days after the temperature had become normal.

Gives Beef-tea.—Dr. G. L. Peabody thought that beef-tea, although not a food, was useful as a cardiac stimulant and stimulant of the appetite; it required no special power on the part of the stomach to absorb it. He did not dilute milk until there was evidence that the stomach could not dispose of the pure article; he then added a little lime-water, or gave peptonized milk.

Allows some Solid Food.—He gave some solid food, as finely divided chop or steak, even before the fever had terminated, and had not known it to cause relapse or do harm. When relapses had taken place, they were due to reinfection. The patient should not get out of bed until two weeks after fever had subsided. Like Dr. Thomson, he gave turpentine when there was dry tongue and meteorism. So far, he had not been very favorably impressed with his experience in the use of intestinal antiseptics. Small doses of antipyretics had in many cases added to the comfort of the patient, but his favorite treatment was the use of cold. This had stood the test of greatest experience the world over. The best method of application was by the cold bath. The next best was the cold pack.

Statistics of Roosevelt Hospital Imperfect.—Dr. J. West Roosevelt said the records of cases of typhoid fever in Roosevelt Hospital were incomplete, and deductions based upon them not very reliable. He also gave some solid food (meat), and said it was not more likely to decompose or produce more waste material than milk.

Nitrate of Silver for Intestinal Hemorrhage.—Dr. Carpenter, of New Jersey, believed in antiseptic treatment by subcarbonate of bismuth. He had once had a number of profuse bloody passages during an attack of typhoid fever, which ceased when Dr. Thomson prescribed for him nitrate of silver. Since then he had seen seven or eight cases in which the hemorrhages were checked by this remedy, all recovering, while formerly he had lost three such cases.

How to Give Muriatic Acid.—Dr. A. Jacobi remarked that pepsin without muriatic acid was inert in these cases. A good way to give dilute muriatic acid was to put half a teaspoonful into as much water as one gave of milk (boiled) and mix the milk and water. Thus administered milk would not coagulate in hard lumps.

Camphor Hypodermatically.—Dr. Jacobi said, regarding camphor, that it was one of the most persistent and powerful stimulants, and in heart failure might be administered with advantage hypodermatically. Regarding strophanthus, he also had found it unreliable. He did not believe we could abort typhoid fever, but could often make the attack milder.

Gives Naphthalin.—He believed in giving calomel, and in the antiseptic treatment, and in this connection spoke well of naphthalin, which he administered in every case in hospital practice.

Three Causes for the Fever.—Dr. A. H. Smith thought the fever during the course of the disease might assume three types, according to whether one or another of three causes existed. The first cause was the typhoid poison proper; the second was that of septic infection through intestinal ulcers; the third, fecal infection. On this foundation he based his treatment.

Treats Cases by System.—Dr. Simon Baruch deprecated the fact that the discussion had not shown more general and systematic use of the cold water treatment.

Dr. Thomson closed the discussion.

A Reform in Artificial Infant-feeding.—Dr. August Seibert read a paper on this subject, and exhibited an improved sterilizing apparatus and nursing-bottle, and stated that the weight, not the age, of the infant should determine the amount of food to give it. He pointed out advantages of his method over those of Soxhlet and Escherich, not the least important of which was the very cheap price of his apparatus (one dollar).

On motion the discussion of this paper was referred to the Section in Pædiatrics.

SECTION ON THEORY AND PRACTICE OF MEDICINE.

Stated Meeting, January 21, 1890.

R. C. M. Page, M.D., Chairman.

Election of Officers.—Dr. Francis Delafield was elected Chairman, and Dr. C. E. Quimby Secretary, for the ensuing year.

The Physiological Treatment of Obesity.—Dr. Walter Mendelson read a paper on this subject (see p. 176).

Dr. S. Baruch said that if medicine was ever to reach the status of an exact science it would be only through the agency of such contributions as that presented this evening. Physiological facts and empirical data together must form the basis of our knowledge. The author of the paper had confined himself principally to the prevention of obesity by the regulation of the diet, and to the reduction of fat by means of high temperature and muscular activity. Voit had proved that the consumption of the nitrogenous elements is principally through the muscles. Whatever would increase the tissue metamorphosis would reduce the fat in the body. Winternitz had shown that the impression of cold upon the external surface had the effect of increasing the physiological activity of the muscles; the first impression of cold being followed by an increased temperature.

Cold Baths.—In prescribing the external application of cold for the reduction of obesity, however, it would not answer simply to tell our patients to take cold baths. Friction was required while the individual was in the water, and it was therefore necessary either to have a swimming-bath, or to make use of Charcot's douche, in which jets of water propelled by a pressure of two or three atmospheres impinged upon the surface of the body for a brief period of time. Better than either of these was the use of the vapor-bath. It had been demonstrated by actual experiment, that the increase of temperature incident to the latter, promoted tissue metamorphosis to a very marked degree. In this procedure, however (as well as all others in which hydrotherapy was employed) it was important that the treatment should be applied with intelligence and precision. As regards the Turkish bath, while it was true that during each sitting from one to five pounds were lost, it was also a clearly established fact compensation afterward occurred; so that the patient gained nothing whatever, so far as the permanent reduction of fat was concerned. But after the vapor-bath there was decidedly less compensation, and it was therefore of decided service in the treatment of obesity. The vapor-bath followed by the cold douche (in addition to the proper regulation of the diet and general attention to the hygienic condition of the patient), would, he believed, afford results that could be secured by no other means.

Turkish Baths and American "Tipple."—Dr. Baruch then referred to the luxurious habit which many of the ladies in our large cities had acquired of frequently taking Turkish baths. This had been acquired in the first instance through the desire of these ladies to reduce themselves, and once acquired it was often very difficult to get rid of. His attention had been first directed to the matter by an article in an English periodical, which described the fair leaders of New York society as frequenting the elegantly appointed Turkish bath establishments,

and often enjoying the luxury of the hot chamber followed by massage, often whiling away many hours upon oriental divans, in drinking wines, cordials, and even stronger alcoholic beverages. He was astonished by this account, he said, and believed it to be a libel upon our American women; but he determined to investigate the matter, and he had found to his surprise and pain that there was a great deal of foundation for the statements made. This he considered a serious evil, and he thought it was the duty of physicians to diminish it as far as they could. The habit could be usually broken up if we succeeded in convincing those addicted to it that the Turkish bath has absolutely no effect in reducing fat.

The Cause of Fatness.—Dr. C. E. Lockwood said that, in opposition to the views expressed in the paper, Fleming, and he believed Virchow, held that the deposition of fat was due to the dilatation of the blood vessels in the loose connective tissue. The precise cause of obesity seemed therefore to be as yet undetermined. The causes for the increase of fat in the body, he thought, might be divided into the knowable and the unknowable. First among the former was heredity, although it was a very difficult matter to explain why some individuals should have this inherited tendency. Then there were sex and age to be taken into consideration. Females were more liable to obesity than males, and in infants and persons between the ages of forty and fifty fat was apt to accumulate. In certain climates and among certain races also the same tendency was shown. Then, again, certain nervous influences appear to promote obesity, and especially the abrogation of sexual power. In certain diseases, as well, such as chlorosis and anæmia, for instance, there was often an increase of adipose tissue.

Not Depress the Vitality of the Patients.—It was therefore of great importance that we should not depress the vitality of our patients by the treatment adopted. The oxidizing power of the blood was diminished by an excess of food and the use of strong alcohol; and he thought that *all* the kinds of food taken should be gradually and uniformly reduced in quantity, at the same time that means were taken to improve the oxidizing power. It was always necessary to watch very carefully the general condition of the patient, and especially the action of the heart. Cold baths with friction he believed to be of great service. In conclusion he referred to the baths and springs of Europe, and said that, when at Carlsbad in the summer of 1887, he had been struck with the faithful manner in which patients carried out the directions given them regarding the dietetic and hygienic regimen which was so admirably adapted to accomplish the purpose desired.

Carlsbad Treatment.—The Chairman said that people went to Carlsbad for the express purpose of getting thin. Extreme caution was necessary, however, lest the treatment should be carried too far, and he knew personally of a number of cases where organic disease had thus been produced which led to the patient's death. It was essential, therefore, that the fat should not be reduced too fast, for fear of inducing grave organic disease.

Cardiac Troubles of Fat People.—Dr. Mendelson, in closing the discussion, said he was sorry that nothing had been said by any of the speakers in regard to heart disease in its relations to obesity. In cardiac troubles it was well known that there was often a tendency to obesity, though in many instances there was present simply a feeble heart. An excess of water taken into the system would throw an excess of work upon the heart, and there was therefore likely to result a faulty circulation. Hence the necessity of cutting down the amount of fluid used to the lowest possible point in individuals with feeble heart. In his paper he had not referred particularly to hydrotherapy in the reduction of obesity, as he regarded this as comprehended under the general head of exercise, upon the utility of which he had laid stress. He had one criticism to make upon the views expressed by Dr. Lockwood, and that was in regard to his advocacy of the reduction of all classes of food. This he considered the great fault of the Banting system, and, if the plan was adopted, the patient was sure to grow weak, and suffer much inconvenience. For the reasons which he had given in the paper, the great point, as far as the diet was concerned, was to increase the quantity of albuminous food, and cut down the amount of starch and fats taken.

The Epidemic of Influenza.—Dr. Louise Fiske Bryson read a paper on "The Present Epidemic of Influenza." She gave a carefully prepared historical sketch of epidemic influenza down to the present time, and stated that there was considerable ground for believing that the disease was endemic in some parts of Russia, Northern Asia, the lake region of the United States, the Caroline Islands, and perhaps other localities. She considered the affection contagious to some extent, and possibly due to a specific germ, although none had as yet been discovered. She was inclined to the opinion that outbreaks were due to certain astronomical influences which destroyed the electrical equation. At all events, the atmospheric conditions prevailing seemed to have had much to do with the causation of the present epidemic. Having described the symptoms as observed in former epidemics and at the present time, she drew a comparison between *la grippe*, epidemic cerebro-spinal meningitis, and dengue. The rate of mortality of the disease was only about 2 per cent.; but when the vast number of persons affected by it was considered the total number of deaths could not fail to be very great. There was no specific treatment. Rest in bed and perfect quiet were regarded as of the utmost importance, and alcohol was contra-indicated except in special emergencies.

Due to Infectious Germ.—Dr. C. L. Dana said that the journals had told us that the present epidemic began in St. Petersburg about the middle of November, and he believed that it was about the middle of December that the disease made its appearance in New York. In his opinion the whole course of this affection showed conclusively that it must be due to an infectious germ. If we could draw any conclusions from analogy, influenza, like other specific diseases, was caused by a specific microbe of some form or other. But if this was the case, it was manifestly impossible for such a contagion to travel from St. Petersburg to New York in the short space of one month. In order to accomplish this feat it would have to be a much more rapid traveller than any known form of contagion. We were, therefore, forced to a second conclusion, viz., that the germ has been in this country. The microbe of epidemic influenza was not a thing borne by the wind or carried by individuals, as the cholera germ was, but it was distributed throughout the world. There seemed to be concerned in the production of this disease, further, some epidemic influence, whether telluric, electric, or of some other sort; although the speculations on this point had not as yet proved very fruitful. He understood that in Vienna it had been claimed that the specific microbe of *la grippe* had been found, although it had not as yet been proved to be capable of reproducing the disease. He did not believe, however, that this important discovery had yet been made.

Dr. Dana's Own Experience.—Dr. Dana then proceeded to speak of his own experience as regards the nervous manifestations of the present epidemic. He said that a Russian authority had divided the cases into three classes, nervous, catarrhal, and gastric. As far as he had been able to learn, the catarrhal and gastric varieties had been met with here, but the purely nervous form did not seem to have appeared, or at least to any noticeable extent. He had met with one case in which there was no chill (though some chilly feelings) or fever, and no catarrhal trouble, but in which almost the only symptom was excessive weakness. He had seen one patient in whom mania appeared after *grippe*, and another in whom encephalitis developed. In the newspapers also several cases had been reported in which mania accompanied the disease. In one case which he saw facial paralysis occurred, and in a

child there were symptoms of polio-myelitis. He believed that in this instance, however, there was nothing more than a congestion of the spinal cord caused by the epidemic influence. He had met with a good many cases of facial neuralgia, but they all seemed connected with the affection of the nasal passages. The most characteristic nervous phenomenon of the epidemic was the prostration so commonly noted, and this he believed to be the effect of the specific poison of the disease upon the heart, as was the case in other zymotic affections. This would explain why the cardiac stimulants proper were more efficient than agents like alcohol, quinine, and iron.

The Ages of Those Attacked.—Dr. W. P. Northrup spoke of the ages of the patients attacked. In the New York Foundling Asylum, where there were between seven hundred and eight hundred inmates, not a single diagnosis of influenza had been made among the children under two years of age. Some of them which were wet-nursed by women suffering from the disease fell away a little, and occasionally there was a moderate attack of diarrhœa among them, but this was all. Among the "run-abouts," however, children from three to five years of age, something like fifteen or twenty per cent. suffered. The attack was usually characterized by moderate febrile movement and more or less bronchitis; but all the children rapidly and completely recovered. Almost the entire number of those affected came down with the disease within the space of two or three days. After that there were but two or three sporadic cases. It was noticeable that there were more than the usual number of pneumonias in the house at this time of the year; but, on the other hand, the disease was less fatal than usual.

Among the adults in the establishment who were affected with influenza all the severe cases occurred in those between the ages of eighteen and twenty-five. Of the entire number of inmates who were from two to twenty-five years of age, about eighty per cent. had the disease; though many of the cases were very mild. In one case there was a well-marked symmetrical erythematous eruption. In this instance the temperature rose to 103° F., there was green vomiting and angina, and the whole attack closely resembled scarlet fever. Among the young women there were several severe cases of pneumonia and one case of Bright's disease. One curious feature about the epidemic in the Foundling Asylum was that all the wards were visited by it except one. In this ward there were sixteen "run-abouts," six nurses, and numerous infants; but not a single case occurred there, although there were many cases in the wards just above and below it. It was also worthy of note that in the Maternity none of the women awaiting confinement were attacked.

Fifty Old Ladies Escaped.—Out of fifty-two old ladies at a Home where Dr. Northrup attends only two suffered from the influenza. These two cases were of moderate severity, but typical in character. Among the attendants at this institution six out of fourteen had the disease and were quite sick with it. In private practice he had seen one case with the eruption. It was a papular erythema, symmetrical on the two sides of the body, and attended with a great deal of itching and burning.

Treatment.—As to the treatment, he desired to say that he had not used one grain of antipyrine among his patients. The reason for this was the unfortunate experience which he had once had with the drug. In this instance he prescribed fifteen grains of it, and it produced extreme depression, so that the patient became pulseless, and he was much alarmed. Notwithstanding this untoward effect, the patient was willing to take five grains of antipyrine afterward, and in this quantity it gave rise to a troublesome and painful urticaria and to such distressing dyspnœa as he had never seen except in occasional cases of Bright's disease.

The Eye Symptoms.—Dr. T. R. Pooley said that, when he was himself affected with the disease, he took great interest in studying the eye-symptoms in his own case; and he found that at a recent meeting of the Ophthalmological Society a great many of those present had noticed the same symptoms in patients suffering from influenza. Dr. Hackley, who, in addition to being an oculist, had an extensive general practice, had found them present in a very large percentage of cases. There was a sense of pain in the eye, particularly upon movements of the organ, and very often a deep-seated pain in the orbit. In his own case there was very marked asthenopia, which was the more noticeable from the fact that ordinarily he did not suffer from asthenopia at all. The symptoms referred to were only transient, and it had not yet been shown that any permanent disease of the eye ensued. He supposed the trouble to be simply a weakening of the ocular muscles, such as was met with in other diseases producing exhaustion. In his own case he could feel that there was paresis of accommodation. He had met with only one or two cases in which the conjunctiva was affected, and in these he thought it very possible that the patients had had catarrhal conjunctivitis before they were taken with the influenza.

He had of late seen an unusual number of cases of acute inflammation of the middle ear, and they all seemed to be attributable to the effect of the epidemic and to be connected with catarrhal inflammation of the throat and air-passages. In such cases examination showed hyperæmia of the drumhead, and in some instances there was perforation of the latter.

The Ear Troubles.—Dr. O. D. Pomeroy said that he had met with a larger number of cases of ear-trouble than of eye trouble as a result of the influenza. Both these classes of affections seemed to occur some little time after the disease had spent its force. At the Manhattan Eye and Ear Hospital he had some six or seven cases of catarrhal conjunctivitis, and one case of very severe ulceration of the cornea. In one case not in his own clinic there was complete ecchymosis of both eyes, such as was sometimes observed in whooping-cough, where it was no doubt due to rupture of the blood-vessels from the violence of the cough. In the case in question, also, the patient suffered very greatly from cough. All the principal symptoms alluded to by Dr. Pooley had been likewise noticed by himself.

As regards the ear, purulent otitis of an acute character was quite common. In this the discharge was very great, and spontaneous rupture of the drumhead not infrequently occurred. There appeared to be about four purulent cases to two catarrhal ones. The purulent cases were apt to be very violent, and in one instance that he had met with there was mastoid periostitis. The ear symptoms seemed on the whole to be more frequent and of a graver character than was the case in scarlet fever; and they were all probably caused by the spreading of an inflammatory process from the throat through the Eustachian tube, and thus affecting the middle ear.

The Chairman spoke of the tendency of epidemic influenza to be complicated with capillary bronchitis and pneumonia, and said that he himself and others of the Section would like to hear from Dr. Francis Delafield what kind of pneumonia was met with in connection with the present epidemic.

Frequency of Bronchitis and Pneumonia.—Dr. Delafield said that he supposed every one had been struck with the frequency with which both bronchitis and pneumonia had occurred. As regards the bronchitis there were two things which had repeatedly attracted his attention. The first was the very satisfactory way in which the apparently very bad cases got well. Often there was great difficulty of breathing, with considerable rise of temperature, and expectoration of blood as well as mucus. Yet he had been surprised to see how well such patients had done, and in what a comparatively short time improvement began to take place. The second point was the large number of individuals who, while they had a general bronchitis, as far as the large tubes were concerned, and a localized bronchitis involving the smaller tubes, yet remained free from any implication of the lung-

tissue. This class also, in his experience, had done well.

As to the pneumonia, he thought that every one must have been impressed with the fact that almost all those who were attacked by pneumonia had with it a great deal of bronchitis. In these cases of pneumonia there was a considerable difference, and he had observed altogether four classes among them.

In the first the cases were very mild. The temperature did not run high and there was very little dulness on percussion. There were some subcrepitant râles over a portion of the lung, but these cleared up within a few days.

In the second class of cases the patients did not seem to be very ill, and did not have a very high temperature, but they had considerable bronchitis and perfectly well-marked consolidation of one lobe for one or two weeks; and after that they got well.

The third class was composed of those who had fully developed consolidation of the lung which went on for quite a long period. The temperature rose perhaps to 104° F., and did not go down. After ten, or even twenty, days it would still be found that the consolidation had not cleared up. In many instances, however, after this very long period, the lung did clear up, the temperature fell, and the patient got well.

The fourth class was made up of the very bad cases. In most of these, together with the pneumonic consolidation, there were evidences of a great deal of bronchitis. The action of the heart was poor, and there were collections of blood in the veins. When this condition had been established the heart's action grew very rapid and feeble, and expectoration became suppressed. Such patients seemed to do badly, no matter what course of treatment was pursued. Some seemed to be relieved for a day or two, and then the grave symptoms all came back again. In a smaller number death occurred as in ordinary lobar pneumonia.

Dr. Lockwood spoke of the great usefulness of antipyrine in relieving the neuralgic pains so constantly met with in *grippe*, and stated that for the cough he had found muriate of ammonia, in combination with other remedies, of the greatest service.

Dr. Wood said that he thought a note of warning ought to be given in regard to the use of antipyrine. This, he was convinced, was an agent which was quite capable of complicating the disease very seriously a little later on in its progress, if it did not at the outset. Its administration was apt to be followed by cold perspiration and a relaxed condition, and, if much bronchitis was present, it was liable to produce great depression unless employed with extreme caution.

Navy News.

Official List of Changes in the Medical Corps of the United States Navy for the week ending February 8, 1890.

Jones, W. H., Surgeon. Ordered to the Swatara.

Hudson, A., Medical Director. Died February 7th, at Mare Island Hospital, Cal.

Salt for Facial Neuralgia.—At a recent meeting of the Edinburgh Medico-chirurgical Society, Dr. George Leslie reported between thirty and forty cases of facial and other neuralgia, cephalalgia, odontalgia, etc., which had been cured, in most instances instantaneously, by insufflation of powdered common salt through the anterior nares. The salt was either "snuffed" or blown up the nostrils. He had been unsuccessful in only two cases; both of these were cases of old standing, which had been treated frequently by morphine injections. In one of them excision of the nerve had been practised.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending February 8, 1890.

	Cases.	Deaths.
Typhus fever	1	0
Typhoid fever	9	4
Scarlet fever	88	10
Cerebro-spinal meningitis	3	2
Measles	80	10
Diphtheria	123	34
Small-pox	0	0
Varicella	1	0
Cholera	0	0

Babies Born with Measles.—Dr. C. F. Darnall, of West Union, Ia., writes: "Under discussion of babies being born with measles, I report: March 17, 1888, I was called to see Mrs. R——, a young German woman, seven and a half months pregnant, who was sick with measles, and was at the third day of the eruption. She was coughing violently and suffered some pain in the lower abdomen. Knowing well that she might be confined, I took what precautions I could against that, and promised to call the next day. When I reached her the next afternoon I was just in time to deliver the placenta, apply the bandage, and superintend the care of the child. It was a small, puny girl, covered with the same eruption as the mother, and lived two days, and then succumbed to capillary bronchitis. The mother made a good recovery."

Not Snake-bites.—Dr. G. L. Pritchett, of Fairbury, Neb., who has lived all his life in the region of rattlesnakes, says that the first case related by Dr. Thomas, of Alexandria, Neb., only proved that the treatment was not persisted in sufficiently long, and that the second case was evidently not a snake-bite at all, but merely one of traumatic erysipelas.

Bromine in Diphtheria.—Dr. H. L. Manchester, of Pawlet, Vt., writes: "Will you allow me to correct a mistake which Dr. Ayer seems to have made in regard to my mention of the use of bromine in diphtheria. I did not lay claim to priority in the matter at all. As a matter of fact, I used it first because Professor W. H. Thomson, of the Medical Department of the University of the City of New York, strongly urged it upon the class of '79, of which I was a member. I do not remember of reading anything regarding its use in this disease recently, and I wrote to call up the matter and ascertain if it had fallen into general disuse. It seemed a valuable remedy, and I did not wish those who are annually starting on the road to fame and wealth, by practising 'physic,' to lose sight of it. I confess ignorance of Dr. Goldsmith's articles on this particular use of bromine, although aware of the value of his labors with it in other fields. I desire to relieve myself of the absurd position of claimant of a new disinfectant in diphtheria by mentioning bromine in that capacity."

French and Foreign Doctors.—American doctors already established in France, or who may wish to pitch their tents there, are deeply concerned in the bill recently laid before the Chamber of Deputies by M. Chevandier, of the Drôme. That bill, which will soon come into discussion, provides for new regulations in regard to the licensing of native physicians, and also in regard to the admission to practice in France of foreign doctors. It is known that the professional exercise of medical talents is not free in France. It is permitted only to those who have studied regularly at the "Faculties of Medicine," which are themselves governmental institutions placed un-

der the directorship of the Minister of Public Instruction. Those who have studied for five years at those faculties, and have successfully passed the final examination, are officially recognized as doctors. Those who have only followed for two or three years the classical course of the faculties are recognized merely as "officers of health," and usually practise in small towns or villages. The new bill requires the abolition of that class of medical men. But it is unlikely that the suppression will be voted; for the "health officers" in France are good physicians. The country is already not too well provided with that class of useful men, and the number of them is decreasing, instead of increasing, proportionally to the population. In 1847 there were in France 18,099 physicians of both degrees; at the last census, in 1881, there were only 14,846. In some out-of-the-way places, like in the Department of the Lower Alps, there was only one physician to each 12,000 inhabitants. The second proposition in M. Chevandier's bill relates to the conditions to be required from foreign doctors previous to allowing them to practise in France. The rule was formerly, and is still now, that a foreign doctor having his diploma from a foreign medical university, school, or faculty, could practise in France, provided he should be allowed to do so by the government, which usually granted the said permit to be issued on a mere application, by the Minister of Foreign Affairs. The new bill requires that such permits shall be granted hereafter only after the foreign applicant shall have passed successfully through an examination before a French "faculty of medicine," on the same conditions as those imposed on the French medical students. In fact, M. Chevandier's bill considers as naught the diplomas obtained from foreign faculties; and this second portion of the bill may be voted more easily than the first. In many parts of the country, and especially in the watering-places and pleasure resorts, foreign doctors, mainly Americans, are driving a hard competition with their French colleagues, whose profession numbers sixty-two members in the Chamber of Deputies. It cannot be denied that the good renown of American physicians has greatly suffered from the recently discovered bogus medical universities in the United States, and from the knowledge that bogus diplomas were ground out by the bushel by bogus professors and doctors.—*New York Tribune.*

Scratching the Back for Intermittent Fever.—Dr. Alois Fénykövy communicates to a Vienna medical journal an account of some observations made on the treatment of intermittent fever by means of friction of the back along the spine. Many years ago, while at Nisch with his regiment, there occurred so many cases of intermittent fever that the stock of quinine was becoming exhausted, and, in order that the patients might not be entirely without some sort of treatment, it was ordered that they should be rubbed twice a day along the spine with simple ointment. The day after this order had been given it appeared that the usual attack had not come on; accordingly, since that time Dr. Fénykövy has very frequently employed this treatment, and usually with marked success. Indeed, he says that three-fourths of his cases have done very well without any quinine at all.—*The Lancet.*

Gaseous Cysts of the Neck.—Dr. L. H. Petit has published a monograph on these cysts, known to previous authors as "aëroceles," "bronchoceles," "laryngoceles," or "tracheoceles." The author concludes that there exist in the neck air-holding tumors produced by a communication between the larynx or trachea and the cellular or interfascial spaces in their neighborhood. The predisposing causes may lie in normal structures, the ventricles of the larynx or the membrane uniting the tracheal rings posteriorly, or in anomalies of those structures, or in pathological changes in the mucous membrane or cartilages, or in wounds of the trachea. Violent coughing or straining may set up a gaseous cyst. These cases begin either by a direct hernia of the laryngeal or tracheal mucosa, or by passage of air through a rent or ulcer in the same into the adjacent tissues. Hence, a gaseous cyst may have a distinct lining membrane, sometimes consisting of the herniated mucous membrane, or may lack any true wall, as in ordinary emphysema of connective tissue. The circumscribed type sometimes develops suddenly, sometimes grows suddenly long after development, and in other cases increases slowly but steadily from first to last. Whenever the communication with the air passage closes early and completely the gaseous tumor remains as a rule stationary. When the communication remains unobstructed the tumor feels soft and flaccid during rest, but enlarges rapidly during expiration, coughing, or straining, diminishing on compression, deep inspiration, or forced extension of the head. The tumor is resonant on percussion and causes modifications in the voice. The skin remains unaffected. Dr. Petit, contrary to previous writers on the subject, holds that certain forms of gaseous tumors may undergo spontaneous cure. He refers to the variety which appears suddenly at one effort and without any chronic disease of the respiratory tract or abscess in the surrounding parts. The other varieties remain stationary or slowly increase. Dr. Petit also holds that in some cases an operation similar to the radical cure of hernia might be attempted; but compression from without would be less hazardous. In other cases, when fits of suffocation occur frequently, tracheotomy is indicated under certain precautions.—*The British Medical Journal.*

A Case of Rupture of the Right Phrenic Nerve followed by Instantaneous Death.—The following case is reported in the *Indian Medical Gazette.* A porter, while carrying a bag, fell on his back with the bag on the front of his thorax. He was picked up immediately but was dead. Dr. Mackenzie who performed an autopsy states that the body was that of an adult native male of about forty years of age. It was well nourished and no external mark of violence could be detected on it. The lungs were found to be highly congested. The heart was healthy. The right cavities of the heart were full of dark fluid blood. The left cavities were empty. The liver, the spleen, the kidneys, and the vessels of the brain were congested. The stomach, the intestines, the bladder, the larynx and trachea, the œsophagus, and the substance of the brain were healthy. No bones were fractured. The only injury which could be detected was a rupture of the right phrenic nerve in front of the root of the right lung. He gave it as his opinion that the deceased died from the rupture of this nerve. During a nine years' medico-legal experience he has observed seven deaths from precisely similar accidents, in five of them the cause of death was ascertained to have resulted from fractures of one or more of the cervical vertebræ with injury of the spinal cord, and in two from shock following fractures of the sternum. He has not been able to find a case exactly similar to the one given above in any medical work. The only case he found regarding injuries to the phrenic nerve was in volume i., at page 605, of "Erichsen's Science and Art of Surgery" (seventh edition). It is as follows: "The division, however, of the respiratory nerves on the one side only, or even of one of them, would in all probability be fatal in man by interfering with the proper performance of the respiratory act. In a case with which I am acquainted, while the phrenic nerve was divided during ligature of the subclavian artery, death resulted in a few days from congestion of the lungs."

Venesection in Lead-poisoning.—Dr. Wilhelmi, of Güstrow, strongly recommends that in cases of lead-poisoning a small quantity of blood should be taken from the arm. He has practised this treatment in twenty-five cases, and speaks warmly of the success he has met with. the patients in some cases expressing themselves as greatly relieved immediately after the operation, and the affection taking a marked change for the better from that time.—*The Lancet.*

The Specialist and the Burglar: A Fable.—A burglar entered the office of a specialist, bent on plunder. The specialist saw him, walked him to a chair, sprayed him, prodded him, sprayed him some more, had ten dollars out of him, and commanded him to "call again to-morrow," before the burglar could formulate an excuse for his intrusion into the doctor's office. Moral: It is better to be a specialist than a burglar.

There is no Harmless Hypnotic.—Dr. Hutchinson says: "I have recently met with several cases of insomnia due to over-taxation of the American nervous system, and have been requested to prescribe some drug that would be effective to procure sleep, and be at the same time harmless. No such drug exists. There is no medicine capable of quieting to sleep voluntary life that has been working ten hours at high pressure, except it be more or less poisonous. Consumption of chloral, bromine in some form, or opium, has increased in this country to an incredible extent, is still growing, and a large number of Americans go to bed every night more or less under the influence of poison. Sleep thus obtained is not restful or restorative, and nature sternly exacts her penalties for violated law, more severely in these cases than in most others. Digestion suffers first; one is rarely hungry for breakfast, and loss of morning appetite is a certain sign of ill-health. Increasing nervousness follows, until days become burdens, and poisoned nights the only comfortable parts of life."—*American Magazine.*

The Gastritis of Phthisis.—Digestive derangements, such as anorexia, epigastric discomfort, and vomiting, not infrequently form some of the most troublesome symptoms with which the practical physician has to deal in cases of pulmonary phthisis. And while the clinical aspect of dyspepsia in phthisis has been the subject of more or less attention from Rosenthal, Klemperer, and others, the question from the stand-point of pathological anatomy has been somewhat neglected. The only monograph of importance that has appeared since the older writings of Louis, Wilson Fox, Fenwick, and others, is by Margan, in France, who has in many respects given an able account of the subject both from a clinical and from a pathological point of view. The most recent contribution is from the pen of Dr. Schwalbe, who, bearing in mind the importance of post-mortem changes, took the precaution to remove the stomach in his twenty-five cases very shortly after death (generally one to two, never more than five hours after). He was thus able not only to study more satisfactorily the naked-eye appearances, but also to enhance considerably the value of his histological investigations. In each case he examined the fresh tissue microscopically, and removed portions from different regions of the stomach for subsequent histological investigation. In only two cases did he meet with dilatation of the stomach, and he considers that ectasia ventriculi must be regarded as a rare complication of phthisis. As to the state of the mucous membrane itself, except that it occasionally looked slightly thickened and swollen, it presented, in the great majority of the cases, no morbid appearances worthy of note. The exceptions were one case in which amyloid infiltration was marked, and here the mucous membrane presented multiple but small erosions scattered over the surface. In another case it was decidedly opaque and mottled in yellowish patches; in a third, tubercular ulceration was found near the pylorus. In no case was a thinning or atrophy of it met with, and only rarely was it noticed coated with tenacious mucus indicative of a catarrhal condition. The results of histological examination showed that in five the organ was normal, in fifteen interstitial gastritis was found, but for the most part slight or moderate in degree; of the remaining five cases, amyloid changes were found in one, both in the mucosa and submucosa, and marked parenchymatous degeneration of the glands in four. The interstitial gastritis was invariably in the form of a small-celled infiltration of the intertubular stroma, and in no instance had it developed into fibrous tissue so as to cause atrophy of the mucosa. But in cases where it was more obvious, secondary changes in the tubules were also observed, namely, cystic dilatation and alterations in the epithelial cells. Schwalbe maintains that it is only in cases where the tubules have undergone alterations in position, form, and size, that any definite pathological significance can be attached to the accompanying cellular changes. The four instances where the parenchymatous were the only changes noted must be regarded as examples of simple parenchymatous gastritis (Virchow), with extensive fatty degeneration of the cells. He was not able to trace a metamorphosis of the two kinds of cells one into the other (for example, the principal into the parietal, and *vice versâ*); nor did he find a perceptible or constant diminution in the parietal or peptic cells, so that in this respect he does not confirm the results of other observers. Coming now to the important question, how far these structural changes are responsible for the functional disturbances, he differs materially from previous writers. He is of opinion that the interstitial gastritis which occurs in the later stages of phthisis is seldom of such extent or importance that any noteworthy impairment of function can be ascribed to it. It never reaches the intensity of that atrophic form in which nearly all secretory power is lost, as Fenwick, Ewald, Rosenheim and others have shown in idiopathic disease of the stomach. Even in the cases of simple parenchymatous gastritis it is doubtful whether the hydrochloric acid production is interfered with to any material degree, for in a case of acute yellow atrophy of the liver, where no diminution was noted. Rosenheim found extensive fatty degeneration of the tubular glands. He had seen both parenchymatous and interstitial inflammation in persons who never complained of dyspeptic symptoms, and, on the other hand, patients have complained severely of dyspeptic symptoms, in whose stomach there was little or no inflammatory change. Accordingly, he holds that it is not possible to establish any constant relation between the pathological conditions and the clinical signs. At the same time he does not state that such changes as he has described are entirely without effect, but believes other important factors must be taken into account to explain the dyspeptic symptoms of phthisis. These are anæmia, nervous depression, atony of the stomach, and vitiation of taste from constant expectoration of foul sputum. Regarding the etiology of the gastritis, Schwalbe believes it develops in the later stages of phthisis during the formation of vomicæ, and is to be attributed to the absorption of toxic substances resulting from the necrosing lung parenchyma, which enter the blood and set up a gastritis much in the same way as they may excite a nephritis. —*The British Medical Journal.*

Iodoform in Chronic Metritis.—Drs. Roux and Schnell, while admitting the value of curetting in certain cases of metritis, believe that a more simple treatment often yields good results. They recommend intra-uterine dressings of iodoform, and affirm that the treatment by iodoform has already given good results, both in obstetric and gynæcological practice. There are two ways in which iodoform may be employed—in pencils and in injections. The pencils are prepared by incorporating the iodoform with a mixture of gum arabic, gum tragacanth, and butter of cacao, or gelatine. For butter of cacao the proportion of iodoform should be one in seven; with gelatine two parts in eight. The crayons prepared with butter of cacao are hard and brittle; those made with gelatine are soft and elastic. They are introduced into the uterine cavity by means of polypus forceps, directed by two fingers of the left hand in the vagina. The injections may be made by forming an emulsion of iodoform with oil or glycerine and solution of gum tragacanth. This emulsion can be injected through a sound by means of a Pravaz syringe. All instruments should be disinfected by boiling them in water.—*Journal de Médecine de Paris.*

Rheumatism in Japan.—*Apropos* of the suspected influence of the climate of Japan in the causation of rheumatism and neuralgia in resident foreigners, it is interesting to note that horses imported into Japan from China and other countries are soon more or less disabled by rheumatism.—*Sei-I-Kwai Medical Journal.*

The Bones Library is a new industry in Chicago. Here is a description of the interior, furnished by a local paper: "The lower floor of the cottage, consisting of two large rooms and one small one, was completely filled with articulated skeletons and osseous human fragments of all descriptions. The skeletons were suspended in glass cases ranged along the walls and protected by a wooden railing about three feet high. A sort of wooden trough along the top was filled with skulls of all sizes, looking like a ball-roost in a bowling-alley. Long tables down the centre of the rooms were piled high with jaws, sternums, cervical, dorsal, and lumbar vertebræ, and other minor details. Collar-boxes, full of toe and finger joints and teeth, were stowed away on shelves under the tables, within easy reach. At the lowest calculation there was at least a car-load of bones in the two rooms. The ghastliness of the place was greatly relieved by some placards on the walls, bearing such cheerful inscriptions as 'Single Ribs, Fifteen Cents per week; with Vertebræ, Twenty Cents;' 'Positively no New Bones issued until Old Ones are Returned;' 'Double Charges will be Collected on All Bones kept over Specified Time;' 'Holders of Skeletons will be held Responsible,' and a host of similar announcements. Seated at a small desk in the midst of this chaotic resurrection was a plump, handsome little woman of twenty-five, nonchalantly picking her teeth with a bit of splintered rib, and wearing an air of happy self-possession that was absolutely refreshing."

Some Statistics on Revaccination.—Considering the vast importance of perfect immunity from small-pox, I herewith submit some statistics on the subject of revaccination, carefully collected by myself during some public work of this kind in the months of July and August of 1888. The importance of more or less frequent vaccination, regardless of previous ones, seems to be well pointed out, as these were done during an outbreak of small-pox and in people who thought themselves protected, and submitted to it in most cases under protest. It is true all my cases were negroes, and knowing their susceptibility to small-pox, and probably to vaccinia also, the figures may seem too high to apply to the white race, but their importance is indisputable. All of them had been vaccinated five years before during an epidemic, and had large scars, many of which I thought to be simply from septic matter having been introduced at the time of operation, or from the same subsequently introduced by scratching or otherwise. Some, about half, had typical marks, and it was among these most of the failures occurred. I submit the following figures: Total number of revaccinations, 240; failures, 120; successes, 83; unknown as to result, 37. Thus we see out of 203 cases in which the result is known, there are 83 successes as regards 'taking,' or 40.8 per cent. I add a few remarks, which can never be too often impressed on the mind of the vaccinator. I found many large, smooth cicatrices, some the size of a silver dollar, bearing no, or but little, resemblance to the true scar of vaccinia; these cases were almost invariably successful, and, as stated above, were, I believe, either from septic matter introduced as virus or from dirty instruments, or more probably from failure to wash and cleanse the arm of the subject before operating. If the latter precaution was strictly followed, the instrument cleansed before and after each operation, and pure, unspoiled lymph used, the arm being protected from dirt until the drop of blood and virus dries over the insignificant lesion produced, I believe the ancient prejudices, often founded on the fact of a very much inflamed or an erysipelatous arm, would soon die out. None of these cases were inflamed beyond that natural to the vaccinia, except in two or three, and these were directly traceable to infection from dirty finger-nails. No account was taken of ages, but they ran all the way from the "cradle to the grave." Let me add my protest against the small price paid per capita for such practice, which must necessitate rapidity, and consequently carelessness of work, while it often prevents competent physicians engaging in it at all; and also against the filthy manner in which it is then usually done, the operator scratching through a layer of dirt, often perceptible to the naked eye.—D. G. Winston, M.D., Glasgow, Ky.

Masturbating Sodomy.—Dr. J. Frank Walker, of Florida, Ala., writes: "On December 17, 1889, I was called to the office of Dr. P. I. Price, of this city, and consulted about the removal of a foreign body from the lower bowel of his patient. Introducing my arm half-way to the elbow, I felt with my hand a large oval object, and succeeded in bringing it down within a few inches of the sphincter ani. After many futile attempts with my hands and various instruments (knives, blunt hooks, etc.), I finally succeeded in locking a small pair of obstetrical forceps around, and extracted a turnip, measuring nine and one-half inches in circumference and eight and three-fourths inches around top and base. Thinking it singular that such an object should be found in this situation, we obtruded ourselves into our patient's confidence and gained in substance the following: Aged thirty-three; when a boy, patient began introducing partly into rectum apples, turnips, and other round or oval objects. This practice gave him a peculiar pleasure, such as sodomists experience, I suppose. Eleven years ago (at age of twenty-two) he married, and for five years left off the vice to some extent only to return to it again. On December 16th, while handling a turnip of unusually large size, it slipped his grasp and was carried by the contractions of his sphincter out of his reach. He had walked ten miles for surgical assistance when seen, and was suffering intense agony from the swelling, inflammation, etc. Even this experience would not induce him to promise to leave off this the most disgusting of vices, masturbating sodomy."

Some Curious Events, partly Medical.—The *Western Medical Reporter* is responsible for the three items which follow: Sam Hornsley and Sylvia Cody, both colored, the former aged seventy-five years and the latter seventy, were married recently in Hephzibah, Ga., by O. G. Tarver, at the store of E. J. Tarver. John McClellan, of Jeffersonville, Ind., was bitten by a mosquito, Sunday. Wednesday he was seized with convulsions, his right side became paralyzed, and he was not expected to live. Mrs. Hiram Sneal, of Malad, Idaho, one day last week gave birth to six children, three boys and three girls, weighing eight pounds altogether. If this Malad-y should become contagious Idaho will soon be entitled to admission as a State.

Medical Students in France.—According to the statistics of the French Department of Public Instruction, recently published, the number of students of medicine has nearly doubled in the last ten years. In 1878 there were only about three thousand students, whereas in 1888 the number inscribed was between six and seven thousand. It is a curious fact, however, that there has been but a very slight increase in the number of graduates during the past twenty or more years. In 1866 the number receiving the degree of doctor was 520, ten years later it was 610, and only once since that time have the figures been above that, but several times have been below. The number of officiers de santé (a minor grade of medical practitioners) fell off from 200 in 1878 to 80 in 1888.

Labels for Poisons.—A bill is about to be introduced in the Legislature by Assemblyman Usher, compelling druggists to have printed on the labels of bottles containing poison, the proper antidote.

THE ANATOMY OF THE THORAX AND LUNGS IN RELATION TO CERTAIN POINTS IN PHYSICAL DIAGNOSIS.[1]

BY J. WEST ROOSEVELT, M.D.,

VISITING PHYSICIAN TO BELLEVUE AND ROOSEVELT HOSPITALS, NEW YORK.

ALTHOUGH so much has been said and written about physical signs and their causes, great difference of opinion exists in regard to the subject. If ever it be possible to establish physical diagnosis upon a rational basis, this basis must rest upon anatomical study. Both the anatomist and physiologist usually look upon the thorax and lungs from a point of view so different from that of the physical diagnostician, that their studies are of little value to him. The first is apt to be too much interested in details of structure, the second in questions of function. The physical diagnostician, must regard the anatomy and physiology of the chest as he would the component parts and action of a piece of machinery, any disarrangement of which can be appreciated by the senses. As most of the derangements are appreciated by the ear, the acoustical properties of the thorax are of much importance.

In this paper I regard the thorax and lungs purely from this mechanical stand-point. I venture to bring forward the subject not so much that what I have to say is new, but because I believe it to be true. Every sign mentioned has been observed by myself, and the anatomical statements are based upon dissections, corrosion preparations, or sections made by me. I do not know that any observation is original; I know that many are not. I have tried to study objectively—to see what *is*, not what has been said to be. How far I have succeeded I do not know. I hope that, at least, I may present some of it in a new light. This is my only excuse for writing.

Much of the confusion regarding physical signs has been caused by the use of incorrect diagrams. The usual diagram of the air-vesicle and terminal bronchus, for instance, is preposterous. The average diagrams representing pleural effusions are absurdly incorrect. Both have had their influence in producing false ideas of physical diagnosis, since they give false impressions of the mode of production of physical signs. This is no theoretical matter. A man who does not have a clear idea of physical conditions cannot progress in the study of physical signs. He who thinks that bronchial breathing necessarily indicates consolidated or compressed lung, or cavernous breathing a cavity, as many diagrams would tend to show, is not a trustworthy interpreter of pulmonary signs. The same is true, in lesser degree, of one who supposes that the level of pleural effusions is always horizontal when the patient stands, or that it usually shifts when the patient lies down, or that absence of evidences of change of level with the patient's change of position indicates pleural adhesions, or that the lung is under active pressure from fluid save when the quantity is very great, or, finally, that the lung is compressed or contracts directly and symmetrically toward its root when fluid is present.

The air-vesicles do not in the least resemble the usual diagrams. Active pressure upon the elastic lung, until fluid is very abundant, is, as Garland has shown, impossible. The same author has demonstrated why the fluid-level does not always change with change of posture.

[1] Read before the Practitioners' Society, January 3, 1890.

That the lung cannot contract toward its root is evident when one looks at the *ligamentum latum*. Yet all the ideas mentioned are common.

The Air-vesicles.—In regard to the anatomy of the lungs, for the present purpose we are mainly concerned with the bronchial and vesicular portions. The former is better understood than the latter. The description which follows is the result of much study of corrosion preparations. It corresponds with that of Delafield, in his "Studies in Pathological Anatomy." This description (of Delafield's) has been generally discredited. Among others who doubted its accuracy was the writer of this paper. A good deal of work has convinced me that Delafield's view is correct. It may be said that there are two different ideas in vogue regarding the anatomy of the pulmonary lobule; some regard the air-vesicles as attached to the terminal bronchi like a raspberry with its interior hollow. Hence many time-honored diagrams representing fine *râles*. Others give a more elaborate description of infundibula, etc. When one looks at perfectly injected corrosion specimens, the berry form suggests itself. When the injection is less perfect, the other view seems correct. When, however, one takes a perfectly injected cast of ultimate bronchus and air-vesicles (which looks like a berry), and breaks it up (observing it with a low-power lens), it becomes evident that the interior of the berry is made up of spheroidal bodies which are attached to one another at two or more points. These are the true air-vesicles, and the important point for us in Delafield's account is that these vesicles communicate freely with one another. This they do, since it is possible to break off a number together, and then, by further breaking, to show that there are many which present corresponding rough surfaces at the line of fracture. Delafield further points out that the bronchi enter the lobules in an irregular manner, sometimes from the side, sometimes from the distant end, etc. It is perfectly easy to reconcile the two other descriptions if this view be adopted. Kölliker, Klein, and others describe imperfec injections. Those who are responsible for the usual diagrams, probably studied well-injected specimens imperfectly broken up, and also sections of lungs which seem to bear them out. Delafield describes "air-passages" which, he says, "seem to be made up of a succession of large vesicles opening into each other, or of an irregular, larger canal, made up of vesicles into which other vesicles open from all sides. These air-passages branch and anastomose. . . . They are given off from the ends of terminal bronchioles, or from the sides of small bronchi" ("Studies in Pathological Anatomy," vol. i., p. 102). In Delafield's "air-passages" we have "the infundibula," the "respiratory bronchioles," and the terminal bronchi with vesicles opening into them. The main fact which Delafield demonstrates is the communication between air-passages.[1]

The Bronchi and Blood-vessels.—The bronchi divide and subdivide, until finally the ultimate bronchioles terminate in the branching and freely communicating air-passages and vesicles. This arrangement exposes a very large surface to the air in the lobules; it also makes room

[1] The question whether or no the true respiratory portion of the lung is made up of anastomosing passages, was long a matter of dispute. The view that there is no such anastomosis is generally accepted. Thomas Williams, in the Encyclopædia of Anatomy and Physiology, London, 1859, article, Respiratory Organs, Anatomy of, p. 264 et seq., gives an excellent résumé of the earlier views about this. He also describes and figures anastomosing passages

for much elastic tissue, and it must cause a very great amount of motion in the air within the lobules and bronchioles with the respiratory movements. It is interesting to note that the bulk of the air-vesicles is always greatest where the chest motion is greatest, and that, as I demonstrated in this Society at a previous meeting, the bronchi and arteries run in such a direction that they tend only to lengthen and shorten in respiration.

The veins pursue a different course from the arteries. They lie as far as possible from the bronchi, while the arteries accompany these tubes. Their course also is more tortuous. They are surrounded by elastic pulmonary tissue, attached loosely to their walls. The mechanical advantage of this arrangement has not, I think, been pointed out. It is evident that the veins are so placed as to tend to be held open during inspiration and expiration, by the tendency of the elastic tissue to contract toward the bronchi. They are so placed as to be practically uncompressed by the atmosphere. In fact, they may be said to run always through those parts of the chest in which there is a nearly perfect balance between the contractile power of the lung and the atmospheric pressure.

Ewart, in his remarkable monograph, "The Bronchi and Pulmonary Blood-vessels," describes the course of the veins with the same exactness and detail which characterize the rest of his work. He views the veins, however, as parts of the pulmonary framework. In this he is, I think, only partly correct. He is right, as far as he goes, in looking upon the veins as part of the pleural and pulmonary connective-tissue system; but the vein only lies in, and does not form a part of, the sustentacular system, running in the latter because it is necessarily best placed, as far as possible from the centres of expansion and contraction of the lung. I cannot speak too highly of this work of Ewart. It fills a practically unexplored field of pulmonary anatomy with a thoroughness which leaves nothing to be desired. It has vastly simplified my own work, and rendered the publication of much of it needless. To it I am indebted for the first correct idea of the pulmonary vein. My view of the subject is purely mechanical, and Ewart's anatomical, hence we interpret differently.

The Attachments of the Lungs. — The structures forming the roots of the lungs are not so much concerned in holding the organs in place as is usually assumed. Far more important are the pleural folds known as the *ligamenta lata*. These broad ligaments are arranged in such a way as to fasten the lungs, for a considerable part of their inner surfaces, firmly to the vertebral column, pericardium, and diaphragm. Their folds are so separated above as to leave free room for the bronchi, vessels, etc., and so protect them entirely from injury or pressure during respiration. Except these broad ligaments, the rest of the pleuræ of the lung and thorax are interesting for our purposes in so far as they glide over one another.

The Thorax and its Contents.—The thorax is an expansible cavity, partly enclosed by rather rigid walls, composed of bone, connective tissue, and muscles, partly by the very elastic diaphragm. The cavity is divided into two compartments for the lungs by the mediastina and the pericardium contents. These structures make a fairly rigid column, attached above to the deep neck fascia, below to the diaphragm. The central parts of the latter are thus held nearly motionless at all times.

The chest moves in respiration in such a way as to enlarge or diminish every diameter (roughly speaking) in proportion to the bulk of lung-tissue lying between every part of each half of its surface and the main bronchus of the corresponding lung. The movements of the thorax cause not only expansion of the lungs, but also gliding of the pulmonary over the parietal pleura.

Every structure within the thorax, save the lungs, is subjected to a varying negative pressure by the elasticity of these organs. During inspiration this pressure is of course most marked. It is this which causes the diaphragm to arch up and the intercostal spaces to curve inward. It is this which determines the position and shape of fluid masses in the pleural cavities, and the displacements of viscera in pneumo-thorax.

Fluid in the Pleural Cavities, as is beautifully demonstrated by Garland in his paper on "Pneumono-dynamics," does not assume a "hydrostatic," but a "hydrodynamic," level. That is: because of the negative pressure of the lungs, the surface of the fluid is made to take a peculiar shape. It is not level, as it would be under the influence of gravity alone, but is drawn up so as to apply itself to the surface of the contracting lung. The line of flatness at the fluid-level is not straight, but curved. Moreover, the same negative pressure may prevent any great change in the fluid-level with change of posture. Garland illustrates these facts by means of simple and ingenious apparatus. He also calls attention to the fact that active compression by fluid of an elastic body like the lung is impossible, until the elasticity of that body is overcome. The fluid allows the lung to contract, does not press upon it until the chest is very full and the contractile power of the lung exhausted. Of course, as far as the effect upon the blood circulation and air movement within the lung is concerned, it does not make any difference whether the elastic tissue contracts, or the fluid compresses it; but it is very important to remember that, until this negative pressure ceases, the intercostal spaces will continue to be depressed, and the abdominal viscera will not be much displaced. Not so with the heart, since the elasticity of the lung on the sound side produces a negative pressure which causes its displacement toward that side when fluid is present in too small quantity to do so.[1]

All this is so obvious, when once stated, that it is needless to discuss it. The position assumed by the lung when actively compressed by fluid, or when pneumothorax allows it to contract, is usually entirely wrongly shown in diagrams, and is misunderstood by many writers. It is a common idea that the lung under these circumstances contracts toward its bronchus. This is not so. Held by the broad ligament, it contracts so that (unless there are old, firm adhesions) it lies along the spinal column in the vertebral groove. That this is the case can sometimes be demonstrated during life by pretty hard percussion, which will show dulness near the spinal column from about the spine of the scapula to the bottom of the chest, while flatness will be found everywhere else in cases where there is a great amount of fluid. In some cases in the same region the subcrepitant râle is heard. Post mortem the lung is usually found in this situation if the contraction or compression is sufficiently marked. If not, the position of the lung is partly determined by its elasticity, partly by its attachments, and partly by its power of floating because of the air contained in it. These various factors modify the physical signs.

Physical Signs.—I shall speak only of a few physical signs, and the probable mode of their production, since this paper is already very long. It is necessary to define some terms for the sake of clearness. On percussion, we find over different parts of the normal chest and abdomen, in different cases, pulmonary, tympanitic, or vesicular resonance, with certain modifications thereof, as tubular resonance, flatness, bony resonance, the cracked-pot sound, and certain combinations or modifications of the above, as vesiculo-tympanitic resonance, and dulness. Pulmonary and tympanitic resonance, with their modifications, and in the cracked-pot sound, flatness, and bony resonance, have each one distinguishing feature, namely, quality.

Dulness has none. It is merely some type of resonance modified more or less, usually by an increase of the flat tone which is always audible to trained ears in any

[1] Although Garland's demonstrations and explanations of the behavior of fluid in the pleural cavities are excellent, it must be remembered that a human lung differs in its attachments from a dog's, and the lung, therefore, must contract in a somewhat different manner.

percussion-note. No absolutely pure percussion-note save flatness exists. By flatness is meant what is sometimes called "absolute dulness," namely, the note obtained on percussion over the thick muscles of the thigh, or over a large fluid accumulation in the chest or abdomen, etc. This note is high-pitched, short, and of little intensity, and of a quality called flat. It is impossible to describe sound quality. When anyone can describe the taste of potatoes, possibly he can describe the quality of a sound. Neither of these things has yet been successfully reduced to writing. I believe, as has been said, a flat, short, high-pitched tone always accompanies any other type of percussion-sound. It is produced by the pleximeter and the solid tissues which cover the organs producing the more pronounced sound. Dulness is produced when this flat note becomes more, while the pulmonary or other note becomes less, intense. It is difficult to distinguish, in all cases, a rise in pitch from a change in quality. Where the lungs, for example, cover with a thin wedge-shaped edge the liver, the pulmonary note certainly rises in pitch. It is also duller, and to the writer this dulness seems due to a change in quality produced by diminished pulmonary, and increased flat, tone.

Flatness is a tone possessing an absolute quality, but not an absolute pitch. In pulmonary and tympanitic or any other resonance the quality is not pure.

In percussion it is well known that the direction of the blow changes greatly the resulting note. It is not, however, usually appreciated how great a range of notes may thus be obtained. In the intra-clavicular region of healthy adults the writer has frequently obtained notes running through one-fifth and even one-sixth of a musical scale, simply by directing the blow toward the trachea, then gradually more and more backward, then toward the external wall of the chest; the pleximeter always being held in the same position.[1]

Pulmonary or vesicular resonance is heard over a large part of the normal thorax. It is a tone whose predominating quality is produced by the cavity of the chest with the contained sponge-like lung. It is produced neither by the air-filled lung alone nor by chest cavity alone. The former produces a much lower-pitched and feebler, the latter an amphoric or tympanitic, note. The spongy lung dampens the thoracic tone, and the thoracic cavity, with, to a certain extent, its walls, resound with the lung, and together they produce what we call pulmonary resonance. The pitch of this resonance varies with the elasticity of the chest-wall and with the size of the thoracic cavity. A large chest usually gives a deep tone. A smaller, elastic one does the same. The note of a large chest is, I think, of greater volume or intensity than that of a smaller, elastic one.

Bony resonance is heard over the sternum, and in some cases, especially in old people, over a large part of the chest. It is interesting to note, in connection with the statement that dulness is usually a mixed tone, that the heart produces on gentle percussion a dull note where it lies under the sternum, but on stronger percussion, when the force of the blow causes the whole bone to resound, it obscures the flat heart-sound.

Tympanitic resonance is produced by hollow viscera, by consolidated and compressed (or contracted) lung, and by cavities in the lung.[2]

In all cases save those in which this note is heard over solidified, contracted, or compressed lung, its mode of production is sufficiently clear. In the latter cases, so far as I know, the quality and pitch of tone is always the same as that produced by percussing the trachea, if the upper part of the chest gives it out; if the lower, either this note or that of the abdominal viscera. It has been suggested that the contracted lung over fluid is in a physical state resembling hollow viscera, and produces a note more by the vibration of its contained air than the mixed tone of its air and its stretched pulmonary connective tissue, etc. Possibly this is so. As far as I have observed, however, it has seemed to me that the note is identical with that of the trachea and large bronchi, or abdominal viscera. In children, the relatively large size of the bronchi and trachea compared to the vesicular part of the lung, together with the very elastic chest-walls, makes the occurrence of this note, under the conditions we are considering, very common.

The cracked-pot sound is heard frequently beneath the clavicles of healthy children, as well as over cavities, consolidated and compressed or contracted lung, and in pneumothorax. The fact that it is heard so often over normal lungs in the infra-clavicular region in children throws, I think, much light upon the mode of its production. The walls of children's chests are elastic, the bronchi and trachea relatively of large size. The sound is best heard when, the mouth being opened, a rather heavy blow is struck, the plexor being allowed to remain upon the pleximeter. This annuls, as far as may be, all thoracic vibration. The blow is really a pushing one, which is calculated to compress the lung and drive a good deal of air into and through the large tubes, larynx, and mouth; this causes the sound. It may be fairly imitated if, when a patient whispers, the chest be suddenly squeezed just as a word is being uttered, both hands of the observer having been placed over the lower ribs. In the case of consolidated lung, or lung over fluid, is it not probable that precisely the proper degree of elasticity may, in some cases, obtain to admit of drawing air out in a similar way? In pneumothorax also, with free opening into a large bronchus, and in some cases of cavity, this explanation seems reasonable.

Precautions to be Observed in Percussion.—Probably many good auscultators exist for one good percussor. The note obtained in percussion is often very complex and difficult of analysis, the more difficult being of short duration. Pitch and quality are hard to separate. Moreover, percussion is usually badly taught by instructors. Not to weary you with the well-known advice regarding the mode of striking, etc., and the necessity of striking a quick blow, I wish to call attention once more to the great need of comparing the results of lighter and heavier blows, and also of examining the patient standing, and with the body naked when possible. I wish also to emphasize the value of the much-neglected study of the sensation conveyed to the finger used as the pleximeter. By this finger the sensation of resistance will often give a better idea of the level of fluid than the ear. In children's chests the sensation is of especial value, since their elastic chests often give notes from both sides. It is, moreover, remarkable what slight differences of pitch and quality may thus be appreciated.

Auscultatory Signs.—*Bronchial Breathing.* There is no doubt that this sound is produced by the air-currents in the larger bronchi and trachea, and possibly the larynx, nose, and mouth. It is heard normally over the trachea, the sternal notch, and upper part of sternum, and sometimes in the vertebral region near the scapular spines. It is also usually heard over consolidated and compressed or contracted lungs (especially, in the latter case, at or near the level of fluid, and sometimes below this level), over cavities, and over tumors (including aneurism) pressing upon the larger bronchi.

Its characters need no description, but, for reasons which will appear later, I wish to remind you that in it there is a pause between inspiration and expiration, and that expiration is prolonged and higher-pitched than inspiration. In cases of consolidation (as pneumonia), it seems probable that the solidified lung conveys sound better than the normal lung, and therefore is much like a stethoscope applied directly to a bronchus. The usual propagation of this sound at or near the level of fluid is

[1] Whether the alteration of quality from tubular to dull pulmonary corresponds to the pitch change or not, I cannot say.

[2] In one case, in a baby, I heard it over the whole left chest, which was distended with pus; and though the note sounded tympanitic, to the finger, used as a pleximeter, it felt flat. In this case the whole right chest gave out a very similar note.

explained, partly by the fact that here we have practically solid lung, and partly, probably, by the reflexion of the sound from the fluid. The absence of all sounds in most cases below the fluid-level is probably due to the fact that, though sound travels well through liquids like water or serum, or through solid tissues like compressed or solidified lung, it does not readily pass from solid to fluid media, or *vice versa*. Thick masses of fluid, therefore, usually prevent its transmission from the lung, while the contracted lung, at and near the fluid-level, forms a good sound-carrier.

It remains to speak of two conditions: where there is absent breathing over solidified lung, and where there is bronchial breathing below the level of fluid.

Absence of breathing over solidified lung may be found where the whole or a part of a lung is involved. In the former case it is possible that practically no air enters or leaves the larger tubes. In the latter, possibly a plugged bronchus may account for the phenomenon; possibly at times the consolidation is of such character as to transmit sound badly, resembling more or less in physical characters œdematous exudate. Possibly in some cases the diminished movement of the affected chest may explain it.

Bronchial breathing is often heard below the fluid-level in adults with a very full chest, and in children. In the latter the relatively large size of the bronchi seems to explain the fact. In the former, with over-full chests, the fluid and compressed lung together are practically like consolidated lungs, forming a good medium for sound transmission. The fluid pressing upon the lung-tissue is like the stethoscope pressing upon the chest-wall. The bronchial sounds go through it in the same way. Vocal resonance is carried in a similar manner, but vocal fremitus with its larger waves is checked by the fluid (probably because of the inertia of the latter).

The vesicular murmur, or normal pulmonary respiration, has been the subject of much dispute. As this paper is already too long, I shall only speak of a few points in regard to it. First, unlike bronchial breathing, its expiratory sound is lower pitched than the inspiratory, and there is scarcely any pause between the two. Second, both in pitch and quantity, both sounds differ from the bronchial type. Third, it is absent when from any reason air does not move in the vesicles, and the latter, therefore, do not dilate or contract. Finally, the murmur is no more distinct in places where there is most movement of the pulmonary over the costal pleura (*i.e.*, over the anterior lower parts of the chest). The sound can, therefore, not be due to pleural movements.

Now, this murmur might conceivably be the bronchial note modified in its transmission through the lung tissue; but if so, the modification is certainly peculiar, since it fills in the pause between two sounds, lowers the pitch of one relatively to the other, alters the absolute pitch of both, and utterly changes the quality of both. Moreover, if the sound be simply transmitted and altered, the plugging of a bronchus or other obstruction to vesicular movement should not abolish it. Recent experiments (which are rather crude), made upon lungs removed from the body, show that this murmur may be heard when all bronchial sounds are annulled, by introducing a loose cotton plug into the trachea.

The vesicular murmur must be produced in the lobules of the lung. The air-currents and the elastic tissue of the lung, or both, may cause it. That much motion of the air in the lobules, and therefore of the walls of the vesicles, occurs, cannot be doubted, if one considers the relative bulk of the vesicles to the bronchi, the position and direction of the latter, and the thoracic movements. The air rushes through narrow tubes into and from much larger passages. In so doing one would expect it to cause a sound. The expanding and contracting vesicular walls also, like any elastic substance alternately made more or less tense, must do the same. One or both of these must be the cause.

BLINDNESS FROM BABIES' SORE EYES.[1]

By SWAN M. BURNETT, M.D.,

PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY, UNIVERSITY OF GEORGETOWN; OPHTHALMIC AND AURAL SURGEON TO GARFIELD HOSPITAL; DIRECTOR OF THE EYE AND EAR CLINIC AT THE CENTRAL DISPENSARY, WASHINGTON, D. C.

THERE is a pretty general consensus of opinion, I take it, among the most advanced thinkers of the medical profession and of the public in general, that the chief office and crowning glory of medical science is, not so much the cure of disease already established, as its prevention. Someone of those born with a genius for figures and a tendency to run into calculation, has estimated how many years have been added to the average length of human life, within the last fifty years, by the discoveries in scientific medicine during that period. I don't now remember how many these years are, but it is a number quite large enough to be highly gratifying to the pride and humanitarian instincts of those engaged in the philanthropic work. There have also been some statistics set forth, I believe, by our gynecological brethren, showing how many years have been added to the average life of woman by the improvements in the operation of ovariotomy alone; and some very interesting and satisfactory statistics could undoubtedly be compiled, showing how many years of usefulness and comfort have been added to human life by the single operation of cataract extraction. But if the prevention and cure of disease in adults who have already performed a part of the allotted labors of life, and who would, as a rule, die and cease to be a burden to the community and themselves after, at most, a few months of illness, is a matter of great moment, and is to be considered the highest aim of the science to which we have devoted the best energies of our lives, of how much more importance is the endeavor to prevent those diseases of infancy which are not fatal, but which leave the subject of them helpless charges upon society, and with the terrible consciousness of lives blighted and bereft of that which makes them most endurable.

It is to one such affection that I wish to direct your earnest attention this evening. It is one in the consideration of which the ophthalmic surgeon and general practitioner can meet on common ground—or rather, one in which, in point of importance and responsibility, the ophthalmic is found to come last, and alas! too often, too late. I allude to the sore eyes of babies—*ophthalmia neonatorum*.

It is, of course, known to each of you, either from the experience of his own practice, or, more fortunately for him, from the practice of his neighbors, that ophthalmic neonatorum is sometimes followed by a destruction of one, or generally both eyes—a total loss of vision. But few of you are perhaps aware of the total number of eyes that are thus lost, from the fact that your observations are limited to your own fields of labor and those of neighboring practitioners. One or two, or at most probably half a dozen, cases of blindness from neglected ophthalmia neonatorum are probably as many as any general practitioner can call to mind; and there are physicians long in active practice who have informed me that they have never seen a single instance of the disease in many hundred deliveries. This has created an indifference to the whole subject, and a lassitude in taking hold of it, which is one of the greatest, if not the greatest, obstacle in the way of instituting proper measures for the prevention of the disease. We are apt to forget, in the self-satisfaction and security, born more largely of good fortune than of wisdom or skill, that eternal vigilance is the price we must pay not for political liberty alone, but for freedom from some of the direst calamities of life. It is not my wish to indulge in upbraidings, but I do wish to use as forcible language as I can command to insist upon the duty of the obstetrician in the premises, and to lay upon him the burden of the responsibility for the blasted lives of thousands of human beings, who are to-day groping their way through

[1] A paper read before the Medical Society of the District of Columbia, December 5, 1889.

the world shut out forever from the beneficent light of heaven. This may seem a strong indictment, but it is unfortunately one which can be proven true by facts and figures which are open to the investigation of all.

I shall not burden your attention or tax your memory with long tables of statistics which have been prepared, at much pains and with great accuracy, by a number of men in different parts of the world. The principal facts are set forth in the works of Fuchs, Magnus, Howe, and the Committee of the Ophthalmological Society of the United Kingdom, and to them I would refer those desiring to investigate into the truth of the statements made in this paper.

These statistics show that at least thirty per cent. of all the blindness in Europe and this country is caused by ophthalmia neonatorum. Bringing the matter, now, more directly home to ourselves, we find that the census of 1880 gave as the total number of blind in the United States as nearly fifty thousand. Of these there are, at least, fifteen thousand who have been blind from birth, and have been a constant care and expense. Many of them, it is true, are still in infancy and at an age when they would, under ordinary conditions of good vision, still be a charge to society; and there are a very few blind people who are in some way or other self-supporting. But as even more than an offset to these are those whose vision, while not lost, has been seriously impaired, and who are thereby greatly handicapped in the work of their lives, that have not been reported in the census under the heading "blind." Only those who are totally blind are enumerated in the census reports; even very serious defects of the senses are, I believe, not taken account of. It is then, I think, safe to say that there are fifteen thousand people in this country who are a charge upon the community as a result of blindness from ophthalmia neonatorum. Laying aside, for the moment, all considerations of humanity and sentiment, let us see what that means from a politico-economical point of view.

The minimum cost of sustenance of a single person in our best and most economically managed public institutions for the blind is about $132 a year. This makes, for the mere "keep" of these blind people, nearly $2,000,000 annually. But if these fifteen thousand people had not been blind, they would have been producers instead of consumers only, and their net contribution to the general fund can be taken as, at the least, one dollar a day, on an average. Adding this amount to the cost of their maintenance, we find that the total loss to the wealth of the United States each year is about $7,500,000. And this enormous loss to the commonwealth, gentlemen, is due to the ravages of a disease which is as surely preventable as small-pox! It is doubtful if all the epidemics of yellow fever and cholera in this country, for the last one hundred years, have cost the country as much in money as have the ravages of ophthalmia neonatorum in ten years. And yet the latter is a disease which is, in its incipiency, easily curable, and well-nigh absolutely preventable.

That the latter statement is not a chimerical fancy nor an optimistic exaggeration, is readily seen by a reference to the reports of the large lying-in hospitals, where the most methods of prevention have been in operation. Take, for example, the reports of the hospital at Leipsic, under the direction of Professor Credé, who was the first to use and bring permanently forward the method now well known by his name. In the years before his preventive measures were used blennorrhœa of the conjunctiva occurred in from seven to thirteen per cent. of all the children born in the hospital. After the method was put in operation there was practically an entire disappearance of the disease, only an occasional case showing itself as the result of some neglect on the part of an attendant. Reports from other hospitals in Berlin, Bonn, Dresden, Geissen, Marburg, and other cities, bear equally good testimony to the system, none of them reporting more than 0.5 per cent. of cases.

To many of you the plan of Credé is well known, but for the information of those who are not familiar with it, I will briefly state the principles of the method. Immediately after the umbilical cord is tied, the face and eyelids are wiped clean and dry. The lids are then opened, and a drop of a two per cent. solution of nitrate of silver is dropped in from a glass rod or by other proper means. The one application suffices, if properly made. This has been considered by some as needlessly heroic, and it is probably that in the large majority of cases a solution of even 0.5 per cent., or the use of another and milder antiseptic, or even proper cleansing with water, would prevent the outbreak of the disease; but for a sure and certain prophylaxis a two per cent. is needed. If the infecting bacteria have already invaded the conjunctiva and found a nidus, as is their habit, in the epithelium of the mucous membrane, an agent sufficiently strong to destroy the superficial layers of cells, and cause them to be thrown off, is essential to perfect safety. It has been found that, except in premature children, the reaction from this treatment is very slight, and no really evil results have as yet, I believe, been reported.

Hausmann's method of a thorough cleansing of the maternal passages with antiseptics, before and during delivery, is of course useful, but it cannot take the place of the prophylactic measures applied to the organ likely to be affected, or perhaps already holding the germs of the disease.

It being thus clearly demonstrated that there is what is practically a complete prophylaxis against a disease which adds at least thirty per cent. to the total number of our blind, it follows that, if the measures were rigidly enforced, this percentage of blindness would disappear, with its attendant misery and large expense to the community.

As a matter of fact, however, the advantages to be derived from these prophylactic measures are at present confined almost wholly to large lying-in hospitals, and the helpless infants whose fortune or misfortune it is to be born outside of these institutions have to take their chances, with little or no favor shown them on the part of the accoucheur. In practice among the better class of society, where cleanliness on the part of the mother is a matter of habit, of course the results from neglect of the preventive measures are not so marked; but even here the feeling of security on the part of the practitioner is perhaps as dangerous an element as the wilful negligence of it among the lower classes, where cleanliness is not the rule; for it is hardly necessary for me to state here that ophthalmia neonatorum is to be found where there can be no suspicion of gonorrhœa of the vagina. The greatest danger, of course, is to be feared in those cases of labor which have been attended by incompetent midwives, and by general practitioners who have, perhaps, never been made aware of their responsibility in such cases.

I find, on examination of the records of my clinic at the Central Dispensary, that serious defects in vision from ophthalmia neonatorum form about 1.5 per cent. of all the eye diseases treated, and in more than one-half of this number the blindness is practically absolute from sloughing of the cornea. In a single month there were brought to me three infants with total sloughing of both corneæ, from neglected purulent inflammation of the conjunctiva. And if you could have seen the look of anguish and reproach in the eyes of these mothers—two of them hardly more than children themselves—when told that their babies could never see again, the prophylaxis of ophthalmia neonatorum would not then have seemed to you a slight or trivial affair. "Nobody told me it was dangerous," they said. "They said it was only a cold in the eyes, and that if I put breast milk in them they would be all right."

If such cases came only from those delivered by ignorant midwives, we would have less to reflect upon ourselves as teachers and writers, but that consolation, I am sorry to say, is not allowed us. One-half or more of the

cases were attended by physicians who are licentiates of this Society. I am not aware to what extent the teachers of obstetrics, in our schools throughout the country, dwell upon the importance and necessity of the preventive and early and proper treatment of this affection, but I have had an examination made into the text-books on midwifery, from some of which the American student is expected to obtain the knowledge requisite for the proper care of the lying-in chamber. Dr. Gill, resident of the Emergency Hospital, who was kind enough to make this research for me, found that in more than thirty standard works on obstetrics in English, in the Library of the Army Medical Museum, there were only four which considered the preventive measures of which we have spoken. These were the "Encyclopædia of Obstetrics and Gynecology," and the treatises of Barnes, Lusk, and Cazeaux and Tarnier. In only six others, and they were mostly old works, was there any consideration given to the treatment of the disease when it had been once established. It may possibly be said that the affection falls more properly under the head of pædiatrics, and that we should look for an account of the disease and its treatment in the works on diseases of children. Even if that were true as regards the disease already in action, it does not absolve the obstetrical writer and teacher from his duty in regard to prevention; and, besides, the care of the child for the first few days after birth, and during the period when the disease is likely to be set up, belongs to the obstetrician as pertinently as does that of the mother herself.

It is obvious, then, that our first duty is to arouse our teachers and writers on obstetrics to the necessity of instructing their pupils as to the proper care of the eyes of the child from the very instant of its birth. If they are not willing to adopt what they may consider the heroic method of Credé, let them at least be instructed to wash the eyes with some antiseptic solution, and examine into their condition at each visit for at least a week. This would, at any rate, keep the attention directed to the eyes, and allow for the discovery of the first manifestation of the disease, and in time—and at the only time—for its most successful treatment. This is the very least the most timid should be expected to do. The thoroughly conscientious man would, of course, adopt the sure method of Credé at once.

But there yet remains a large percentage of cases not attended by physicians of any kind, and among a class of people where the conditions for the development of the disease are most favorable.

These people cannot be reached through our teachers or our text-books, and yet it is highly important that in some way they should be informed of their danger. Various methods of accomplishing this have been suggested.

The Ophthalmological Society of the United Kingdom took the matter in hand, and in 1884 its committee, composed of the leading men in the Society, made a report of a series of resolutions which I here copy, as embodying a method some modification of which I deem adapted to the necessities of the case in this country:

"1. That purulent ophthalmia of new-born infants being the cause of a vast amount of blindness, mainly because of the ignorance of the public regarding its dangerous character, and the consequent neglect to apply for timely medical aid, it is desirable to instruct those in charge of new-born children by a card, in substance as follows:

"*Instructions Regarding New-born Infants.*—If the child's eyelids become red and swollen, or begin to run matter within a few days after birth, it is to be taken without a day's delay to a doctor. The disease is very dangerous, and, if not at once treated, may destroy the sight of both eyes."

Then follow some suggestions as to the method of distribution of these cards by means of the Poor law and Birth registration organizations throughout the United Kingdom.

"2. That the advocacy and aid of the medical press be solicited in drawing general attention, and especially that of the authors of text-books on midwifery, of the lecturers on the same subjects for students and midwives, and of the various institutions which train, and the charitable institutions which employ, midwives, to this important subject."

The subject was again brought forward for discussion at the last meeting of the British Medical Association at Leeds, by a paper of Dr. Karl Grossmann, of Liverpool. It was the unanimous opinion of all those who took part in the discussion that it was a matter for governmental interference, and there is no doubt in my own mind that the governing authorities should take the subject in hand, and protect society as far as possible from an infliction which is nothing short of a national calamity. But even if the subject is not likely to be made a matter of legislation for some time, the governing powers can at least lend the aid of their machinery for the distribution of such information as shall put those about to become mothers, and those having the immediate care of the new-born, on their guard.

In our own city, I think the Health Office could render great aid in this matter by causing the distribution of cards like the following, which is a copy of that furnished by the Eye Infirmary at Sheffield:

HEALTH DEPARTMENT, DISTRICT OF COLUMBIA.

IMPORTANT NOTICE.

If a baby's eyes run with matter and look red a few days after birth, take it AT ONCE to a doctor. DELAY is DANGEROUS, and one or both eyes may be destroyed if not TREATED IMMEDIATELY.

The cards should be given to the physicians of the poor for general distribution in their respective districts, with such instructions and explanations as shall lead to a full comprehension of the danger. They should also be left for distribution at the various dispensaries, and at whatever other public institutions those for whose benefit they are intended are to be found.

The cost of printing such cards would be trifling, and if there are no public funds from which the cost could be paid, I think there is no doubt but that it would be forthcoming from private charity. This, it seems to me, is the very least that we can or should do.

A few words in regard to the proper management of the disease when once it is set up may not be out of place here. The first and most important thing is cleanliness. The eyes should under no circumstances be bandaged. Free exit should be given to the discharge, and the matter should be wiped off with a soft sponge or, better still, absorbent cotton, dipped in an antiseptic solution, as fast as it is formed. This, of course, necessitates constant and unremitting attendance. The eyelids should be opened as wide as possible and the matter washed off the conjunctiva of the everted lids with a stream of antiseptic, or at least aseptic, liquid—such as a solution of boric acid, or of sublimate 1 to 5,000—every fifteen minutes or every hour, according to the quantity of the discharge; and three times a day the conjunctiva, after it has been wiped dry, should be washed over with a one to two per cent. solution of nitrate of silver by means of a camel's-hair brush. As the swelling and discharge diminish, the interval between these applications is to be lengthened. All cloths, sponges, or cotton used in connection with the eyes should be boiled or otherwise disinfected, or, better still, burned; for not the least of the dangers of the disease is the liability to infection of the eyes of the attendants. And for this reason, also, the hands of those treating or examining such eyes should be carefully cleansed and disinfected immediately afterward.

American Society of Microscopists.—The next meeting of the American Society of Microscopists will be held at Louisville, Ky., beginning August 12, 1890, and continuing four days.

GENERAL HISTORY OF THE EPIDEMIC OF INFLUENZA.[1]

By A. JACOBI, M.D.,

NEW YORK.

MR. PRESIDENT: The time at our disposal having been divided by you among several fellows, I shall confine my remarks to but two subjects connected with the epidemic influenza of the last month, viz., its character when studied in infants and children, and the treatment of the most dangerous features of the very worst cases.

Infants and children, like very old people, were rather more exempt than those between the fifteenth or perhaps twentieth, and the fortieth year. It was not always so, for the history of some of the epidemics emphasizes the fact that in them advanced age suffered considerably. I am not prepared to suggest a reason for the comparative immunity of the young; perhaps it is that they have been less exposed to the inclemency or variations of the weather. The temperatures of the little patients were often but moderate, and quite the reverse of what we are accustomed to observe in all feverish diseases at that age. Still, our observations are subject to mistakes because of the efficacy of our modern antipyretics, which have become too ready instruments in the hands of the anxious practitioner. This circumstance may also account for the absence of the abrupt defervescence and critical symptoms in general, so common in the influenza of the adult.

The usual symptoms of infectious diseases, such as lassitude, muscular pain, sleeplessness, delirium, dry heat or perspiration, suddenness of the attack, or incubation of seldom amounting to, or more than, one or two days, and anorexia, are met with in influenza of all ages. The local symptoms of the mucous membranes are very extensive. In a common catarrh they are limited to a few; in pertussis they are still more circumscribed locally; in influenza the respiratory organs, from the nose and frontal cavities to the bonchioles; the digestive, from the oral cavity to the rectum, are apt to suffer. According to the more exposed or stricken locality, the symptoms may vary in individual cases; there may be chill or heat, vomiting, constipation, or diarrhœa, presence or absence of cough, and dry or secreting Schneiderian membrane.

Nasal discharges were seldom copious, still more rarely tinged with blood. Hoarseness and croupy cough were but rare. Intense laryngitis, such as required tracheotomy in a few of the Russian cases which have been reported, I have not seen. Bronchitis with rhonchi of every description was frequent; the paucity of visible expectoration is explained by the difficulty young children have in bringing up the discharged material which is swallowed. The bronchial catarrh was very general, and extended over every region of the lung, sometimes with apparently but little suffering. Still I have seen, in children of six years and upward, considerable dyspnœa with slight cyanosis. The frequency of extensive bronchitis furnishes the explanation of how it happened that the pneumonias observed during influenza were genuine croupous, in less numbers than usual. I estimate that, of a hundred pneumonias of all periods of childhood, one-third are of the genuine lobar variety; during the three or four weeks, however, in which I saw influenza-pneumonia, I have not seen a single uncomplicated case of that variety. Long after the rational symptoms pointed to the presence of pneumonia it was impossible to discover bronchial respiration, or even bronchophony, which is detected so much more readily; dulness developed very slowly, but was mostly quite extensive; older children would now and then expectorate small quantities of blood, sometimes of a more or less bright color, or mixed with thin mucus, but never rusty. Extensive dulness was often over the upper lobe, particularly when there had been much cough—a good illustration of Dr. Melltzer's theory of the origin of pneumonia detailed in the MEDICAL RECORD. Sometimes the dulness was pleural; in a few cases the fluid removed by explorative puncture was serous, but rather turbid; finally, however, it was absorbed. In one case only it was so turbid, containing pus-cells in small quantities, that aspiration was resorted to. From the left pleural cavity of that child, a girl of less than two years, a few ounces were removed, with convalescence following.

Infants under a year did not suffer much from the respiratory symptoms of influenza. It is only from the second year that these are liable to appear in large numbers; before that the locality of least resistance is the alimentary tract. Pharyngitis and amygdalitis were sometimes absent in the beginning, or but little marked, even in cases of otherwise intense suffering and great prostration. Indeed, the injected throats, so prevalent during an epidemic of scarlatina or diphtheria, were not universal in uncomplicated influenza. Follicular amygdalitis, I have seen but once in such a case, without being able to point to an actual connection between the two. When the whole oral cavity suffered, it was generally the tongue that began to be affected. The edges became red, the papillæ elevated, even the gums slightly congested and of looser texture. In accordance with the mild affection of the throat, swallowing was rather easy, with the exception of those cases in which there was much rhinitis and consecutive conjunctivitis. The latter, I may here be permitted to state, I never met as the first symptom; that must have happened to the author who placed the location of invasion in that organ. Otitis media I have met with three times, in one case on both sides. The four tympana ruptured spontaneously, and I am told that all are doing well. Vomiting in the beginning was quite frequent, loss of appetite the rule, diarrhœa not uncommon; rectal catarrh with tenesmus, I saw once only.

The scarlatinous eruption mentioned by many I met with but twice; once over the chest only, in a child of two years, with but a slight elevation of temperature; once over the whole surface, with a temperature of 104° and more. I took it for the general erythema liable to appear in predisposed children during any fever. Facial herpes, mostly on the lips, I met several times; urticaria, though it be common enough at that age, not a single time. In the case of serious broncho-pneumonia in a girl of five years, I was told that there had been urticaria ten days previously. It may be that there was a peculiar tendency to exudation, giving rise to urticaria first, and pneumonia afterward, depending on either the structure of the blood-vessels, or on vasomotor influence. Beaumetz's theory, that the presence of eruptions is a characteristic symptom distinguishing this year's influenza from the common form of catarrhal fever, I cannot share. The nervous symptoms were those common to all feverish diseases. Vomiting was probably due to gastric catarrh, and not to cerebral irritation. Headache was frequent, almost the rule; diagnosticable in infants by the vertical contractions of the frontal muscles, and the dazed appearance of the patient; it was a frequent complaint in children of from six to twelve years. A convulsion occurred in a child of three years whom I saw but once, ten days afterward, for pleuro-broncho-pneumonia; very severe intercostal and abdominal neuralgia in a boy of six, with pleurisy of the right side; rigid contraction of the muscles of the neck occurred in several infants, and lasted from one to three days. Temporary delirium was present in a few children with high fever. Paralysis, mentioned by Da Costa, I have not seen. Pain in the extremities was frequent; older children would complain like adults; infants moan or scream, and object to being moved. A tall girl of five, who was reported to be a chronic sufferer from growing pain, had excessive pain about the knee and ankle joints. Passive motions did not add much to her suffering, but the slightest pressure on the epiphyses provoked intense screaming spells. Evi-

[1] Read before the New York Academy of Medicine, February 6, 1890.

dently her chronic epiphysitis had met with an exacerbation during her influenza. One girl of three years I was called to see for articular rheumatism; the synovial membranes and cavity of the sensitive knee were intact, but the intense pain of the epiphyses of the two femora and tibiæ rendered the diagnosis easy. Cold applications and immobilization proved beneficial in a brief time.

The weekly reports of the Health Department furnish the average number (in seasons of average severity) of cases of scarlatina and diphtheria. The comparative absence, however, of measles, and also pertussis, is striking. The two latter are frequently contemporaneous, or precede each other. Their absence during the epidemic of influenza may be accidental, but future research will have to teach us whether it is more than a mere casualty. Vienna journals report the diminution of measles *pari passu* with the invasion of influenza.

Relapses of influenza were certainly not so frequent and marked in the young as in the adult, perhaps for several reasons. The disease was often milder than in advanced age, with a tendency to last longer and terminate in more gradual recovery. But the main reason for relapses was probably wanting, that is, errors of diet committed by the adult, and premature exertion and exposure.

Individual prevention consists in protection against exposure. The skin can be fortified against the results of sudden changes in the temperature by the habitual daily use of cold washing, sponging, or bathing. Catarrhal affections can be avoided by equable temperature of the room and warm clothing. It is true, however, that these measures are more serviceable in common catarrh than effective against the epidemic invasion of influenza. Still, the increased vigor of the superficial integument renders the internal integument, the mucous membrane, more enduring.

If influenza were a miasmatic disease only, no caution would protect. Among those who claim influenza to be a miasmatic disease only, is August Hirsch, than whom there is no greater authority on the history and geography of maladies. His main reason for believing the disease to be miasmatic is its brief duration. But the number of those who take it to be more or less contagious is by no means small. Of the latest authors I mention only Guiteras (MEDICAL RECORD, January 25th), Nothnagel, and Fürbringer, who compares the contagious nature of influenza with that of typhoid fever.

There can be no doubt as to the miasmatic origin of influenza in many well-authenticated instances. Thomas Watson, in his "Lectures on the Principles and Practice of Physic," London, 1871, vol. ii., p. 46, refers to the case of the frigate Stag. After having arrived near the coast of Devonshire, during a head wind, on April 3, 1833, she had forty sick within half an hour, sixty more in two more hours, and one hundred and sixty on the following day. But the dissemination of miasmatic germs has its limits. We can hardly suppose that they can be carried thousands of miles through air-currents; and the assumption of a proliferation in the air itself is contrary to everything we know of the biology and increase of disease-germs. Thus, even when we assume that some stray germs may be saved from destruction in their various travels, we cannot believe that all at once they should so multiply as to infect hundreds and thousands in almost an incredibly short time, particularly in the winter and on a snow-bound coast.

To explain this rapid multiplication we have to fall back on the aid of either soil or the human body. But influenza is found on every soil, normal or frozen, dry or moist, and not every soil suits every germ in the same manner. Thus, it follows that the human body and communication between human beings furnish a readier explanation for the rapid spreading of the disease. E. A. Parkes, in J. Russell Reynolds' "System of Medicine," vol. i., refers to Haygarth and Falconer in the last century, who traced a number of cases to direct contact. During the height of an epidemic in large cities it is impossible to prove that, but in the beginning of an epidemic, and in the scantily populated districts of the country, such proof can be more easily furnished. The short duration of incubation is no reason for denying contagion, for scarlatina yields numberless examples of the same experience. Bäumler[1] relates that the first two cases in the surgical clinic of Freiburg were due to a lady lately arrived from Paris. In the hospital the patients in opposite beds caught the disease first. Thus, it appears that while influenza is a miasmatic disease, it is also intensely contagious, and with very short incubation. The fact that in a house full of influenza patients one or more may escape, does not militate against the contagious nature of the disease, for the same observation is frequently made during the epidemics of scarlatina, measles, and diphtheria.

Therefore, in the interest of prevention, the attempt at isolation of the sick, or the well, is justifiable, though the volatile nature of the pathogenous influence is so marked as to render quarantine mostly futile. The immunity, often experienced, of monasteries and penitentiaries justifies the non-admission of influenza patients to public hospitals as far as possible. Thus it was that I advised against their reception in the Mount Sinai Hospital. It is true, though, that serious sequelæ or complications cannot possibly be excluded, nor the invasion completely avoided. The question whether the schools ought to be closed during an epidemic is a very serious one; perhaps the consideration that children do not suffer to the same degree with adults militates against the enforcement of such a measure. In Vienna, a few weeks ago, the Christmas vacations, just entered upon at the outbreak of the epidemic, were lengthened. If the schools cannot be entirely closed, care ought to be taken that they be aired more carefully than ever, thoroughly heated through the night, and an equable temperature, measured more by the thermometer than by the individual pleasure, wants, or sensations of the teacher, kept up all day.

Though influenza be a self limited disease, it must be treated. The discomfort it carries with it, the prostration it produces, the sequelæ which render its invasion a possible or probable danger, require relief. Statistics prove nothing when it is stated (as for instance in Berlin) that no death has occurred of influenza. Statistics prove a great deal when we remember that a few weeks ago our death-rate was doubled. There is no better instance to prove that not the malady but the sick must be treated. Treatment will not shorten the disease, but it may save strength, and facilitate and shorten convalescence. The patient must keep in bed during the illness and part of the convalescence. Whoever does not, risks a relapse. Eyes and brain are rested by excluding bright light and noise. Muscular pain and fever can be soothed by diaphoretics—acetate of ammonium, aconite; cough by opiates; intestinal stagnation and gastric discomfort by a single purgative dose of calomel administered at once; very copious secretion by belladonna. Beverages must not be iced; food fluid.

All the known old and modern antipyretics have been used. Quinine appeared to me to have a better action during convalescence, in a few daily doses of from one to three grains, than during the height of the fever. There are cases, however, in which a larger dose has the effect, often experienced, of prolonging the action of any of the modern phenol preparations. A very large dose, say of thirty grains, would combat supra-orbital neuralgia, where smaller doses, or other sedatives had failed. In a series of influenza cases, from ten to twenty grains of quinine were taken in the forenoon, a single dose of phenacetin, of from twelve to twenty-five grains, in the afternoon, and a Dover powder at night, with pleasant effect. There is not one of the modern remedies but whose virtues have been tried and extolled.

[1] Bäumler, in Münch. Med. Woch., 1890, No. 2.

Acetanilid ought to be preferred among the poor, because of its low price, antipyrin mainly where great solubility is required for the purpose of its administration in rectal and subcutaneous injections. Phenacetin is preferable to either, because of its less uncomfortable effect on brain, heart, and skin.

Gastric irritation behaves best under resorcin; gastro-intestinal disorders have been treated with salol, salicylates, and salicin. The first is not always well tolerated; salicylate of sodium is apt to add to intestinal irritation; salicin is perhaps the most effective and least irritant of all. The dose for an adult is from five to fifteen grains every two or four hours; those of T. I. Maclagan (*Lancet*, January 11th) are larger. He gives, for three or six hours, twenty or forty grains hourly, after that time every two hours, and later on in longer intervals. By this treatment he claims to have obtained the beginning of convalescence within from twelve to twenty-four hours. I find it difficult, however, to believe that anything like abortion can take place, in response to internal medication, in a disease the invasion of which is sudden, incubation exceedingly brief, and defervescence to be expected after two or four days.

Infants and children require all of these remedies in proportionately large doses.

Mr. President, I am aware that I shall be followed by those who have ample experience and vast knowledge of the subject under discussion, and that my remarks must be brief. I shall therefore add a few fragments only to say that, while the treatment of the acute attack may permit of laxity and leeway, that of some of the complications and sequelæ taxes the heart and brain of the physician to the utmost. To this very hour I am under the ban of the impression made by men, women, and children, perishing by the dozen of pneumonia, broncho-pneumonia, and pleuro-broncho-pneumonia. I need not tell my audience that never have we seen so many cases of pulmonary disease of a peculiar type and fatal character in a few weeks. The subject will be discussed by one of the gentlemen who are to speak to-night; thus I shall refrain from everything in this connection, with the exception of a few remarks on the therapeutics of these severe cases. I venture to make them, though perhaps they be but a repetition of what everyone here is fully acquainted with.

The great danger is prostration, exhaustion, heart failure, particularly in very old age, after previous illness, in phthisis, chronic pneumonia, emphysema, kyphosis, cachexia, alcoholism, nephritis. Wherever vomiting is severe, feeding by mouth is an impossibility, and absolute abstinence adds to the general exhaustion. Thus rectal injections must take the place of stomach feeding. May it not be forgotten by my younger colleagues that, besides alcohol much diluted and peptones in solution, nothing is better absorbed by the rectum and colon (the latter to be reached in the adult by a long tube attached to the nozzle of the fountain syringe) than egg stirred in fairly large quantities of fluid; that the quantity to be injected may be as large as from half a pint to a pint if it be made to reach the colon; and that starch-water is preferable to water, inasmuch as starch is transformed into dextrin in the larger intestines.

When there is excessive perspiration, fair quantities of fluid must be injected at regular intervals to repair the loss.

Severe vomiting is best alleviated by morphia, internally, if possible, otherwise subcutaneously, or to the oral cavity in such a manner that a few drops of Magendie's solution are poured into the hand or a spoon, undiluted, and sucked down along the mucous membrane, which absorbs it very readily.

Very high temperature prevents absorption from the stomach. The readiest methods to reduce it, particularly when the stomach rejects remedies, is the subcutaneous use of antipyretics, whenever the rectum is either wanted for feeding purposes, or is not in a fit condition to retain and absorb. Antipyrin may be so used in five parts of water, the carbamide of quinia in the same proportion.

Suffocation with cyanosis has been relieved, and time gained, by the inhalation of oxygen, a few minutes in succession, every ten or fifteen minutes. The current of the gas must be introduced into the larger nostril, for the cyanotic patient, struggling for breath, does not use his mouth intelligently for breathing purposes. If the stomach be in good condition, Siberian musk, in doses of from five to ten grains, every half or whole hour, or two hours will act satisfactorily.

The worst cases of heart failure give your internal medicines no chance whatsoever. Subcutaneous cardiac stimulation is the only method promising any effect. Alcohol, pure or diluted, will act as an adjuvant only; indeed, it is not advisable to rely on one remedy where every lost minute may tell against the victim. Sulphate of spartein dissolves readily in water, and may be injected in doses of from half a grain to a grain every half-hour or hour, according to necessity; as it is readily eliminated, no cumulative effect need be feared. Salicylate of caffein and sodium (the benzoate is not quite so soluble) dissolves readily in the double quantity of water, so that a syringe holding half a drachm contains about a dozen grains of the double salt, equal to about six grains of caffein. Camphor dissolved in five parts of oil of sweet almonds, when slowly injected, is hardly ever painful, and much more pleasant than the solution in alcohol or ether. Convallamarin, in doses of from one hundredth to a twentieth of a grain, has also yielded satisfactory results in some instances. One-twentieth of a grain of strychnia adds to the effect of those enumerated above; the tact of the practitioner and close observation of the heart-beats, pulse, and general condition of the patient, who under such distressing and threatening circumstances must not be left to the care of a nurse, must decide which, and how many, of the remedies advised are to be employed, and how often, and at what intervals, they must be repeated. I know that not a few, who seemed hopeless, have been saved by strict personal attention.

CLINICAL NOTES ON THE COMPLICATIONS AND SEQUELÆ OF INFLUENZA.[1]

By F. P. KINNICUTT, M.D.,
NEW YORK.

THE marked predominance of symptoms which must be referred to a more or less profound disturbance of the nervous system, will be generally admitted as stamping the epidemic of influenza which has prevailed so extensively in our midst during the past several weeks. Such symptoms have characterized not only the onset and the febrile stage of the disease, but have been prominent in its complications and sequelæ.

Not a few cases which have fallen under my observation, and which must be regarded as true instances of infection, have been limited to such manifestations. They have consisted often of a slight feeling of dizziness at the onset, headache, occasionally nausea, more or less severe pain in the back and limbs, accompanied with a feeling of prostration and mental depression; the attack running its course in twenty-four or forty-eight hours, and with the preservation of a normal temperature throughout. The aggravated character of several of the above symptoms in more acute attacks need not be referred to. The rarer nervous phenomena which have been observed, both during the attack and as sequelæ, are of great interest. It is desirable to accumulate individual experience on this point. I shall therefore venture to record my personal observations.

Obstinate and acute neuralgias have occurred as sequelæ in many of my cases, of the trigeminal and sciatic nerves most frequently. I have seen two cases of periph-

[1] Remarks made before the New York Academy of Medicine February 6, 1890.

eral neuritis of moderate severity, but not accompanied by atrophic symptoms. The mental depression which has been so prominent and common a manifestation, need not be referred to further than to call attention to the suicidal impulse that has occasionally been associated with it. I have observed one case in which this was present. More or less active delirium during the attack, with very moderate elevation of temperature, has been present in several cases. A nurse in St. Luke's Hospital suffered from vivid hallucinations of sight for several days following the febrile stage. Obstinate and painful cramps in the calf muscles, manifesting themselves during convalescence, I have seen in several cases. An absence of the knee-jerk, mentioned by Da Costa in his recent paper, without reference to its association or not with a peripheral neuritis, has not come under my notice.

In one patient, a male adult, certain painful symptoms affecting the legs only, were believed to be due to a vaso-motor paresis. In two patients under my observation, a child five years of age and a woman of forty-eight, characteristic attacks of herpes zoster were developed during apparent convalescence.

In a single family I have had the opportunity of seeing, with Dr. Beattie, of this city, the following group of cases. Three children were attacked almost simultaneously with symptoms of influenza, fever, in the older children (four and six years) headache, and moderate tracheal catarrh. In all, the onset was accompanied by a general convulsion. In one case, only a single convulsion occurred; broncho-pneumonia was developed later, from which the patient has not yet recovered. In a second child, the influenzal attack was of slight intensity and short duration, but general convulsions occurred from time to time during the following week, and in the absence of all other symptoms. The third patient was an infant of eighteen months. Convulsions continued to occur until death, one week from the beginning of its illness, with an absence of other symptoms and physical signs than those of a moderate bronchitis. Such varied disturbances of the nervous system occur in few infectious diseases, and yet I believe they must justly be regarded as having their origin in a specific infection.

In conclusion, I desire to refer to certain features of the pneumonia, which has prevailed so extensively during the epidemic.

The two forms, broncho and primary lobar pneumonia, have occurred with nearly equal frequency in my experience, including both hospital and private cases. I have been impressed with the unusual severity of the former form in adults, and with the unusual amount of capillary hemorrhage, as indicated by the presence of a very considerable quantity of bright-red blood in the sputa, and with the frequency with which the latter form has involved both lungs. The diagnosis of primary lobar pneumonia was based upon the clinical course and physical signs of the disease, confirmed in a number of cases by autopsy (entire lobes in both lungs being in a state of uniform hepatization). Many cases which were undoubtedly examples of broncho-pneumonia, have presented the physical signs of an unusually extensive consolidation for this form.

In a case of pneumonia terminating fatally in St. Luke's Hospital, the autopsy disclosed a perfectly uniform and complete hepatization (red) of an entire lobe of one lung (the typical lesion of primary lobar pneumonia), and small scattered patches of collapsed pulmonary tissue and pneumonic consolidation (equally typical lesion of broncho-pneumonia) in the other. In other words, a primary lobar pneumonia apparently coexisted with a broncho-pneumonia in this case. Not a few cases of *apparent* pneumonia which have rapidly terminated fatally, I am inclined to believe, were really examples of simple massive congestion, associated with feeble hearts, either previously diseased or affected by the profound nervous depression accompanying the influenzal attack.

The above observations point to the exceptional severity of the pulmonary affections accompanying the present epidemic of influenza.

Through the kindness of Drs. Cutler and Bishop, of the house staff of St. Luke's Hospital, I am able to append the following summary of all cases of pneumonia treated in the wards during the epidemic: Lobar pneumonia, fifteen cases, seven deaths—both lungs involved in four cases. Broncho-pneumonia, nine cases, three deaths.

THE DERMATOSES OF INFLUENZA.[1]

By RAMON GUITERAS, M.D.,

NEW YORK.

I HAVE tried, in considering the subject before us this evening, to dwell especially upon some one branch of symptoms or complications, and for this reason have chosen some of the various cutaneous efflorescences which have occurred as concomitant with, or the result of, the disease in question, and to mention incidentally some accounts of complications and statistics which I have derived from interviews with various other physicians. In considering these various eruptions, the one which strikes us as by far the most important, especially from a diagnostic point of view, is the erythema which occurs in certain cases, and which so particularly marks them, that in considering this variety I shall classify it separately under the name of Influenza Erythematosa. This form of influenza so closely resembles scarlatina that a very careful diagnosis is often required to differentiate them; I will therefore consider some of those cases clinically, as in so doing we may get a better idea of them.

CASE I.—Clara S——, aged nineteen, was reported to the Board of Health as a case of scarlatina, and the Board was notified that the family desired her removal to the hospital. Dr. Dillingham, the diagnostician of the Board, was accordingly sent to investigate. Patient had been exposed to scarlatina some time before this; she complained of severe frontal headache, had frequent vomiting, and great prostration. Examination revealed girl suffering from an acute febrile attack, temperature 103° F., pulse 100, markedly prostrated, the conjunctivæ congested, and an erythematous blush present over face, chest, and upper extremities. On examining the tongue it was seen to be coated and enlarged, and reddened papillæ were seen on sides near tip. Considerable congestion of the fauces was also present. Dr. Dillingham said that, although he considered it a very suspicious case, it was nevertheless undoubtedly influenza, and advised isolation. On the following day the eruption had disappeared.

CASE II.—A similar one in a man aged thirty-six, who had been exposed to scarlatina. Isolation ordered. Eruption disappeared on following day.

CASE III.—Child aged six, temperature 104 F., marked delirium, followed in few hours by erythematous blush and symptoms above mentioned.

CASE IV.—Maid in private family, aged twenty-two. I had treated a case of scarlatina of a very mild type in the same family the week previous, in which the temperature did not go above 102° F. January 6th, was first called to see patient. She had been vomiting and suffering great gastric distress, severe frontal headache, marked prostration, etc. Erythema of face, chest, and upper extremities. Temperature, 103° F., pulse, 108. Angina, furred tongue, and enlarged papillæ on sides near tip. Eruption faded in twelve hours.

Dr. Lynde, of the New York Foundling Asylum, reported six similar cases, in all of which the eruption disappeared in twelve hours. These cases all occurred in adult females, ranging in age from twenty to thirty years. Several other physicians in this city have noticed similar eruptions.

Dr. Simpson, of Plainfield, N. J., reported such a form of the epidemic as being quite prevalent there among

[1] Read at the Meeting of the New York Academy of Medicine, February 6, 1890.

children. According to the cases noticed by observers in this city, however, it would seem that it is more prevalent among adults, and that too in adult females. The resemblance between this erythema and scarlatina is at first glance a striking one, but a careful examination will reveal many points of difference, *e.g.*:

Erythema.	Scarlatina.
Temperature not as high.	
Pulse not as rapid.	
Eruption only over face, chest, and upper extremities, not punctate, but a general pinkish blush.	Eruption over face, chest, and both extremities, begins in a fine, punctate manner, tends to coalesce, and is of a bright scarlet hue.
Angina not as marked.	
Tongue has thick white coating, with enlarged papillæ on sides near tip.	Tongue not as thickly coated, but more markedly strawberry.
Skin moist.	Skin hot and dry.

Herpes labialis has been observed in several cases, occurring principally in the catarrhal form of the disease, appearing generally on the second day and lasting for three or four days.

Miliaria has also been observed occasionally during the epidemic. In one case, where it was quite marked over neck and chest, patient was suffering from the gastric form of the disease. It generally occurs in the papular form, and is only of a few hours' duration.

A peculiar papular eruption occurring discretely over neck, arms, and chest, has been observed by Dr. Byron in several cases of influenza, among the Italians seen at the New York Dispensary. The papule is quite large with an irregular base, and of a bright red color, closely resembling an erythema multiforme. It appeared generally on the second day, and disappeared in two or three days.

Urticaria has also been reported as occurring in some cases of the gastric type of the disease, coming on at onset and lasting for about twenty-four hours.

Various other eruptions have also been mentioned as occurring during the epidemic, but not in sufficient numbers to warrant their mention in connection with the disease. For instance, one observer mentioned a case in which the rheumatic pains were intense, and which was accompanied by a furunculosis scattered over the entire body.

Again, a woman, aged forty, who had been suffering from influenza for some three weeks or more, accompanied by severe rheumatic pains, was suddenly attacked by an eruption, eczematous in character, scattered in patches over body and extremities, which is still present.

These two latter cases I simply mention as occurring coincidently during the epidemic, and attach no further importance to them.

After reviewing the various other groups of eruptions above mentioned, most of which are erythematous in character, it seems to be an open question whether they are dependent upon the disease directly, or the gastric complications accompanying it.

Acute Hyperæmia of Tongue.—Dr. Burke reported seven cases of sore tongue—in which cases the tongue was enlarged, reddened, hard and tender, so that the pressure of the teeth against it was quite painful. There was also a feeling that the tongue was too large for the mouth, and the patients went around with theirs protruding somewhat and resting upon their lower teeth. The papillæ were enlarged and very sensitive, especially the group situated on either side and near the middle. This came on generally on the second day, and lasted about a week. This complication did not seem to occur with any particular type of the disease, although some angina existed in most of the cases. The doctor had also suffered from a similar attack. I was sorry not to have had sufficient time to make further inquiries into this particularly interesting feature of the disease, but Dr. Burke was one of the last men visited by me. I remember, however, mention having been made of a similar case by another observer, but at the time attached no further importance to it.

Statistics from Deaths Reported.—It might be interesting, perhaps, to read a few statistics tabulated from a report which I am preparing for the Board of Health, regarding the various deaths reported as due to influenza. The newspaper reports were in most cases grossly exaggerated, and simply served as sensational food for the masses.

The number of deaths reported to the Health Board as due to influenza during the epidemic was, 121.

Of these, I have investigated 86 through their attending physicians, and find that the causes are somewhat as follows:

Lobar pneumonia	33
Lobular	21
Bronchitis	13
Meningitis	4
Other diseases	15
Total	86

Of the remaining 35 deaths, I find from the death certificates that they resulted from the following diseases:

Pneumonia	19
Bronchitis	8
Other diseases	8
Total	35

Of the 33 deaths reported as due to lobar pneumonia, I find that 28 of them, or eighty per cent., were in men, that only 4 of them were over fifty years of age, and only 1 was under twenty, he a child of but seven days. The majority were between the ages of thirty and forty-five.

The duration of the disease was from two to five days in most of the cases, the quickest fatal case being of one day's duration, and the slowest of eleven days.

In Lobular Pneumonia, on the other hand, 15 of the 21 deaths were in women, and of the 6 occurring in males, 4 were over fifty years of age. The general age also differed very much, as they were in most cases younger or older than those of the lobar variety. The duration also differed, the disease generally not covering as long a period.

Bronchitis also seemed to be more fatal in women, as in 13 cases, 9 were in women. It was, also, especially fatal in the aged, most of the deaths occurring in women over fifty years of age.

Meningitis.—Four deaths were due to meningitis. They were all in males. Three of them were between the ages of twenty-four and fifty, the other, a child of three years. The average duration was five days. The remaining 15 deaths were as follows:

Valvular disease of the heart	2
Phthisis	2
Dysentery	2
Nephritis	2
Sarcoma	1
Eclampsia	1
Peritonitis	1
Pleuritis	1
Influenza	2

Thus we see that there were only 2 deaths due directly to influenza, and of these 1 was in an Italian, sixty-one years of age, in a weakened and debilitated condition, the other in a baby of eight days. In these 15 cases above mentioned, the influenza was the determining cause, and frequently made rapid work, some of them succumbing in a few hours, apparently from the shock of the onset.

In reviewing the history of the manner of dying in these cases, one cannot but remark how many of them were due to "heart failure" and a peculiar "choking-up," as spoken of by the various physicians in relation to deaths in broncho-pneumonia and bronchitis, causing death by asphyxiation.

This would seem to point to the fact that the prostration occurring with the influenza is the most dangerous

factor in the disease, and that it seems to exert an especially depressing influence on the action of the heart and lungs, as was shown by the tendency to "heart failure" and the diminished power of expectoration.

107 West Fifty-fourth Street.

Clinical Department.

A CLINICAL STUDY.

By H. H. SPIERS, M.D.,

Edinburgh, O.

R. E——, farmer, aged fifty-eight, in good health, but not very muscular, called on me last February with a troublesome eruption, about the size of a silver dollar, on the wrist of the left hand. It was oval in shape, dark red in color at the base, with minute white vesicles rising over the entire surface, alternately appearing and disappearing. Various ointments were used for this eruption. At the suggestion of Dr. A. an ointment of sulphate of zinc, 3 j. to vaseline ℥ j. was used. No particular result, only it made the wrist extremely tender. The mercurial ointment proved the most effective. After a time the sore slowly healed. On March 19th Mr. E—— consulted me relative to some difficulty of kidneys. An occasional pain in that region; no fulness; no particular side; at times scanty urine. Mr. E—— thought he had no serious difficulty, for he had experienced similar pains and scanty urine many times before. His remedy had been ten to fifteen drops of spirits of turpentine, taken once or twice a day. It always afforded relief. Gave him a mild laxative in pills containing balsam copaiba. About two weeks later he reported, "Feeling much better." Again, in about ten days, "Am feeling some better." On April 19th, "Come and see me." On April 18th Mr. E—— ploughed his garden. Was feeling as well as usual. On the night of the 18th he was in an agony of pain, tossing and rolling from one side of the bed to the other without sleep. "What can be the cause?" was his first question. Saw him in the afternoon. In appearance, since March 19th, one month, Mr. E—— had lost in flesh. His face indicated great anxiety. Was in but little pain at that time, but had passed a very hard night. Pulse 65, full and regular; temperature about 100° F.; tongue heavily coated; appetite small, almost *nil*. On the left side was a distinct tumor extending from the crest of the ilium, high in the lumbar region, and from the linea alba to the spinal column. The pain was low down, near the sigmoid flexure of the colon. On palpation no tenderness was felt at any other part except this. On percussion of right side the bowel-sound was heard, and no atrophied or enlarged liver could be detected. On percussion of left side a dull thud was heard. The tumor seemed a hardened mass. What could it be? The first thing that entered my mind was, Is it possible that this tumor is fluid, and is due to the rupture of a blood-vessel? But the countenance did not indicate that. There is always that pallid, death-like look in all severe hemorrhages. On asking the question, "Have you hurt yourself by lifting in any way?" "Not that I know of, have not been lifting." Hemorrhage excluded. My next thought was: Has this man an enlarged spleen? On questioning him he replied that he never had fever or ague; never had a chill in his life. On closer percussion I could detect a line of higher intensity between the tumor and true location of spleen. Enlarged spleen excluded. I then said it must be an obstructed bowel. The pain is low down the seat of the obstruction. Questions were again put. "Have you felt any fulness in this region in the past?" "For the past two weeks on buttoning the waistband of my pants there has been a fulness." "Has there been any tenderness?" "For the past month, in reaching over a bin to get oats, there has been a tenderness." "Have you had a daily evacuation of the bowels?" "Not daily, about every other day, and it seemed to me I did not pass one-half as much as I ought." "Have you ever experienced any difficulty with your kidneys other than the above-named?" "None whatever."

In my judgment this fulness is due to retained fecal matter; and that the case before me is a case of obstruction at the sigmoid flexure of the colon. The treatment was in accordance with the opinion. The hips were elevated with a pillow; injections were used every two or three hours during the day, and ordered to be retained as long as possible. Soap and water were used. A small opiate at night, and no nourishment except milk and lime-water, with an abundance of pepsin. He was to report by telephone in the morning if no better. Saw him the next morning, and asked for consultation. Dr. A. sent for at 10.30 A.M. The doctor examined the patient, and informed me as follows: "A very bad case. A case of large white kidney. We can do nothing for him but to sit down and wait and let him die." Of course, I differed somewhat from the doctor, and said: "He may have a large white kidney, but at present he is suffering from obstruction of the bowels." The doctor replied: "Mr. E—— may have some impaction of the fæces, but I feel assured he has a large white kidney." The improbability of the diagnosis seemed to shock my sense of fitness. "Mr. E—— to-day is doing the bulk of the work on one hundred and twenty acres of land; is in comparatively good health, and in eighteen hours has a large white kidney. Large white kidneys do not grow so rapidly." "Yes," said the doctor, "but this kidney has been growing a long time." "True, but people with large kidneys generally rest in easy-chairs." Thus we differed. But, thanks to our mutual good-nature, we agreed on treatment. In the evening of the same day—April 20th—I called Dr. S., who was informed as to the history of the case, and was also given the individual opinions of the attending physicians. He was, therefore, requested to examine the patient with all possible care. He did so. His report was: "A case of enlarged spleen." I then referred the doctor to the fact of discovering a line of dulness, of higher intensity, between the tumor and the true location of the spleen. Dr. S. again went into the room and examined in the location designated, but neither of us could detect any difference in the percussion note. The tumor was evidently increasing in size, or, at any rate, was becoming more solidified and extended in the direction of the spleen. I felt satisfied Dr. S. was mistaken. On Dr. S. asking the question, "Did you ever see a case of obstruction of the bowels like this?" my answer was, "Yes, in the dissecting-room."

At Dr. S.'s suggestion injections of sweet-oil, salts, and infusion of senna were used. The case continued day after day, the bowels not acting, the pulse becoming quick and irregular, the temperature 102°, with little variation, the extremities cold, and the general condition pitiable in the extreme. Dr. A. attended the case with me every day, and announced the patient would probably live but a few hours. It seemed to me wrong under the circumstances not to inform the family of the true state of things. The information was therefore given. Mrs. E—— called Dr. W. So far as I know, Dr. W. knew nothing of our opinions. He was given a brief history of the case and requested to examine. His words were: "The worst case of obstruction of the bowels I ever saw in my life. The patient will certainly die." At Dr. W.'s suggestion a rectal tube was passed as high as possible, and injections used through this. At the end of the twelfth day from taking the bed the bowels began to act. All the passages were fluid and very offensive. It made lively work for the attending nurse. On one or two occasions he passed an orange-colored fluid, with shreds of mucus and large quantities of slime. After each passage the patient expressed great relief. Milk and lime-water were taken with a zest. After a day or two of almost continuous operation of the bowels the tumor was much reduced in size. The large intestine could then be felt its entire course. But it was also evident that there was something more than obstructed bowel. A tumor still remained.

Dr. S. was again requested to examine. He acknowledged his mistake in enlarged spleen. In his judgment the tumor contained fluid. Dr. A. had expressed the same opinion several days previously, and I had denied it. But in all cases of tumor of an uncertain nature an exploring needle is perfectly proper. Accordingly, at about the end of three weeks of Mr. E——'s sickness, Drs. S., A., and myself proceeded to aspirate. Result: One gill of blood containing an excess of fibrin. Dr. A. was not satisfied. The needle should have been passed higher up. He knew there was fluid. Three or four days later Dr. A. and myself passed a needle in the place designated, first using an injection of morphine and cocaine. No fluid found. Another instrument was used with a larger needle. Result negative. Now, I do not assert there was no fluid present, but certain it is, none was found. The case continued about the same. Occasionally there would be a rally. Then a little hope would be expressed. One great feature in the case was the hopefulness of the patient. He felt assured that he would recover. Directions are minutely followed. Nourishment is taken at regular intervals. A small hypodermic of morphia used every night. Gastro-enteritis supervenes. It seems to extend the whole length of the alimentary canal. Immense quantities of blood, slime, and mucus are passed. The passages are offensive in the extreme. Where does the blood come from? the tumor or the ulcerated bowel? The patient declares these discharges afford relief. They certainly do not seem to make him weaker. On one point Drs. A., L., and S. agree: The tumor is diminishing in size. A. still clings to large white kidney. S. says cancer of omentum, involving the bowel. No trouble with kidney unless it prove cancer. L. says we must let a post-mortem clear up the case.

The urine is separately examined by the three M.D.'s named. L. discovers with microscope a small amount of oxalate of lime. Otherwise normal. A. says the specific gravity is a little below normal, but is not far from right. S. pronounces it normal. At no time during illness is the amount excreted in excess. The urine continues as above until within five or six days of death. It then assumes a darker color, and on examination blood is found. Ten days before death Mr. E—— has a decided chill. On examination a soft spot, with distinct fluctuation, is found on the left side in the lumbar region. A hypodermic is again given, and aspiration made by A. and myself. About one pint of disorganized blood is withdrawn. This seems to afford a little relief, but it is very evident at every visit that the end is near. He passes away the morning of June 3d. Post mortem held the afternoon of the same day. Present: Drs. W. and son, A., B., and S. The first thing observable is the great emaciation. Although the sickness is comparatively brief, the digestion fair, the amount of nourishment taken at times full, it is evident to all Mr. E—— is gradually losing flesh. This was seen at the first, and inunction of sweet oil and quinia was used every two or three hours during the entire sickness. But emaciation continued.

On opening the cadaver the diseased condition and abnormal position of left kidney is at once noticed. The terms used are comparative. No scales were employed. The left kidney, enlarged to three times its natural size, with one-third of the organ gone, lay about two inches to the left of the umbilicus, close to the anterior wall. The opposite kidney was in its normal position, a little enlarged, but healthy. Spleen and omentum normal. Liver twice its natural size, and indentations on its surface made by the ribs. But if I may speak of any one thing to be thought of and speculated about more than another, it is the presence of at least one quart of sanious clotted blood in the abdominal cavity, without a surrounding cyst, in connection with the colon by many openings. For three weeks the fluid blood had passed with the fæces through the openings in the colon. The clot had been retained. Could it be possible for a patient to live in this condition? He did live, and entertained a hope of recovery. What caused this collection of blood? What made these many openings in the colon? Why the abnormal position of the kidney? What is the ailment? These and kindred questions give my article the above title.

INTRA-ABDOMINAL ENUCLEATION OF A UTERINE FIBROID.

By D. TOD GILLIAM, M.D.,

PROFESSOR OF OBSTETRICS AND DISEASES OF WOMEN, STARLING MEDICAL COLLEGE, COLUMBUS, O.

THE proverbial uncertainty attending the diagnosis of abdominal tumors, and the many unforeseen and unlooked-for complications revealed by the abdominal sections, not infrequently necessitate a radical change of tactics or a total abandonment of the operation. It sometimes happens that none of the recognized methods will meet the exigencies of a particular case, and then the operator, if he would proceed, must strike out boldly on a new line, governed only by certain cardinal principles which may not be lost sight of.

The following case illustrates, I believe, a technique hitherto unpractised, and may be of service to anyone encountering a like condition of things. M. E. R——, single, aged thirty-seven, has been the subject of a uterine fibroid for the last sixteen years. Being a milliner, and dependent on her own exertions for a livelihood, she has experienced much embarrassment from her affliction, and much of the time, especially during the last year, has been confined to her bed. After diligently trying all known methods of treatment without avail, she became importunate for an operation. This I declined until, seeing that she was determined, and out of compassion for her deplorable state, daily growing worse, I finally consented to operate.

On Sunday, November 24th, at 10 A.M., in the presence of, and assisted by, Drs. Kyle, Follet, Rankin, and E. M. Gilliam, I made an incision four inches long through the abdominal walls and introduced the hand. General adhesions existed, and the incision was carried upward and downward from the pubis to two inches above the umbilicus. An attempt was now made to break up adhesions, and by dint of much force and perseverance the tumor was freed anteriorly and to some distance on either side. It became apparent, however, that nothing short of dangerous violence would separate the agglutinated intestines, and the growth was so firmly bound down in the region of the large pelvic vessels that I was compelled to desist from further efforts in this direction.

Now the alternative presented itself of retreating entirely or resorting to a bold expedient which suggested itself at the moment, but which I did not remember ever having seen practised or recommended. Rather than have my patient awake to the appalling consciousness of utter failure I chose the latter, the more readily in that it seemed feasible and not fraught with particular danger. Perceiving that only a thin stratum of fibrous tissue covered the growth anteriorly, I proceeded to work through this to the face of the tumor proper. I now proceeded to enucleate, which I was enabled to do without much difficulty, and finally arrived at the pedicle, which was long and narrow and extended across the fundus uteri flush up to the right ovary. It will be observed that the growth sprang from the fundus, and, although not properly subperitoneal, for the reason that posteriorly it was covered by quite a thickness of muscular tissue, it did not carry the broad ligaments up with it.

At this juncture a bystander inquired how I should deal with the capsule and with the pedicle. I had made up my mind on this score before commencing. Neither the capsule nor the pedicle could be brought into the abdominal walls on account of adhesions, so that they must be dealt with intra-peritoneally. The pedicle was transfixed and tied with silk, but, owing to the proximity of the ovary, this was included and cut away with the tumor. The capsule was now carefully inspected, all

bleeding vessels tied, and oozing tracts transfixed, leaving, after thorough cleansing, a comparatively dry, clean surface In the meantime it had retracted to less than half its original size, due, doubtless, to the muscular elements it contained.

It was now closed by a continuous over and over suture, and the pedicle was whipped in like manner. A small triangular space was left at the junction of the pedicle and the lower angle of the opening in the capsule, which could not be brought together because of the retraction. This left a communication between the cavity of the capsule and that of the peritoneum. It gave me much uneasiness, not so much from fear of infection, for, owing to the retraction of the capsule and thorough internal quilting of the same, there was practically no cavity left, and that was not likely to prove a discharging surface. My fear was that a loop of bowel might find its way into the opening, and become strangulated. The toilet of the peritoneum was now completed and the abdomen closed, a large-sized glass drainage-tube being insinuated as low down as possible. The operation had lasted one hour and forty minutes, and the patient was put to bed with a feeble but normally frequent pulse, and not inordinately depressed. She took the anæsthetic badly, becoming very rigid in the initial stage, and twice during the operation it became necessary to invert her on account of suspended animation. She was now left in charge of Dr. Kyle, her attending physician, and I returned to the city. Daily reports by telephone were encouraging until the fifth day, when I received a message that the patient was vomiting stercoraceous matter, and sinking fast. I suggested that the doctor remove a few stitches and search for the incarcerated bowel in the opening above the pedicle. This he did, but found it clear; and, although the vomiting ceased, the patient continued to sink, and expired on the evening of the sixth day. An autopsy was not had, for the reason that the undertaker had filled the abdominal cavity with salt before the doctor arrived.

Notwithstanding the unfortunate termination of this case, I am persuaded that it was not due to the capsule, and when we consider the celerity with which enucleation can be accomplished and the avoidance of dangers incident to the breaking up of very firm adhesions to important viscera and blood-vessels, it, I think, commends itself as the safer line of practice.

A CASE OF INTERMITTENT FEVER, WITH A SCARLATINA ERUPTION.

Dr. J. E. Thompson, of New York City, reports the following case under the above caption: "In May, 1882, a dispensary patient wanted me to prescribe for her brother, who, she said, had malaria, having a chill, fever, and sweat every other day; the paroxysm beginning in the morning and lasting until 4 or 5 P.M. Two days afterward she called again, asking me to go to her home, as her brother 'was broken out with a rash,' and she was afraid that he had a fever. On calling, two hours afterward, no trace of the eruption could be found, and the boy's skin was perfectly clear; temperature and pulse, about normal; but with offensive perspiration. On close questioning I learned that an eruption always appeared with the chill, growing rapidly worse, and disappearing with the fever.

"I left word that I should be sent for at the commencement of the next chill, which occurred the second day after my visit. I found the patient in bed, complaining of the severe cold; cheeks flushed, and the skin of the chest and arms had the appearance of an eruption, though not well defined. At the commencement of the febrile stage the whole body became scarlet, and the throat was red and angry-looking; strawberry tongue; temperature, 104° F. Had I seen the patient then for the first time, I should have pronounced it scarlatina. With the abatement of the fever the eruption gradually disappeared, and when the sweating stage was at its height the skin was clear.

"I have never seen nor read of a similar instance, although I have seen three cases of intermittent fever with slight eruptions, but not resembling scarlatina. How much the mind had to do with this particular case, I do not know, as the patient, a boy aged fifteen, of a very nervous temperament, had lost a younger sister by scarlet fever a few months before his illness. My theory is, that it was due to a badly nourished body, intensified by a dread of scarlet fever, as the eruption disappeared upon giving the patient proper nourishment and plenty of it before the intermittent fever was cured."

Progress of Medical Science.

Creolin in Diseases of Children.—Dr. Schwinz, of Prague, gives some important details as to the use of creolin in the Czech Foundling Hospital, of which he is director. The affections in which he tried the drug were the following: 1. Ophthalmo-blennorrhœa neonatorum: In ten cases irrigations of a one per cent. solution of creolin were tried; only two mild cases recovered in from four to six days. In the other eight cases the remedy failed, even when used for four or five weeks, so that the usual method (boracic acid with the nitrate of silver) had to be resorted to. It was evident that the irrigations of creolin caused greater pain than the instillation of a from one to two per cent. solution of the nitrate of silver. 2. Thrush and Bendar's aphthæ: In eleven cases in which the use of the chlorate and the permanganate of potassium, as well as boracic acid, etc., had formerly proved futile, washing of the mouth and pharynx with a one per cent. solution of creolin for from five to seven days resulted in complete cure. 3. Omphalitis of newborn children: In all four cases a complete cure was effected in four days by rubbing the navel and the surrounding parts with pure creolin. 4. Erysipelas of the navel: The affected parts were rubbed twice a day with pure creolin. The effect was excellent, and although the application was continued for about six days, in none of the cases did symptoms of poisoning occur. 5. Acute gastro enteritis: In nine cases the drug was used as follows: ℞. Creolini, from two to three drops; cinnamon-water, 80 grammes; syrupus altheæ, 20 grammes. S.: A coffeespoonful every hour. In the case of older children: ℞. Creolini, from 0.5 to 1 gramme; white sugar, elæosacchari fenic, āā 2.5 grammes. M. fiant pulveres Mitte 10. from one to two powders a day. In general the results were very satisfactory, the only untoward symptom observed being vomiting, which occurred in some infants at the breast. 6. Creolin proved very valuable in surgical cases in quite young children in which carbolic acid and sublimate could not be used. A solution of from one-half to one per cent. was quite sufficient for disinfection of the field of operation, the wound, etc. Recovery occurred very rapidly. Neither erythema nor eczema was observed. The author, among other things, mentions the case of an excessively large cephalhæmatoma in a child eight days old, in which healing by first intention occurred within five days after irrigation of the cavity with a little of a one fourth per cent. solution of creolin. — *Vienna Correspondence of the British Medical Journal.*

Dry Operations have been lately advocated by Landerer, of Leipsic, among others. His reasons for rendering operations as dry as possible are not without weight. He points out that the employment of all sorts of antiseptics may be dangerous under certain conditions, and that it is advisable to avoid them as much as possible. The employment of sterilized fluids in large quantities is inconvenient and messy, and there are many advantages in keeping the field of operation quite dry. The essential part in the dry method is, immediately after the first in-

cision, to keep every part of the operation field, not for the moment under the knife, under pressure by means of antiseptic gauze—dry sublimate gauze is what he recommends. By this means the wound can be closed more quickly, as the plugging will have arrested the bleeding, and drainage will frequently be avoided altogether. The suturing then takes place, after which a moderately firm compress is applied. In this way the patient is less messed and cooled, there is less loss of blood, and above all, no germs can enter from the moment the plugging is applied. The bleeding is more quickly arrested, and the duration of the operation is shortened, while at the same time healing is rendered more rapid and certain.—*The Medical Press.*

Renal Dropsy.—Regarding the pathology of renal dropsy, Dr. Auld believes that that condition of the blood to which the term anæmia is applied must be regarded as an important factor in the production of the anasarca and dropsy of Bright's disease. First of all, it is possible in Bright's disease, as in other conditions, that certain retained products of the organism, or their toxic derivatives, may exert a deleterious influence on the tonicity of the vessel walls. Then we have to consider the grave alterations in the vital and physical properties of the blood when anæmia is combined with hydræmic plethora, and the disturbances of the circulation resulting therefrom. By the progressive diminution in its corpuscles, the vital energy of the blood itself is impaired; and by the advancing attenuation of its proteid constituents, the specific gravity of the plasma becomes relatively lighter than that of the corpuscles themselves, and its physical relations to the plasma circulating in the lymph canalicular system outside the vessels are materially disturbed. Under these abnormal conditions the circulation of the blood-corpuscles is impeded, the whole vascular tension becomes increased (Hamilton), and transudation of the fluid within the vessels readily takes place; and such transudation will, moreover, be rendered still greater according to the loss of tonicity of the vessel wall, in whatever way we may consider that condition to be brought about. With increasing anæmia the dropsy becomes augmented, and is regulated in its distribution by physical laws. Where the *vis a fronte* is greatest and the circulation feeblest, there the dropsy will be found most marked; namely, in the extremities furthest from the heart. Here the venules become hyperdistended, and are unable to absorb and transmit the lymph which pours forth excessively from the capillaries. Should this state of matters continue, the circulation will fail nearer and nearer the heart, until the fluid accumulates internally, in the serous cavities, lungs, and other organs, when death is imminent. A most important and valuable contribution to this subject has been published during the year by Dr. Saundby, whose lectures on Bright's disease handle the subjects of albuminuria, uræmia, renal dropsy, and the cardio-vascular changes in an admirable manner. The latest information on these matters will be found set before the reader of these chapters in a terse but very lucid style, while those devoted to the special pathology of the various forms of Bright's disease are enriched by the author's own extensive personal experience. It is a work which will be extensively read and referred to.—*The British Medical Journal.*

Observations on Human Bile.—S. M. Copeman and W. B. Winston have made a series of observations and analyses on bile obtained from a woman who suffered from obstruction of the common bile-duct due to a gall-stone. Mr. Sydney Jones cut down on the gall-bladder, stitched its edges to the wound, and then laid it open. Six or seven ounces of a glairy, semi-transparent fluid, free from biliary coloring matter, was evacuated, which contained leucocytes and a few crenated red corpuscles. Although no gall-stone could then be detected, it was found post mortem close to the junction of the bile-duct with the intestine. The day after the operation bile began to flow, and daily increased after that time. No trace of bile could be found either in the urine or fæces, so that the authors were able to collect the whole of that secreted. They have determined the amount in twenty-four hours for several days, the variation in the flow, and its physical and chemical characters. One of the most curious points noted was the presence of urobilin in the urine, which in this case could not have had its origin in bile-pigment, but must have been a direct metabolite of hæmatin. Calculating from the quantity obtained, it is estimated the normal amount of bile secreted by the liver is about two and a half pints *per diem*. The rate of flow varies according to the time of the ingestion of food, a rise having generally been noted between one and two hours after a meal. The secretion is not a continuous one, the bile being extruded into the gall-bladder by the repeated peristaltic contraction of the bile-ducts. The color of the bile was olive-green, biliverdin and not bilirubin being the pigment present in greatest quantity. Putting side by side the results of the analysis of this bile and of normal human bile, as given by Frerichs, the following is the result:

Constituents.	Present case.	Frerichs.
Sodium glycocholate..... } Sodium taurocholate..... }	0.6280	9.14
Cholesterin, lecithin, and fat	0.0990	1.18
Mucus	0.1725 }	2.98
Pigment	0.0725 }	
Inorganic Salts.....	0.4510	0.78
Total solids.....	1.4230	14.08
Water (by difference).....	98.5770	85.92
	100.0000	100.00

The low percentage of solids, especially of bile-salts, is accounted for in the manner suggested by Schiff and others—that there is normally a circulation of bile going on between the liver and intestine, "a large quantity, at any rate, of the bile-salts which pass into the intestines being reabsorbed and yet again secreted." This idea is supported by the fact that cholalic acid is found only in very small quantities in the fæces. No such circulation could have taken place in the present case. Bile from the gall-bladder is always more concentrated than that from a fistula, probably because a portion of the water is reabsorbed during its sojourn in the gall-bladder. Bile is necessary for the assimilation of fat: the fæces in this case contained much undigested fat. The authors think its purgative action is more than doubtful, and by cultivation experiments they have proved that it is not a true antiseptic. Bacteria grow just as well in the tubes containing bile as in those free from it. The fæces were free from stercobilin, showing that this is formed from bile-pigments in the intestines. The nature of the diet is not, however, described. The original paper is found in volume x. of the *Journal of Physiology*, and the above abstract is published in the *Birmingham Medical Review*. Dr. McMuren has also (*Journal of Physiology*, vol. vi.) described the results of an examination of bile obtained from a biliary fistula, the patient having had cholecystotomy performed upon her for impacted gall-stones by Mr. Lawson Tait. In that case no bilirubin was present, the color of all the specimens being greenish or yellow. The specific gravity was found to be (for the twenty-four hours' bile) 1.0065 (in the present case it ranged from 1.0085 to 1.105), and the total solids amounted to 1.4915 per cent., the water to 98.5085. Moreover, it appeared that the chromogen of a urobilin-like pigment was present, and that the biliverdin also was (partially at least) present as a chromogen.

The Latest Strategy of a Paris Paper for attracting readers is the engagement of two eminent physicians to attend gratuitously upon its annual subscribers. Recently the manager of the paper gave notice to one of the physicians "not to prescribe for B any more; his subscription has expired." The doctor replied: "So also has B."

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

HOSPITAL OUT-PATIENT REFORM.

WHETHER this question is still worthy of discussion, after all that has been said, pro and con, is somewhat dependent upon the spirit in which it is approached. If a question cannot be considered as settled until it is settled rightly, there is yet much to offer. In season, and out of season, we have advocated any and all projects in which there was a justifiable promise of relief, but now, as another year has come and gone, we regret that we cannot see that a single step in advance has been taken.

We have read, with some interest, certain figures published in a recent number of *The Lancet* concerning the state of affairs in Manchester. In that city there is a Provident Society, which co operates with the various institutions in preventing the abuse of medical charity. In 1875 the percentage of applicants for treatment who were found, upon investigation, to be ineligible for gratuitous relief, was over forty-two per cent. Ineligibility consists in the receipt of over a certain amount of wages. All above this are considered able to look after themselves, and are refused hospital treatment. All below are received. Under these restrictive measures the annual percentage of ineligibles had fallen from forty-two in 1875 to thirteen and one-half in 1885. Here in New York our nearest approach to the Provident Society is the Charity Organization Society, which deserves a much more cordial support, from both the profession and the laity, than it has yet received.

But the old dispensaries all flourish like a green bay tree, and new ones spring up on every hand. We have been interested in reading the rules posted in one of the more pretentious ones recently opened in the northwestern part of the city. The medical attendants are forbidden to take pay for their services, to treat any of their private patients there, to "run off" any patients to other institutions, etc., but no allusion whatever is made to the propriety of separating the worthy from the unworthy. A survey of the daily attendance would convince any observer of the advisability of supplying this omission.

Some few years ago a special meeting was held at the Academy to consider this matter. Physicians and laymen both attended it, and the hall rang with philippics against the presuming public, who thus imposed upon medical charity. The characteristically American device of appointing a committee was adopted, and we have yet to learn of any progress in the matter.

We have before outlined what we believed to be a proper and practicable method of alleviation. All dispensary applicants belong in general to two classes. One is so sick at the time of the visit as to require immediate attention. This should be given promptly on simple humanitarian grounds. No red tape of any kind should act as a hindrance. The other class is not so ill but that a delay of treatment for, say twenty-four hours or till the next day, could occur without prejudice to their recovery. In the meantime let them be investigated, and their homes visited. This would be necessary in only a portion of the second class. Such a visitation would require men and means, but it would go to the root of the matter. Even then a co-operation of all our institutions would be necessary to secure definite results. It is a sad fact that our progress in medical science is mated with an equal advance in medical mendicancy.

PRELIMINARY MEDICAL EDUCATION AGAIN.

IN 1878–79, according to the report of the Commissioner of Education, there were 13,321 matriculated medical students in this country, of whom 884 had taken literary or scientific degrees. In 1887–88, the number of students was less by more than two thousand, being 11,172, and the number who held literary or scientific degrees was greater by nearly two hundred, being 1,073. These figures, though not very accurate, and far from what official figures should be, certainly confirm the common observation that more college-trained men enter the profession than was formerly the case.

This is an encouraging sign, and shows the presence of a tendency which we trust will become stronger every year.

A teacher in one of our local medical colleges has stated in *Harper's Young People* that a college education is not necessary or advisable in most cases. It is sufficient, he thinks, that the boy get such an amount of education as would fit him for an ordinary classical college, then, at the age of eighteen, he may enter a medical college, from which he will probably graduate and begin practice three years later.

The *Journal of the American Medical Association*, commenting upon this, takes much the same view which the MEDICAL RECORD has advocated, and which we still regard as far the wisest. It is that every young man who intends to study medicine should make a strenuous effort to secure first a classical education. Since the requirements of the larger colleges are now so severe that he can hardly graduate before he is twenty-two, he will do better in most cases to enter a smaller institution where he can graduate at the age of twenty or twenty-one, and his last year should be so directed as to make it count upon his medical studies. In this way he will gain the intellectual training and social advantages of college life, and still be able to start in his profession by the age of twenty-four or twenty-five.

Parents in deciding about the education of a son have to consider not only how to make him the best "medicine-man" and pill distributor, but also how to make him learned, wise, discreet, self-contained, capable of dealing practically with all kinds of people, and also of enjoying a little of the higher intellectual life. The art of medicine

depends quite as much on knowing how to meet and handle men as on knowing how to prescribe drugs. The worst physicians are those whose minds from early and immature age have been steadily crammed with technical knowledge, until they see nothing except through ophthalmoscopes, or laryngoscopes, or microscopes, and hear nothing except with the ear to the chest.

Medical success is not dependent on college education nor do we mean to discourage at all those who have not been able to secure it. Some do not need it or are even injured by it. But it is a preliminary which it is advisable always to try and obtain. And observation shows that there is an increasing desire to obtain it.

WHEN DOCTORS DISAGREE.

We are in receipt of a pamphlet from Dr. J. J. Chisolm on "Persistent Headaches and How to Cure Them." The general teaching of this contribution to positive therapeutics is that the headache eye is the astigmatic eye, and that the great cure for headaches is to wear correcting glasses. Even slight degrees of astigmatism are considered of great importance, and the utility of frequently prescribing weak cylindrical glasses is extolled.

We are also in receipt of a pamphlet from Dr. J. H. Woodward, on "Eye-strain and Functional Nervous Diseases," in which are reported one hundred and fifty consecutive cases of eye-strain treated for the relief of headache with eighty-five per cent. of cures. In this article much stress is laid upon eye-strain from imperfect action of the ocular muscles, and despite the excellent results obtained one does not gather that astigmatism is at all a dominant factor in the causation of the head pain.

Another writer upon sick headaches asserts that "latent hyperopia" is an extremely common cause, while esophobia and hyperphobia are not rare. In neuralgias Dr. A. L. Ranney finds astigmatism in only twenty per cent. of cases, while some muscular errors were present in nearly every case.

Meanwhile the general practitioner treats most of his cases of headache upon the general principles of relieving blood-taints, digestive disorders, and nervous depression.

SOME COMMENTS ON A POPULAR PILL.

A few years ago a medical writer made some comments upon the inutility, from a physiological standpoint, of belladonna in cases of constipation. In poisoning from large doses of belladonna no diarrhœa or action upon the bowels is produced, while the probabilities are that the intestinal secretions are lessened in amount. Physiological experiments as to the action of belladonna on the muscular coats of the intestines are contradictory, there being very good evidence that the drug produces actual sedation. The idea that when given to man in ordinary medicinal doses it at all lessens the inhibitory action of the splanchnics entirely lacks confirmation.

Dr. Henry M. Field, in a recent issue of *The Therapeutic Gazette*, criticises the composition of the much-used pill, consisting of aloin, gr. $\frac{1}{6}$, extract of belladonna, gr. $\frac{1}{8}$, and strychnine, gr. $\frac{1}{60}$. The aloin is not sufficient, he thinks; on the other hand, the belladonna is too large in amount, since if a patient has to take gr. $\frac{1}{8}$, two or three times in twelve or eighteen hours, he will be likely to get unpleasant physiological effects. The use of the alkaloid strychnia he regards as entirely futile, since strychnia is very insoluble, water hardly affecting it in the ratio of one to five thousand. Dr. Field, therefore, would give of aloin, gr. $\frac{1}{3}$; sulphate of strychnia, gr. $\frac{1}{40}$; extract of belladonna, gr. $\frac{1}{10}$, and he adds of pulv. ipecac, gr. $\frac{1}{2}$. It would appear that in this process of emendation the belladonna might as well be left out altogether; while we fancy that the average New York bowel would be too stormily affected by a third of a grain of aloin. The criticisms above made show at least the harm that comes from the routine prescribing of much-advertised and neatly prepared pills. As a matter of fact, a grain of powdered aloes, with a little rhubarb or ipecac, will usually act quite as well as the compounds given. Dr. Field's caution as to the use of a soluble salt of strychnia, rather than the insoluble alkaloid, is one worth bearing in mind.

THE TREATMENT OF TYPHOID FEVER IN AUSTRALIA.

A great deal of fault has been found with the statistics so numerously produced in support of the cold-bath treatment of typhoid fever. While many of them are undoubtedly worthless, it is impossible to receive them all with scepticism; and there is a growing feeling, even among the most conservative, that the cold-bath treatment of typhoid fever has achieved a high place in therapeutics.

Dr. T. W. E. Hare, of Brisbane, Australia, has recently brought forward statistics which apparently show that the water treatment is efficacious in that part of the world.

The Brandt treatment was introduced into the Brisbane Hospital, January 1, 1887, and has been continued ever since. In this hospital typhoid fever was treated expectantly from 1882 to 1886, with the result of giving a mortality-rate of 14.8 per cent. among 1,828 cases. From January 1, to June 30, 1887, the bath was employed tentatively and imperfectly; and the mortality-rate was 12.3 per cent. among 171 cases. From June 30, 1887, to June 20, 1889, the bath treatment was rigidly applied, with the result of getting a mortality-rate of seven per cent. among 797 cases.

The average mortality-rate under expectant treatment in the Sidney, Melbourne, and Adelaide hospitals in the corresponding years 1887 and 1888, among 2,918 cases, was 13.8 per cent. The baths did not much affect the percentage of hemorrhages and perforations, but lessened the deaths from asthenia, pneumonia, heart-failure, etc.

Dr. Hare thinks that it must be conceded that the introduction of the cold-bath treatment, and the fall in the death-rate, during the last two and a half years, stand to each other as cause and effect. Otherwise it would be necessary to assume:

1. That the type of the disease, which, so far as can be judged by the mortality, had for five years been similar to that in the other colonies and in the old country, suddenly underwent a change at the height of the fever season, in January, 1887.

2. That the change was limited to Brisbane.

3. That the milder form of fever has since persisted; and finally,

4. That the alteration in type was of so selective a nature, that while it greatly lowered the mortality from pyrexial causes, it left the dangers arising from the intestinal lesion practically unaffected.

The United States, and perhaps England, seem to be the only countries in which statistics decidedly favorable to the cold-bath treatment are not to be found.

THE UTILITY OF VACCINATION.

Most of the opposition to vaccination and argument against it has come from ignorant and fanatical people who distorted history and misapplied statistics in order to support their views. There have recently, however, appeared two arguments tending in the main to discredit vaccination, yet made by persons who have apparently investigated the subject carefully and more or less impartially. The authors are Dr. Creighton, who contributed the article on vaccination in the "Encyclopædia Britannica," and Dr. Edgar Cruikshank, who has just published a two-volume work on the "History and Pathology of Vaccination." Both these gentlemen take the view that vaccinia, or cow-pox, has no affinity at all with small-pox; hence, *a priori*, there is no reason why vaccination should have any protective influence.

We do not propose to go into any analysis of the arguments put forth by these gentlemen. It is very certain that *a priori* reasoning will not destroy public confidence in vaccination, while it is utterly impossible, in our opinion, for anyone to study impartially the statistics of vaccination and then deny its utility.

The works of Creighton and Cruikshank, however, are likely to modify our ideas of the pathology of vaccinia.

CONCENTRATED ENEMATA OF EPSOM SALTS.

Some years ago Dr. Mathew Hay made a series of experiments upon the use of concentrated solutions of magnesium sulphate given by the mouth. He found that they rapidly drew water from the blood into the intestines. Thus, the bowels having been well emptied, he gave three-quarters of an ounce of the salt, and in half an hour (the time of greatest concentration) obtained an increase from 5,000,000 to 6,790,000 blood-corpuscles; that is, of 1,790,000 to the cubic millimetre. This increase was not obtained if the alimentary canal was not emptied, or if a diluted solution was used. He attributed the concentration to the action of the salt in depriving the tissues of water.

The experiments of Moreau and Lauder Brunton have also shown that magnesium sulphate has the power of producing copious exudation into the intestines, and that its cathartic action results from this and not from any direct stimulus to peristalsis. Acting upon these observed facts, Dr. T. J. Watkins, of Chicago (*Maryland Medical Journal*), began the use of concentrated solutions of magnesium sulphate in the form of enemata. He employed at first a mixture of two ounces of the sulphate and four ounces of water. For more than a year this solution was used by Dr. Watkins at the Woman's Hospital of the city, and with excellent results. He finds it indicated not only in constipation, but in serious intestinal obstruction when there is much nausea and vomiting; and after laparotomy, when sepsis and peritonitis threaten to develop. In conditions of acute and chronic pelvic inflammation the very great watery depletion caused by the injections produces favorable effects. In obstructive dysmenorrhœa it may also be used.

Dr. Watkins says the advantages of this enema are:

1. Its action is local, producing diffusion.
2. Its action is free and seldom fails.
3. Time of action is short.
4. The bulk is small, causing but very little, if any, discomfort.
5. It is as unirritating as a simple enema. Its certainty of action has become so well recognized in the New York Woman's Hospital that it has been used in nearly all the operative cases as the cathartic preparatory to operation, for the last six months.

The following formula is the one now used:

℞ Magnes. sulph. ..... ℥ ij.
Glycerinæ ..... ℥ j.
Aquæ ..... q. s. ad. ℥ iv.
M.

DEATH BY CHLOROFORM.

The report of the Hyderabad Commission on the *modus operandi* of the lethal dose of chloroform, has given rise to much discussion. We have already given the essential fact apparently established by this Commission, viz., that in death from chloroform the first effect is upon the respiration, the heart ceasing to beat later.

We have received a letter from Dr. H. Culbertson, of Zanesville, O., in which he asserts that this view was clearly established by him in a series of experiments upon dogs and pigs, extending over four years, the results being published in 1861 ("Transactions of the Ohio State Medical Society," 1861, p. 35).

Dr. Culbertson's experiments were fourteen in number, and were apparently conducted with care.

Conclusion one is as follows: "That from the effect of chloroform by inhalation, the lungs will cease to act first, and the heart last."

Conclusion thirteen: "The fact that the lungs cease to act first and the heart last, sometimes one being more congested and again the other, would indicate that these organs are affected through the same channel, and not the heart solely at fault."

Conclusion fourteen is, "That restoration may take place after the heart ceases to beat, by the institution of artificial respiration."

Dr. Culbertson's views are thus seen to have been distinctly and categorically stated, and to have been based upon experimental evidence.

It is not true, however, that the opinion that chloroform kills by paralyzing the heart first, has been uniformly taught. In a number of standard works, it is admitted that respiratory failure often occurs first.

But it is now asserted that this must always be the case when chloroform is carefully administered, and that primary heart failure, if it occurs, is due to shock or some accidental reflex influence.

We take pleasure in placing on record again the experiments and conclusions of Dr. Culbertson, for which he is entitled to great credit.

THE PHYSIOLOGY OF A KNOCK-OUT.

The death of a man in "friendly" contest at sparring with gloves, is something unusual in the history of the manly art. Despite the terrific hitting often done in pugilistic encounters, a fatal accident rarely occurs. It is almost impossible for one man to kill another with his fists, provided the other is in good health and his equal physically. The mortality from pugilism is less than from foot-ball. It often happens in boxing by professionals that a man is knocked "silly," in other words, is knocked down by a blow on the side of the neck, which stuns him. The probability is that this is due to the severe concussion and sudden compression of the soft parts of the neck, including the vagus nerve and the cervical sympathetic. Cardiac inhibition, or arythmia, and some degree of vaso-motor paralysis would naturally result. It was by a blow in this region that death was caused in the exhibition sparring contest above referred to.

News of the Week.

Dr. H. Frey, formerly Professor of Histology in Zurich, is dead.

The National Association of Railway Surgeons holds its annual meeting at Kansas City, May 1, 1890.

Professor Otto Madelung, of Rostock, has been appointed to succeed the late Professor Volkmann.

A Pasteur Institute for New York. We learn that a "Pasteur Institute" has been opened in this city by Dr. Paul Gibert, for the preventive treatment of hydrophobia and the study of contagious diseases. Dr. Gibert will be assisted by Dr. G. Van Schaick and Dr. A. Liautard, consulting veterinarian.

Women Doctors in Asylums.—The Lehigh Medical Society (Pa.) formally endorses the proposition. The letter of "X" in another part of this issue will be read with interest in this connection.

A New Medical College has been organized in Keokuk, Iowa. The building is already purchased and the faculty has appointed itself.

A New Medical Law for Utah.—A new bill has been introduced into the Utah legislature providing for a licensed board of Medical Examiners.

A Medical Defence Union has been formed in Manchester, England, for the purpose of defending its membership from charges of blackmail and malpractice.

The Mount Vernon Hospital, N. Y., has been founded, and subscriptions are now in order.

Quadruplets.—Mrs. Newton, of Scottdale, Pa., has given birth to quadruplets, all girls, and every mother for miles around is slightly jealous.

Death of Dr. Landon C. Rose.—Dr. Landon C. Rose, a prominent physician of La Porte, Ind., died February 5th. He practised continuously in his native town since 1848, after his graduation from the Indiana Medical College.

M. Pasteur is reported to be in bad health.

Union Medical Association of Northeastern Ohio.—At the annual meeting Dr. W. T. Barnes of Akron, O., was elected president for the ensuing year.

Influenza Set to Music.—Composer Moroni, Director of the Opera at Smyrna, and whose name felicitously rhymes with harmony, having recovered from an attack of the grip, has expressed his gratitude to Hygeia in a symphony, the melody clearly indicating the course of the malady, from the sneeze to the physician's bill. We trust that the audience is not made to experience "the tired feeling" during its performance, and that it all ends with a cymbalic jingle of coin in the doctor's wallet.

Want Warm Meals and Clean Sheets.—The house staff of the Eastern District (Brooklyn) Hospital, consisting of Ambulance Surgeon Aldrich and Dr. John T. Gibbons, resigned last week. In handing his badge of office to Secretary Baker of the Board of Health, Dr. Aldrich said that he could no longer put up with the meals and accommodations furnished by the hospital authorities. The meals were served cold and the bedding was unclean. He had complained ineffectually to the managers so often that there was nothing left him except to resign. The matter will be investigated.

An Ophthalmological Society has been founded in Kansas City.

The Late Lewis Hall Sayre, M.D.—At a meeting of the New York County Medical Association, held February 17, 1890, the following minute was adopted: The sadly sudden death of Lewis Hall Sayre enrols another name in the memorable list of those who have nobly laid down their lives in devotion to the duties of our profession. In the very flower of early manhood, the brilliantly promising career opening before him is closed in this world by an act of self-sacrifice as heroic as aught that history tells of warlike prowess. The call to relieve another's suffering found him regardless of his own, and, thinking only of the good deed to be done, he perished in its unselfish doing. No greater meed of praise can earthly chronicle record than that a man so honored his high office as to give his life for it; no better assurance of the Heavenly welcome to a good and faithful servant. This Association, to the expression of its own grief at the loss of an associate whose qualities of heart and mind commanded affection and respect, desires to add its profound sympathy with those who are bereaved of the son, brother, and husband, in whom their love and pride were justly centred. P. Brynberg Porter, M.D.,

Recording Secretary.

The Late Charles S. Wood, M.D.—At a meeting of the New York County Medical Association, held February 17, 1890, the following resolutions were adopted:

Resolved, That by the death of our president, Dr. C. S. Wood, our Association has been deprived of one of its earliest and most valued members; one whose constant presence rendered its labors more efficient, and whose counsel warned against many dangers.

Resolved, That his industry and zeal were always an example to us, his contributions to the work of the Association of a high order; and, further, that his deportment dignified its objects.

Resolved, That in tendering our condolences to his family, we trust that their grief may be tempered with the remembrance of his many excellent traits and abundant virtues. P. Brynberg Porter, M.D.,

Recording Secretary.

A Conference of Medical Colleges.—The medical colleges and schools of Maryland, in conference held in Baltimore, February 7th, issued an appeal to the medical colleges of the United States, asking them to send delegates to the approaching convention of the American Medical Association at Nashville, Tenn., with a view of effecting a reform in the methods of medical institutions in vogue in this country. The following subjects are considered as most likely to come up for discussion: 1. Three years' course of six months' session. 2. Graded curriculum. 3. Written or oral examinations. 4. Preliminary examination in English. 5. Laboratory instructions in chemistry, histology, and pathology.

A Fictitious Charity.—The Superintendent of the Brooklyn Sanitarian Hospital and Dispensary was arrested on the 15th, and has been indicted by the Grand Jury for grand larceny for having obtained a share of the excise moneys of the city, amounting to $1,726.55, for his institution by misrepresentation. The indictment says that there is no such institution as the Brooklyn Sanitarian Hospital, and that an alleged report made by the prisoner of cases treated and medicines furnished the poor was purely fictitious. The Grand Jury's presentment says that the prisoner obtained, during the past four years, for his alleged sanitarium, $9,000 from the city.

Dr. Ichabod Patterson Hoyt, City Coroner of Danville, Va., died on February 17th from pneumonia, aged sixty-seven. Dr. Hoyt was born at Painted Post, near Corning, N. Y., February 22, 1823. He graduated in medicine at Geneva College in 1845. He moved to Virginia in 1860, and entered the Confederate army. He was in late years actively engaged in politics.

Sir Robert Kane, M.D., died on February 16th, in London. He was born in Dublin in 1810, where he received a medical education. In 1847 he was awarded a prize by the Royal Irish Academy for discoveries in chemistry. He afterward became President of the Queen's College of Cork, and in 1880 he was appointed by the Crown a member of the Senate of the Royal University of Ireland. He was also a member of the Board of National Education for Ireland.

The Insane Asylum at Little Rock, Ark., caught fire on February 16th, and a part of the building was destroyed. There was no loss of life.

An Old New York School-Book.—The New York *Times* contains an article upon old text-books used in this city. Among the most curious of these was a volume upon "Physicking," which was probably intended to fulfil for that time the function of the modern "First Aid to Injured" manuals. It was published about 1750. It contains prescriptions for various common diseases, which the student committed to memory for future use. The following have been selected directly from the old book: "Cough," it says, "can be cured in the Begin ning with riding moderately on Horseback, and only taking some Ground Ivy Tea, sweetened with Syrup of Horehound. If it be violent it will be proper to bleed 8 ounces." In case of "fever of any kind, it is always best to blister near the Place wherein the Pain lies and by a good bleeding." "Consumption," says the wise author, "is a Distemper slow and sure. Bleed 2 or 3 ounces every three Days; also apply strong Poultices under the arms in order to draw the Mischief that way. For inward medicines let him chew Sassafras Root. His diet should be an Ambundance of Turnips, Raisins, and Licquorice. His drink should be Strong Beer." "For Griping in the Stomack drink a Gallon of warm Whey, and if possible a gallon of warm Water." "The Dry-Gripes is the cruelest kind of Cholick but are now (blessed be God) grown much rarer than formerly. Take 3 Spoonfuls of Bears' Oil or a Decoction of Peach Leaves. If these remedies should fail, you must needs submit to a Tobacco blister. The best Way to prevent dry-gripes is not to meddle with Rum mixed with sugar or lime juice." The following is given as a sure means of bringing a person out of an epileptic fit: "Burn often under the nose chicken feathers, or else leather or rubber, or even the hoofs of any animal." "After every attack of fever and ague bleed eight ounces and take a purge of Indian physick." Here is consolation for a rheumatic: "Bleed ten ounces from the wrist. Next day take a vomit of Indian physick. After this boil a shin of beef in a gallon of water. Put in a pound of garlick and stew to three pints. Take a quarter of a pint morning and evening for three days, when (by the grace of God) you will find relief." Many of the suggestions above given are, after all, not so far removed from what modern therapeutics teaches.

The Late Sir William Gull was a man who believed in doing well whatever he undertook. One of his favorite quotations was:

> If I was a tailor,
> I'd make it my pride
> The best of all tailors to be:
> If I was a tinker,
> No tinker beside
> Should mend an old kettle like me.

and, later on, he often quoted the more classical words:

> If thou do'st purpose aught within thy power,
> Be sure thou do it, though it be but small.

Gull had a curious fascination over his patients. They always, whether hospital or private patients, believed implicitly in him, and thought his opinion final. He is said to have said that for the first few years his practice increased in geometrical progression. He began to practice at 8 Finsbury Square, and while there did a large practice; and when he moved to the West End his practice at the height of his fame was probably larger than that of any other physician at any period. He never lost any opportunity to cure his patient. A doctor sent him a lady, an habitual opium-eater. She was shown into Gull's room. He at once said to her, "Madam, before you say anything to me, let me tell you you must give up the opium I see you take." She was so impressed by Gull's power of divination that she gave it up at once. His management of nervous and hypochondriacal patients was very excellent, and he gained the confidence of one hypochondriac where no other physician could succeed. The patient, like all of his class, wanted much sympathy for his numerous ailments, and yet would have equally disliked to have been told that he was really ill. The patient went to Gull, and afterward informed us that Gull told him "he was a healthy man out of health." He wanted to know why doctors could not have told him that before.

Society Reports.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, January 3, 1890.

GEORGE F. SHRADY, M.D., CHAIRMAN, *pro tem.*

DR. J. WEST ROOSEVELT read a paper on "The Anatomy of the Thorax and Lungs, in Relation to Physical Diagnosis" (see p. 201).

DR. GEORGE L. PEABODY regretted having arrived too late to hear but the latter part of the paper. The portion which he had heard had interested him greatly. Very little could be added to it. The explanation given of the cause of the fluid assuming the position which it did in pleurisy with effusion had interested him especially. He could corroborate the statement that it required an enormous amount of fluid in the chest to cause the diaphragm to arch downward and the intercostal spaces to bulge outward. He had repeatedly found at autopsies very large quantities of fluid, up to a litre or more, without there being any such displacement at all. He thought the element of time had some bearing upon this point. If the fluid had existed for a very considerable length of time in the chest a smaller amount would produce displacement of the diaphragm and bulging of the intercostal spaces than a larger amount would do which had been present but a short time. That meant that constant pressure had, perhaps, a paralyzing influence upon the muscles involved.

DR. BEVERLEY ROBINSON said he made it a rule to verify his diagnosis of pleurisy with effusion, whether septic or acute, by introducing the hypodermic needle. He had been astonished at times not to withdraw fluid with the syringe, while at other times he had obtained fluid where he had hardly expected it. He was, therefore, inclined to think that there must be sources of error in diagnosis which the text-books did not enable us to detect. At times he found the ordinary signs of pleurisy with effusion when no effusion was present. Then, on the other hand, he sometimes found marked thoracic vibrations with considerable effusion, instead of notable diminution of the vibrations, as stated in the text-books. Bulging of the intercostal spaces he had sometimes found present, sometimes he had not observed it. He had tried to follow up his studies, begun some years ago, to determine the character of the effusion, or its presence or absence, by the use of the stethoscope, but he had been unable to differentiate the cases by this means, and had arrived at the conclusion that there were only two signs which would enable one almost invariably to say that there was pleurisy with effusion in large amount. The first was absence of the respiratory sounds over a large area on the affected side, with flatness on percussion. Yet the presence of these signs in a case which he saw recently in consultation led him to make an erroneous diagnosis, the case proving one of rapid pulmonary congestion instead of pleurisy with effusion.

DR. ROOSEVELT thought the fact stated by Dr. Peabody, regarding the influence of fluid long present in the thoracic cavity in destroying the elasticity of the tissues, an important one in accounting for displacement of neighboring organs.

Gastro-Enterostomy for Pyloric Stenosis.—DR. DANA presented, in the absence of Dr. Weir, a man upon whom this gentleman had operated for stenosis of the pylorus, joining the stomach with the intestine below by means of rings of catgut. The patient had gained nine and a half pounds during the four weeks since the operation, and Dr. Dana and Dr. Bull both testified to his marked general improvement and relief from pain, from which he had previously suffered. He now took general hospital diet without any trouble.

The patient had suffered for about four years from symptoms of gastric ulcer and dilatation and pyloric stenosis. He had had great pain, frequent vomiting and constipation. Hydrochloric acid was found in the gastric juice. The diagnosis had been cicatricial pyloric stenosis from gastric ulcer.

Discussion upon the New Epidemic.—Dr. Dana read the following communication from Dr. F. P. Kinnicutt, who was confined to his house by an attack of the influenza:

"In bringing the subject of the present epidemic before the Society I have simply formulated certain propositions, which may serve as a basis for discussion.

"1. A specific, infectious disease is at present epidemic in New York and in a large portion of the United States.

"2. It is certainly identical with the epidemic, influenza, which at present prevails throughout Europe and Great Britain.

"3. The prevailing type of the disease in New York is characterized rather by the absence than the presence of an acute catarrh of the upper air-passages; at least in the onset of the affection.

"4. The disease, as seen in this city, is characterized by a sudden onset, with chills or chilly feeling, preceded at the most by a few hours of general malaise; by more or less frontal headache, not infrequently by nausea and vomiting; by general and severe muscular pains, the lumbar muscles being especially affected; by a rapid rise of temperature, the range in typical cases being between 101° and 105° F., with a pulse of proportionate frequency; the above symptoms accompanied by subjective sensations of great prostration and mental depression. The febrile movement is of short duration, the temperature, as a rule, regaining its normal range at the expiration of twenty-four hours; the muscular pains disappear rather later, the sense of prostration and mental depression continue for a variable length of time. The acute symptoms are very generally followed by a moderate catarrh of the larynx, and particularly of the trachea and larger bronchi.

"5. True relapses occur.

"6. Accompanying the existence of the epidemic there has been a marked increase in the prevalence of acute bronchitis and catarrhal and croupous pneumonia, an increase apparently not to be accounted for by the season of the year alone.

"7. The etiology of the disease is as yet involved in much obscurity. There are strong reasons for disbelieving in its contagiousness."

DR. PEABODY said his experience with the present epidemic had varied somewhat in one or two respects from Dr. Kinnicutt's. He believed no stress had been laid in the paper upon the fact that there was very commonly a great deal of depression going with it, both physical and mental. Some patients became so very blue and despondent that it was quite impossible to cheer them by the thought that they were going to be well in a few days. He had himself felt that way less than a week ago, yet he was able to attend this meeting.

Then it seemed to him not to have been as definitely marked in its points of attack as Dr. Kinnicutt had laid down. He had seen a number of people with all the prodromal symptoms which he had mentioned—the pains and aches, the headache—often nausea and vomiting in children; some would have merely a pharyngitis, and no affection of any other mucous tract at all. Some, after having prodromal symptoms, would have a tracheitis, which became a bronchitis, and if it were neglected this would be likely to become capillary. In hospital practice a number of patients who had had these prodromal symptoms went on to have pneumonia. It had seemed to him that there was not a definite entity, but that there was quite a variety of catarrhal lesions affecting different portions of the respiratory tract, and, in some cases, also the gastro-intestinal tract, and in different individuals with exactly the same prodromal or initial symptoms affecting subsequently different areas of those tracts. It did not seem to him that

it was as definite an entity as seemed to exist in Europe at the present time, but that there was great prevalence of quite a variety of catarrhal lesions and of other acute pulmonary affections. He had had during December more cases of pneumonia and acute pleurisy that ever before during the same month. And there was a greater number of cases of these two diseases in the New York Hospital than was ever known there before during December. There were twenty cases of croupous pneumonia alone at the present time. Regarding the prodromal and initial symptoms, he had had about the same experience which Dr. Kinnicutt had given. But when the disease became more fully pronounced his experience had not been quite as sharply defined.

Dr. Robinson did not recall a case of the so-called *grippe* among the children of the medical ward of St. Luke's Hospital, which was now under his charge. And in the women's ward, which was also under his care, there was not one case of pneumonia. He believed, also, that he had not had a case of acute pleurisy there during this epidemic. Several of the nurses had been attacked by the *grippe*, but only one had come under his immediate observation. According to her statement, she had had no catarrhal symptoms and no fever; but she was very much depressed mentally, and had aching in the bones and in the head, especially the back of the head. But he had been kept on a lively run attending cases in private practice, and must say that, so far as the laryngeal symptoms were concerned, they had impressed him as being spasmodic rather than catarrhal. Ordinary expectorant mixtures had not allayed the cough, nor had the cough been accompanied by catarrhal secretions, which one would expect to see in a catarrhal inflammatory condition of the larynx. He had succeeded in allaying the cough with chlorodyne more frequently than with anything else, and that, we knew, must have acted as an antispasmodic. Its administration might be preceded by that of ipecac or chloride of ammonia. The amount of pain in the limbs and general prostration varied in different individuals; in some being very slight, in others very considerable. There was nausea, sometimes an attack of vomiting, frequently chilly feelings in the beginning. The temperature varied a good deal. In some it scarcely rose at all; usually there was moderate elevation; in a few instances it went as high as 103° or 104° F.—higher than would have been expected in connection with the other symptoms. The affection lasted, as a rule, three or four days, but the patients afterward seemed to feel worse than he would have expected from an ordinary attack of catarrhal bronchitis of apparently like intensity. The community had received the impression that a solution of quinine snuffed up into the nostrils was a good remedy in this affection. Anything but a weak solution, however, was very irritating to the nose and larynx, and should not be used. When he was called to a case and found the patient with pains in the bones, he gave him spiritus mindererus. If there was anything of a bronchial attack he gave a large dose of carbonate of ammonium. This was eliminated through the respiratory passages and mucous membrane of the nose, and thus proved beneficial. He was convinced that no other remedy yet brought to the attention of the medical profession had greater control over a beginning coryza or attack of epidemic influenza. Nor could he see any possible objection to its use, as he could to the use of certain other drugs, like aconite and quinine. Aconite placed the patient in a condition to catch more cold; and large doses of quinine, if they aborted the attack, did so by depressing the heart's action and at the expense of the general system. While he did not believe there was any specific for the disease, yet he thought some remedies were more efficient than others. He had simply mentioned those which he had found most useful—carbonate of ammonium and chlorodyne.

Dr. Roosevelt said that in a number of cases which had come under his observation he had invariably found redness of the throat. This may have been a mere coincidence. The redness was usually confined to the anterior wall, spreading over the tonsils and anterior surface of the velum. It looked very much as if the parts had been touched with a paint-brush and red paint. It usually disappeared within twelve or twenty four hours. In those cases there had been no special catarrhal symptoms of the mucous membranes otherwise.

Dr. V. P. Gibney said that among one hundred and sixty children in the Nursery and Child's Hospital there had not yet been one case of the influenza. He had seen two or three cases in the house staff.

Dr. C. L. Dana's experience coincided almost exactly with Dr. Kinnicutt's. It seemed to him the term "influenza" was not quite appropriate, if by it was meant an infectious trouble in which the nasal passages were prominently involved. Probably half the cases seen by him had very little trouble with the nasal passages. The main symptoms had been fever, chilly sensations, prostration, and pains. His service at Bellevue Hospital last month had given him an experience very much like that of Dr. Peabody's in the New York Hospital. Five days ago there were about twenty-two cases of pneumonia in his ward alone, and during the month there had certainly been a much larger proportion of cases of pneumonia than they had ever before had in Bellevue Hospital.

Dr. Blanc, present by invitation, said he had had a mild form of the disease, and it had attacked the members of the family where he was staying. He himself was accustomed to have attacks of throat trouble, but this time it did not continue as long as usual, probably because it was of a different type.

Dr. Weir said it had not been seen in any of the patients in his wards at the New York Hospital, but he and the house staff had it.

Dr. Shrady said it had prevailed to a considerable extent at St. Francis' Hospital, compelling the postponement of operations for several days in a number of cases. He asked whether any of the gentlemen present had seen death result simply from this disease, and independent of its complications. A negative reply was inferred from their silence.

Dr. Robinson referred to the question of contagion, and expressed the view that the rapid spread of the epidemic could not be accounted for by its being carried by patients or letters.

Dr. Roosevelt said the same scepticism had been expressed in times past regarding the rapid spread of cholera, yet this was now known to be conveyed only by contagion.

The Chairman said this was too broad a subject for discussion on the present occasion.

Herpes Zoster in Children.—A French author states that he has seen twenty-two cases, within the last six years, of herpes zoster in children at the Villette Hospital, the ages of the patients in question varying from eight months to fifteen years. He summarizes his experience as follows: Herpes zoster is rare in children, one case per thousand being the mean ratio and of its occurrence, but it is scarcely less rare in adults. In the new-born infant it is seldom, if ever, seen. In the cases above referred to, fifteen occurred in female children. The left side was affected fifteen times in the twenty-two cases, and the right only seven. Herpes of the face and of the limbs is very uncommon. The disease mostly occurs in the months of May and August. In the majority of cases the herpetic attack is associated with digestive disorder, as dyspepsia, dilatation of the stomach, and enteritis. The disease in children is remarkably benign; it does not relapse nor cause troublesome complications. Its symptoms are transitory, superficial, and purely objective. In adults herpes zoster is often preceded, accompanied, or followed by pain of a neuralgic description; in children, on the other hand, it is absolutely painless when the age is under ten years. The treatment of infantile zona is purely local—some antiseptic covering is all that is necessary.—*Medical Press.*

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, February 6, 1890.

ALFRED L. LOOMIS, M.D., PRESIDENT, IN THE CHAIR.

Portrait of Dr. Hamilton.—Through the request of its officers the Academy was presented with an oil portrait of Dr. Frank H. Hamilton by the family of the deceased. A vote of thanks was extended the donors.

Discussion on the Prevailing Epidemic, Influenza.—Papers on different features of the epidemic were read by DRS. A. JACOBI (see p. 207), W. H. DRAPER, F. P. KINNICUTT (see p. 209), and RAMON GUITERAS (see p. 210).

Is it Influenza?—DR. F. H. BOSWORTH said he felt a little embarrassment in accepting the President's invitation to discuss this question, for his practice being devoted largely to the treatment of diseases of the air-passages at his office, he must admit that during the winter he had seen nothing which would justify him in the conclusion that we had had an epidemic of influenza. He did believe, however, that there was a general condition prevailing here which added something to colds to cause symptoms somewhat different from those attending ordinary acute tracheitis or rhinitis. A climatic condition had been prevailing which gave rise to what might be termed "break-bone fever," or a form of malarial poisoning, but the term "influenza" seemed scarcely warranted in describing this condition, if judgment were based on the appearance of cases seen in his office practice. The winter had been continuously warm and moist, and most favorable for malarial or "break-bone fever."

As it Affected Neurasthenics.—DR. M. ALLEN STARR said that forty-two per cent. of his patients with nervous diseases had suffered during the past six weeks from the epidemic. They showed many of the symptoms which had been described in the papers read during the evening; but his attention had been directed especially to two features of the nervous symptoms, namely, mental depression and peripheral functional nervous disturbances. Regarding mental depression, it had in many cases amounted almost to melancholia. Two neurasthenic patients confessed to a suicidal desire. Among the serious nervous symptoms it seemed to him this one of mental depression had been prominent. It had shown itself in a number of cases in connection with depression of the heart and alternating slow and fast pulse.

Peripheral Nervous Symptoms.—Among these he had seen a number of neuralgias—supra-orbital, facial, sciatic, ulnar, and musculo-spiral neuralgias. In only one case was there multiple neuritis, three or four nerves on the two sides showing decided neuritis.

It was known that in certain epidemics of infectious diseases there was increased frequency in development of chorea and acute antero polio-myelitis. There had not been an increase in the number of this class of patients at his clinic. The influenza had occurred in five of his patients with locomor ataxia. The pains of this disease were perceptibly worse during the attack of the influenza.

Independent of Climatic Conditions.—DR. JACOBI, replying to Dr. Bosworth, said it was true that such weather as we have had would predispose to catarrh. At times in the past it had been noticed that epidemics of catarrh had prevailed during mild winters. For instance, in 1789, according to Dr. Rush, there was a great deal of catarrh during January, February, and April, which were very mild months. But a large number of the epidemics, as history proved, had not taken place during such mild weather. In Europe, where the present epidemic had started, the winter had been cold. Then the dates of the outbreak of the disease at different places, commencing with St. Petersburg, October 12th, reaching Paris toward the end of November, Brussels the middle of December, and the United States about the end of December, pointed to its distribution by railroad and steamship travel.

DR. KINNICUTT also said that, while it was true the winter in the East had been unusually mild, yet the epidemic had reached Colorado and the West, where the winter was unusually severe.

Is Alcohol Prophylactic?—DR. KITCHEN inquired of the gentlemen what had been their experience with the use of alcohol.

DR. DRAPER said it was well known that alcohol had been largely recommended as a prophylactic against the influenza in Paris. He did not know what had been the result in this direction, but he did know that in patients who gave a history of alcoholism the disease or its complications had proved unusually fatal. He was inclined to think that alcohol, except in very moderate doses, was not prophylactic. He would rather say that by the reaction which followed its excessive use patients would be exposed to the disease who otherwise would escape it.

Its Analogy to other Infectious Fevers.—Dr. Draper had been struck by certain analogies existing between this and other infectious fevers, as cerebro-spinal meningitis and typhoid fever. Perhaps the lesions which were common between it and cerebro-spinal meningitis, such as affected the mucous areas, were in both instances due to the effect of the poison upon the vaso-motor system.

DR. BOSWORTH said: "In my own office practice, treating diseases of the air-passages, we would not have known that there was an epidemic of influenza in existence in New York. That is the only justification which I can offer for my remarks."

The Wicked Microbe not yet Found.—THE PRESIDENT said that during the past week he had observed that attacks of bronchitis had shown a strong tendency to go on and become capillary, and when the inflammation reached the cells next the pleura a pleurisy was likely to develop in that locality. Convalescence was not likely to be established for a period of two or three weeks, and during this time there was a general depression from which it was almost impossible to lift the patient. He had seen tuberculosis follow the capillary bronchitis in but two cases. The pneumonias were usually of the pleuro-pneumonia type. They had inoculated animals with all the varieties of bacilli which they had been able to find in cases of the influenza, but had not succeeded in producing the disease. Nor did he think success would attend such efforts, for the reason that animals seem to have immunity from the influenza.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE MECHANISM OF THE SUSPENSION TREATMENT IN LOCOMOTOR ATAXY—A UNIQUE CASE OF HERNIA—DEATHS OF SIR WILLIAM GULL, MR. JAMES ADAMS, AND DR. THOMPSON PYLE.

LONDON, February 1, 1890.

AT the last meeting of the Medical and Chirurgical Society a discussion took place on Dr. Cagney's paper on "The Mechanism of Suspension in Locomotor Ataxy," read at the preceding meeting of the society. Dr. George Ogilvie said he had performed many suspensions during the past year. He believed that during suspension the cord was relaxed in the dorsal region, and he thought this relaxation allowed the bundles of fibres to separate slightly and thus some adhesions were broken down; also, that this relaxation removed some impediment to the circulation, and so favored the absorption of any adhesions between the bundles of fibres. He did not think the method was of any use in the treatment of the ataxic state, but some of his patients, who were obliged to take morphine before the suspensions, were afterward able to do without it. He thought suspension from the neck was dangerous. Dr. Fletcher Little said he did not agree with Dr. Cagney that suspension from the chin and oc-

ciput was dangerous. Charcot had insisted that two-thirds of the weight must be suspended from the armpits, and only one-third from the head. If these directions were carried out, and the weight of the body very gradually permitted to fall on the head, there was little danger. If locomotor ataxy was a disease affecting the cerebro-spinal system generally, then extension from the armpits was insufficient to produce a beneficial result. Mr. Roughton asked on what grounds the column was said to be elongated during suspension? He did not believe such was the case. Describing his own sensations when suspended, he said that if he were a subject with tabes dorsalis, he should prefer to continue ataxic rather than be treated by the suspension method. Dr. Cagney then replied, and urged that if the cord were benefited by stretching, it was not benefited by relaxation, and *vice versa*. If the symptoms were relieved at all it was by relaxation, and he agreed with Dr. Ogilvie's explanation of the phenomenon. He contended that it was absolutely impossible to stretch the cord in the dorsal region, and no considerable stretching or relaxation was possible in the cervical region; the attempt to do so was unpleasant as well as useless, and he referred to some fatal cases which had been recorded. Professor Horsley had shown, some years ago, that it was not possible to stretch the spinal cord during life by any manipulation. Charcot declined to state that elongation of the cord would be beneficial to ataxic patients, though it was obvious, if his directions were followed, that this was the object aimed at. Dr. Cagney urged that if any benefit resulted from the suspension treatment it was from relaxation, and not from stretching of the cord. The danger and inconvenience of the method might, with care, be reduced to a minimum.

Mr. W. H. Bennett then related a very remarkable case of hernia. A laborer, aged fifty two, was admitted into St. George's Hospital, on October 26th, with symptoms of strangulation in a previously reducible, and apparently old-standing, scrotal hernia. Twenty-four hours before admission he felt burning pain in the scrotum and found the hernia down, though he had experienced none of the ordinary sensations warning him of a sudden descent of the gut. The rupture slowly increased in size, and all attempts at reduction failed. When seen by Mr. Bennett, six hours after admission, the right side of the scrotum was occupied by a pyriform swelling as large as two closed fists, which was clearly a strangulated hernia. Herniotomy was performed, and an oval fluctuating tumor exposed; this had not the appearance of peritoneum, and was suspected to be gut, though no peritoneal sac had been seen. As the hernia was irreducible, in spite of free division of the constricting soft parts, and as a hard mass of doubtful nature was perceptible inside the tumor, the latter was opened and a large quantity of clear fluid (such as often came from a hernial sac) escaped from it. The structure opened was found to be the cæcum, and, projecting into it through the ileo-cæcal valve, was an invaginated piece of gut three inches long. The cæcum was quite free from peritoneal covering, but behind it, and adherent to the testicle, was a piece of omentum lying in a peritoneal sac, which had, presumably, also contained the reducible hernia described by the patient. All attempts to reduce either the intussusception or the hernia failed, and a temporary artificial anus was therefore made, the condition of the patient being too critical to permit of abdominal section being performed. The patient failed to rally, but died from asthenia on the third day. Mr. Bennett remarked on the extreme rarity of extra-peritoneal hernia of the cæcum, and on the small percentage of cases of strangulated hernia of all kinds in which the cæcum was found in the sac.

Mr. Treves opened the discussion on the case, and remarked that the case was unique. The statement that "a hernia of the cæcum had no sac" still existed in many text-books. He had traced it back and found that Scarpa was responsible for its origin. He had himself collected fifteen cases of hernia of the cæcum; in thirteen of these there was a complete sac, and in two so little sac as almost to justify the statement that there was none. He had obtained permission to examine a specimen in St. Bartholomew's Hospital museum, which was described in the catalogue as one of hernia of the cæcum without a sac, and found that there was no cæcum, but that the hernia was of the sigmoid flexure, and that there was a complete sac. He questioned whether Mr. Bennett was right in describing the case as strangulated. These cæcal herniæ were often incarcerated and inflamed. Moreover, the patient walked into the hospital, an unusual proceeding in a patient with a strangulated rupture, though not uncommon with an incarcerated hernia. The association of the intussusception with the hernia was interesting. The presence of the clear watery fluid was explained by the acuteness of the ileo-colic form of intussusception, and was due to early œdema of the convex side of the intussusception, so that fluid would escape directly the bowel wall was incised. Mr. Hulke referred to the popular belief that a herniated cæcum had no sac, and allowed that cases with this condition were rarely met with. Mr. Barwell remarked on the frequency with which intussusception and hernia were associated. Mr. Bennett then replied. He considered the hernia was strangulated, not so much from the actual symptoms, though the man had been vomiting for twelve hours, as from the fact that after opening the cæcum he could not pass his finger up the colon on account of the constriction. The patient's being able to walk into the hospital did not negative strangulation, for he had recently operated on a man who walked into the hospital, and who had fæces in the sac of a strangulated hernia; the rent was sewn up with a Lembert suture and the patient recovered. He accepted Mr. Treves' account of the origin of the watery fluid.

By the death of Sir William Gull—which occurred on Wednesday last—British medicine loses one of its most representative men and most worthy exponents. Even his enemies—and, unfortunately, he made several of late years—must admit that Sir William Gull stood in the first rank as a scientific physician and clinical teacher. Originally connected with Guy's Hospital in some humble lay capacity, he afterward entered there as a medical student, and soon distinguished himself. He graduated with honors at the University of London. In 1848 he was elected a Fellow of the Royal College of Physicians, and in 1851 (being then thirty-five years of age) was appointed Assistant Physician to Guy's Hospital. His rise to fame and wealth was rapid. His numerous papers on scientific medicine in various branches, combined with his skill as a clinical teacher, soon gained him a great reputation, and his success in private practice was phenomenal, being, indeed, only rivalled by that of Sir Andrew Clark some years later. His attendance on the Prince of Wales, during the latter's serious attack of typhoid fever in 1871, was the means of bringing Gull (then only Dr. Gull) still more prominently before the public. He was created a baronet on the Prince's recovery, and also appointed one of the physicians in-ordinary to the Prince of Wales, and one of the physicians extraordinary to the Queen. On two memorable occasions Sir William Gull incurred considerable professional odium by his conduct toward other practitioners, and on one occasion a colleague brought his conduct before the Censors Board of the College of Physicians. In spite, however, of these incidents, Sir William Gull's popularity as a physician continued, and he still had more patients than he could see until his retirement from practice two years ago, in consequence of illness. But for his health, there can be little doubt that he would have been run as a candidate for the presidency of the College of Physicians at the last vacancy. In spite of his failings, there will be but few who will not acknowledge that his death leaves a gap not easily filled.

I have also to record the death of Mr. James Adams and of Dr. Pyle. The former died at the comparatively

early age of forty-five. He was formerly surgeon to the London Hospital (as was his father before him, who was familiarly known as "Jack" Adams), and attained distinction not only in general surgery but in ophthalmology. He was perhaps the most skilful operator on the staff of a hospital long renowned for its surgeons. While, however, success in his profession seemed just within his grasp, he was attacked with an ocular affection which soon caused irrevocable blindness in both eyes. He retired from practice in consequence of this affliction. Lately he suffered from cerebral symptoms, and died from coma on Sunday last.

I must also briefly chronicle the decease of Dr. Thompson Pyle, who practised for many years as a physician in Sunderland. He was a member of the Senate of the University of Durham, and for five years its representative on the General Medical Council.

MASSAGE, MARRIAGE OR, WHAT?

To the Editor of the Medical Record

Sir: A woman wants to protest against the importance attached to congestion of the mammary gland by Dr. Fowler, in a recent issue of your paper. Of course a woman has congested milk-glands, and, of course, she has a congested uterus and ovaries at times, and, of course, these several congestions can be relieved by menstruation, for instance, and in other ways. To assume that orgasm will dissipate these congestions, there is surely nothing new about that. To artificially induce orgasm for their relief is, however, playing with fire. Can you imagine that the cure will be permanent in the case of any of the hysterical girls to whom the doctor has referred? And if not, what then? Must the doctor be called in again and again for the relief of the mysterious symptoms? And must the girl degenerate into that most despicable creature—the woman who cannot live without her physician? A sentiment of respect, even in Dr. Fowler's mind, must follow the girl who would not have her "lump" treated.

So long as pelvic massage was confined to cases of pathological alterations in structure and function, we listened in patience, but when it comes to be applied for the relief of a physiological congestion, and applied to innocent, ignorant young girls, it is time to call for a halt. The practice then assumes a plane not perceptibly different from that of the masseuse who cures nervous disorders in men by similar means.

If you asked me what do women do with these cases, I would tell you that we first explain to the girl herself the character of her ailment. We disabuse her mind of the idea that there is anything wrong or immoral about the condition, but tell her that, on the contrary, it is a normal expression of her womanhood. We tell her further that it is a temporary condition; that, at the worst, it will pass over in a little time, and we tell her of various means by which it may be dissipated or avoided. One of these is physical exercise. An exhaustive gymnastic course might be prescribed. The Swedish movements for the relief of pelvic congestion are worth some study in this connection. Mental work is another great prophylactic against undue sexual irritability. Let her enter some competitive examination, take lectures at the Barnard, or some special course of instruction Cheerful companionship should be in all this insisted upon. Among working-girls persistent eroticism is so rare as to almost invariably indicate an unsound mind, which is, of course, the ordinary tendency of these cases.

The question of women physicians in asylums follows this same line of argument. The demented woman is highly erotic as a rule. To supply women for her immediate attendants is simply to diminish the disturbing influences likely to increase her mental instability. The necessity is not for a woman's attentions for gynecological treatment alone, but for all that presupposes close proximity in these cases. Wishing that men and women could understand each other a little better,

I am, respectfully yours, X.

FORCED RESPIRATION.

To the Editor of the Medical Record.

Sir: I have read with interest Dr. Vanderburg's article on "Forced Respiration," in your number of February 8th.

In my last two cases reported to the New York State Medical Association, and published in its "Transactions," it was demonstrated that forced respiration could be kept up through a mask covering the mouth and nose.

The last patient whose life I saved owes it to the application of air throught the buccal cavity. Tracheotomy was afterward performed, as it was evident that the respiration would have to be kept up for some considerable time. It was after eleven and one-half hours of forced respiration that the patient could be left to breathe for himself. Two ounces of laudanum had been taken and all retained.

As the doctor hints. the evolution of forced respiration since my first operation, the saving of five human lives which would have been sacrificed without it, means almost a revolution in our methods of artificial respiration.

To the apparatus which I originally devised and have used in operations, I had a rubber mask supplied before being aware of the work of Dr. Vanderburg. It is thus applicable to the operation with or without tracheotomy. This I am inclined to consider important, as I believe cases may be saved with tracheotomy which would be lost without it. Time alone will determine this positively. Up to the present time, counting the two cases reported by Dr. Vanderburg, eight lives have been saved. The operation has come to stay, and it has promise of a great future. George E. Fell, M.D.

Buffalo, N. Y., February 13, 1890.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from February 9 to February 15, 1890.

Taylor, B. D., Captain and Assistant Surgeon. Leave of absence is granted for fifteen days, to take effect on the 15th proximo. S. O. 17, par. 2, Headquarters Department of the Missouri, February 7, 1890.

Alexander, Charles, Lieutenant-Colonel and Surgeon. By direction of the Secretary of War is relieved from duty as examiner of recruits in New York City, and will report to the commanding general, Division of the Atlantic. for duty as attending surgeon in that city. Par. 1, S. O. 33, A. G. O., Washington, February 8, 1890.

McElderoy, Henry, Major and Surgeon. By direction of the Secretary of War is relieved from duty at Fort Wayne, Mich., and will report to the Superintendent of the U. S. Military Academy, West Point, N. Y., for duty as post surgeon, relieving Major Henry R. Tilton, Surgeon, who, after being thus relieved, will report in person to the commanding officer, Fort Wayne, Mich., for duty at that station. Par. 13, S. O. 33, A. G. O., Washington, February 8, 1890.

Loring, Leonard Y., Major and Surgeon. By direction of the Secretary of War the extension of leave of absence, on surgeon's certificate of disability, granted in S. O. 268, November 16, 1889, from this office, is still further extended two months on surgeon's certificate of disability. Par. 7, S. O. 34, A. G. O., Washington, February 10, 1890.

Tilton, Henry R., Major and Surgeon. By direction of the Secretary of War, leave of absence for two months is granted, to take effect upon his being relieved from duty at the U. S. States Military Academy, West Point, N. Y. Par. 6, S. O. 34, A. G. O., Washington, D. C., February 10, 1890.

SMITH, ANDREW K., Colonel and Surgeon. By direction of the Secretary of War the retirement from active service, on February 9, 1890, by operation of law, under the provisions of the act of Congress, approved June 30, 1882, is announced. Colonel Smith will proceed to his home. Par. 5, S. O. 34, A. G. O., Washington, D. C., February 10, 1890.

CRAMPTON, LOUIS W., Captain and Assistant Surgeon. By direction of the President is detailed as a member of the Army Retiring Board at Chicago, Ill., convened by War Department order, dated November 18, 1889, published in S. O. 269, November 18, 1889, from Headquarters of the Army, *vice* Major Henry McElderoy, hereby relieved. Par. 9, S. O. 36, A. G. O., February 12, 1890.

SMITH, G. A., Lieutenant-Colonel and Surgeon. Leave of absence is granted for twenty days, to take effect about February 10th. S. O. 15, par. 4, Headquarters Department of Arizona, February 8, 1890.

Official List of Changes in the Medical Corps of the United States Navy for the week ending February 15, 1890.

BATES, N. L., Medical Director. Ordered to Naval Hospital, Mare Island, Cal.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending February 15, 1890.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	19	6
Scarlet fever	72	11
Cerebro-spinal meningitis	0	0
Measles	77	6
Diphtheria	103	30
Small-pox	0	0
Varicella	7	0
Cholera	0	0

Indiscriminate Sales of Poisons.—At a meeting of the Trade Association of Philadelphia Druggists, February 10th, a discussion of the sale of articles of a poisonous character was introduced by E. T. Ellis. There was a general expression of opinion condemning the indiscriminate sales of all such drugs, but it was said that the sentiment of many druggists outside of the Association was different. The State Pharmacy Act, it was said, provides that an article sold without a prescription must be safe in sixty-grain doses, but during the late epidemic antipyrine was sold almost as freely as quinine. Dr. Jamison suggested that a large number of deaths might have been caused by the free use of this drug from its heart-depressing qualities. The secretary, W. L. Turner, said he would not sell "Rough on Rats," an article nearly pure arsenic, without registering the purchaser.

Society of the Alumni of Charity Hospital.—At the meeting of the Society of the Alumni of Charity Hospital, held at Clark's on the evening of February 11th, Dr. R. W. Taylor read a paper, "History of a Case of Syphilis Fourteen Years after the Onset of Cerebral Symptoms, with Remarks on Subacute Specific Meningitis and its Treatment;" presentation of the case. Dr. W. L. Baner read a paper entitled "A Contribution to the Question of Inhalation." The discussion of both papers was animated, and was participated in by Drs. Beverley Robinson, D. Bryson Delavan, J. B. Bissell, W. L. Carr, George Thomas Jackson, and others.

A Novel Case of Maternal Impression.—Dr. W. J. Middleton, of Steelton, Pa., writes: "Apropos of the frequent mention of the matter of maternal impressions in your journal, let me report a case. "Mrs. R——, aged twenty-four, married a year and a half, was delivered of her first child, a son, November 20, 1889. Labor natural, child well formed in every respect, except that the foreskin of his penis lies in redundant folds, retracted upon and behind the corona glandis, leaving the glans exposed in all but its upper one-fifth. The mucous surface shortened to the said upper one-fifth is neither too tight nor adherent, but is easily retracted so as to uncover the balance of the glans. The foreskin is sufficient to cover the whole glans when pulled down, but let go, at once retracts. The husband, R——, consulted me June 17th, and at various times to July 15th, for an obstinate herpes præputialis, which worried him very much. Wife says that she several times observed him with retracted foreskin dressing his penis, and shared in his anxiety. She was then between four and five months gone."

More about Bromine in Diphtheria.—Dr. E. T. Strong, of Elizabethtown, N. Y., writes: "Dr. Middleton Goldsmith published an article in a Rutland, Vt., paper, in 1879, advising the use of bromine as a preventive of diphtheria, stating that there would be no new case of diphtheria where it was used as he directed. He directed that a solution be made in water, with the aid of potassium bromide, and a little put in a saucer of water and renewed often enough to keep the room smelling of it. Believing that any statement of the kind by him was worth considering, I tried it, and have used it ever since, in addition to the treatment advocated by Dr. Billington in the RECORD a few years ago. My cases have been neither numerous nor severe enough to make a thorough test; but, so far, my experience confirms Dr. Goldsmith's assertion, that no new case would develop where the bromine was used. In the last case I attended before using bromine, all the children of the two families in the house were attacked. In one of my latest the infection was brought from a relative's, where all the children died; but although in this case the other children were in the room with the patient, no one took the disease. I have used it in typhoid, scarlatina, bowel troubles, and other diseases, with gratifying success. I have thought that it had a favorable effect on the course of the disease. In Dr. Howard's case of thapsia poisoning (RECORD of January 25th) it is evident that the thapsia was left on too long. I direct the patients to apply the plaster on retiring, and to remove it in the morning, cautioning them that if left longer it will cause severe discomfort. I should expect severe symptoms from a good plaster left on twenty-four hours, in a susceptible patient."

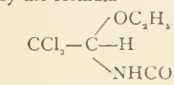
Consultants and Consultations.—In the course of a recent address, Dr. T. C. Allbutt makes the following remarks on this subject (*The British Medical Journal*): "You will find that, both in respect of competition and of consultation, the elements of mistrust are not inactive. The temptation to score off another man's openings seems to some persons irresistible, in spite of the certain turn of the wheel against themselves another day. Perhaps they hope to win on the average. How mean it is! How mean even between rivals! But for a consultant to act thus by word, or even by look or gesture, is cowardly and base indeed. At the moment the consultant has enormous power, and should therefore err on the side of generosity, especially in the absence of his brother practitioner. And yet who does not know the raised eyebrow, the shrug, the 'I-could-an-I-would' air of the fashionable consultant, as he listens condescendingly to the patient's report of his own doctor's opinions. *Salus ægrotantis suprema lex*, the patient's safety is before all else; that must be clearly posited; but his safety rarely comes even into pretence. The occasions are very rare in which the safety of the patient involves a breach of consent between his doctors. In my experience a family attendant is always very glad to try any plan of treatment which seems reasonable, and it is the duty of the consult-

ant, where treatment is manifestly changed, to speak of the change, not as dictated by himself, but as the result of a joint consultation. In most cases he can truthfully add that a change would not have been made unless the previous treatment had been well tried in vain. Changes of diagnosis, except in case of grave error, can usually be developed gradually, so that sudden declarations of change of opinion are avoided. But the public may say, Is this reticence fair to us? Certainly, if the patient's interests be safeguarded—that is, if the doctor in charge be not an ignorant fool or a shifty knave, and in these cases the consultant must, by letter or visit, keep a sharp eye on the progress of the case—the reticence is not only harmless to the patient, but of the greatest value to him. Nothing does a sick man more harm than to have his confidence shaken in his doctor, and to chop horses in midstream is rarely desirable. Even where a difference between two medical men is irreconcilable—and such cases have occurred to me from time to time—the difference can be amicably arranged. In thirty years I never had to supplant my brother on this account. The family doctor must be charged with the duty of setting forth the difference to some sensible friend of the patient, and in my experience this has always been done most conscientiously. Such cases are usually obscure and difficult, and it becomes the consultant in his turn to point this out, and to express a willingness to call in a third physician to aid in the decision. If all parties are straight and unselfish, these difficulties are readily adjusted. Indeed, with seasoned practitioners, consultations are always smooth, and nearly always welcome on both sides. It is you, touchy young men, just out of the schools, who give us the trouble—who bridle up at the suggestion of a consultation, and declare that nothing more can be done. An older man knows that a good talk over a case is, at any rate, a pleasant meeting, and probably valuable to him at least in bringing about an orderly revision of the symptoms and in refreshing the confidence of his patient. He knows, too, that when a doctor is sick himself, he calls out for a consultation sooner than a layman does, and runs from one doctor to another in defiance of all convention. I never knew a sick doctor who failed to consult at least three London physicians in a forenoon, usually concealing from each his visit to the others. The fact is life is dear not to doctors only; to me it is marvellous, not that patients slip off to consultants, but that, with the fear of death before them, they are so loyal to their own advisers. Always, then, welcome consultations. Anticipate, if possible, the patient's wishes in the matter, or, at any rate, the wishes of his friends. Never repeat the silly boast, 'My patient has such confidence in me he does not want a consultation.' I used in secret to hear rather too often the other side of that story, and if the patient should not want it you ought to want it. The public is right in regarding a consultation as at least a tribute to the sacredness of human life, and it keeps doctors up to the mark."

A Museum for the Illustration of Human Passion.—A new departure in museums is announced from Florence, where a "Psychological Museum," for the collection and display of "all documents serving to illustrate human passions," has been established by ministerial decree. Professor Mantegazza is to be the director of the new institution, and courses of instruction are to be given there on "experimental psychology."

Pyocyanine.—This name has been given to a crystallizable chemical compound of organic origin, first isolated by Fordos. It is the leucomaine furnished by a special variety of micro-organism, the *bacillus pyocyanicus*, one effect of its presence in pus being to give a peculiar and characteristic blue color. This bacillus is not productive of ill effects in man, but, curiously enough, it is promptly fatal to the rabbit. The pyocyanic malady is thus an ideal one for purposes of study, furnishing, as it does, an organism easy to cultivate, an animal in which it gives rise to a well-marked group of symptoms, and a chemical compound produced by the organism which can be isolated and acts upon the animal. It was after long and painstaking researches in this direction that M. Charrin was led to suggest that the pathogenic effect of microbes is primarily due to the poisonous substances excreted by them, and further, that these soluble poisons were, under certain circumstances, the best prophylactic for the disease to which the particular bacillus gives rise. Immunity from a specific disease may thus be conferred in at least two ways—1, by introducing into the tissues an attenuated microbe, or, 2, by introducing a certain proportion of the diluted soluble toxic agent secreted by them. The fact that it is possible to confer a degree of immunity independently of the bacillus itself, disposes of the general application of the phagocytosis theory promulgated by Metchnikoff, in virtue of which the leucocytes of one tissue were supposed to become trained, as it were, to the battle against the invading host on the principle of the well-known all-round antidote of Mithridates. As M. Charrin points out in his monograph on the subject, this immunity is due rather to increased powers of resistance to the influence of toxic agents. This useful bacillus has also enabled Messrs. Bouchard and Charrin to carry out some very instructive investigations into what is known as "mixed infection," and they have succeeded in demonstrating that the combined effects of the injection of more than one variety of pathogenic micro-organisms are lessened in proportion to the secretion by the bacillus of substances prejudicial to the bacterium and the exhaustion of the pabulum by the bacillus at the expense of the bacterium. The attentive study of this one bacillus has opened up possibilities in the embryonic science of bacterio-therapy which subsequent researches will in all probability show to be possessed of an importance in the prophylaxy of disease that the scientific mind cannot compass, and can at present only foreshadow.—*The Medical Press.*

Somnal.—The last new hypnotic has been named "somnal" by Radlauer (*Journal de Médecine*, October 20, 1889). It has a formula of $C_7H_{16}Cl_2O_2N$, and is a mixture of alcohol, chloral, and urethan. It has been used in doses of thirty grains, in the form of a solution, sweetened with syrup. It is claimed to exercise no unfavorable action upon the pulse, respiration, or temperature, and by the author is stated to possess the properties of chloral and urethan without possessing their after-effects. It is stated to be unaltered by acids or silver nitrate. It has been claimed by Lutze (*Pharmaceutische Zeitung*, October 26, 1889) that the term "ethylized chloral-urethan" is simply a blind, and that the so-called new product is nothing more than chloral-urethan, or ural, under a new name. This statement has, however, evoked a denial from Radlauer (*Pharm. Journ and Trans.*, November 2, 1889), who affirms that "somnal" is a product of the direct combination of chloral alcoholate and urethan in a vacuum apparatus, and that its composition is correctly represented by the formula—



As to whether it is any better than the other hypnotics remains to be seen.—*The Therapeutic Gazette.*

The Increase of Venereal Disease in Italy.—In view of the spread of venereal disease in Italy since the repeal of the regulations formerly in force, the Minister of the Interior has appointed a commission to investigate the subject, and suggest measures for the repression of prostitution and syphilis.

The Use of Salol in Producing Antisepsis of the Urinary Passages.—At a recent meeting of the Société Médicale des Hôpitaux, M. Dreyfous discussed the question of rendering the urinary passages antiseptic by means of

internal medication, instancing the good effects he had obtained from the use of salol in many cases of blennorrhœa. Salol, or salicylate of phenol, when it comes in contact with the pancreatic juice, is separated into carbolic acid and salicylic acid, both of which are eliminated by the kidneys, the first as phenyl-sulphate of soda, and the second without change. These facts have been established by Nencki, Lepine, and Sahli. By administering salol, therefore, we may produce a stream of aseptic urine, which washes the mucous lining of the kidneys, bladder, and urethra, thus establishing the antisepsis of these surfaces much more thoroughly than can be done by the use of injections from without. Sahli has shown that the urine of persons who are taking salol is antiseptic, and also that the salol is well borne, even in large doses. This remedy would seem to fulfil all the conditions that Bouchard, in his studies of the therapeutics of infectious diseases, has put down as necessary for the antisepsis of this special series of organs. It has the advantage of being only slightly soluble, and so non-toxic; it is not a general antiseptic, an antithermic, or intestinal antiseptic, but seems to reserve its action for the urinary passages, and its adaptability for this special end is comparable with the action of naphthol in intestinal antisepsis. M. Dreyfous has administered the salol, alone or in combination with balsams, in seven cases of blennorrhagia, the dose varying from five to eight grains. The discharge increased rapidly in each instance, and in one case which had lasted for four days the cure was complete in three days. The good results seem to be attributable to the fact that the salol renders the urine aseptic, and probably antiseptic. Certain cases, in which the salol was administered alone, proved that the good result was due to it, and not to the balsams, although the speaker preferred to give it with copaiba or cubebs, in order to hasten the cure. If this effect of the drug shall be well established, it will commend itself to the surgeon in those cases where it is desired to render the urine aseptic before an operation upon the genito-urinary tract. In reply to M. Chantemesse, who asked to which of the products of the decomposition of salol the antiseptic action was attributable, M. Dreyfous said that the antiseptic power of phenyl-sulphate of soda, that being the form in which the phenic acid is eliminated, is not yet proven, while we know that the other product, the salicylic acid, is certainly antiseptic. The latter would cause serious disturbance of the digestive tract if administered in quantities as large as can be obtained after the ingestion of salol.—*The American Journal of the Medical Sciences*, February, 1890.

On Guard for Typhus Fever.—Nine cases of typhus fever have occurred in this city since December 24, 1889. All but two received the contagium of the disease abroad. Two developed it from contagium received from infected material brought to this city from Antwerp. While the Health Department of the City of New York believes that it has all persons who have been in contact with the cases that have occurred here under observation, it nevertheless behooves physicians practising among the class of people with whom emigrants are likely to be found, to be on their guard against typhus fever.

Cholecystenterostomy.—At a recent meeting of the Royal Medical and Chirurgical Society Mr. Mayo Robson, of Leeds, communicated a paper on a case of this kind occurring in a woman who had been operated on by abdominal section for right pyosalpinx in 1887 (*Medical Press*). Nine months later, the patient having meantime enjoyed good health, acute peritonitis set in, and laparotomy was resorted to for evacuation of pus accumulated in the gall-bladder. The latter viscus was stitched to the side, a biliary fistula remaining, from which, during seventeen months, bile constantly escaped, rendering existence a misery. At the end of this time the abdomen was opened through the old laparotomy cicatrix, and the gall-bladder fixed to the hepatic flexure of the colon by a double row of chromicized sutures, free communication between the two viscera being established, and the old biliary fistula closed. Healing by granulation ensued, and after a few weeks the motions became normal.

The Mydriatic Alkaloids.—Merck's recent researches on the solanaceous alkaloids tend rather to show a wider difference between their chemical and physiological properties than has hitherto been believed to exist. It is a well-determined fact that atropine not only frequently gives rise to a severe conjunctivitis, but also quite suddenly a severe toxic effect follows its use. Duboisine and daturine act much like atropine, even more energetically, but on the whole are less liable to induce unpleasant symptoms. Hyoscyamine more closely resembles atropine in its action, although it is less toxic; but it is a decided hypnotic when administered in minute doses. On the other hand, hyoscine induces atropine effects, and is more rapid in its action, but its administration is not attended by the toxic symptoms of atropine, and it is hypnotic. Homatropine paralyzes accommodation as atropine does, but its effects are of much shorter duration, which is a decided advantage in many respects.—*Medical Press.*

Rupture of Uterus—Extraction of Fœtus Six Weeks Later.—Dr. St. Braun, of Cracow, describes the following case: A woman, thirty-eight years of age, the mother of nine children, the youngest three years old, became pregnant. The fœtal movements ceased for six weeks, and for two weeks before admission into hospital fetid pus discharged from the vagina and umbilicus. There was much debility, but no collapse nor hemorrhage. A weight seemed to roll about in the abdomen when the patient moved. Diagnosis was very difficult; circumscribed peritonitis, or extra-uterine pregnancy with suppuration of the sac and discharge through the navel and vagina was suspected. Abdominal section was performed, and a well-developed, macerated fœtus, covered with pus, was discovered free in the peritoneal cavity. The patient lived some time, but ultimately sank from exhaustion. Spontaneous rupture of the uterus had taken place from some unknown cause during the second half of pregnancy. The fœtus had escaped into the peritoneal cavity, died, and set up suppurative peritonitis. At the necropsy it was found that one intra-peritoneal abscess had burst through the umbilicus, the other had entered the fœtal membranes, caused suppuration of the placenta and discharge of pus into the cervix and vagina. The bladder and renal pelves had become inflamed. The latter complication is in itself sufficient to account for death. Had it not occurred, the recovery of the patient would have been highly probable.—*The British Medical Journal.*

Anthrax Cured by Subcutaneous Injection of Corrosive Sublimate.—A large malignant pustule was situated on the back of the hand of a man who had been engaged in removing the hides of cows, having a superficial graze on the back of his hand. The index-finger was of double its normal size; two extensive vesicles, filled with dark serum, included the dorsal aspect of the first and second phalanx; lymphatic inflammation extended from the hand up the forearm on the radial side. Six subcutaneous injections, with a four-thousandth solution of sublimate, with the view of forming a protection against the encroachment of the bacteria. It was not without some resistance on the part of the patient, in consequence of the intensity of the pain occasioned by them, that these injections were repeated during eight days. Besides the injections the hand was kept in a warm bath of sublimate solution during the daytime, and at night was covered with a cataplasm of chopped walnut leaves, moistened with the sublimate solution. This treatment was continued for six days longer, and terminated in cure of the gangrene. Cicatrization was complete in fifteen days.—*L'Union Médicale.*

RUPTURE OF THE BLADDER: A CASE WITH MISTAKE IN DIAGNOSIS.

BY JOSEPH D. BRYANT, M.D.,

NEW YORK.

BELIEVING that errors of judgment, though they be the results of careful consideration, and also that illy-considered conclusions, hastily formed, teach us more than our successes, I will present to your attention the narrative of a case which was to me most interesting and instructive, and leave it for you to decide to which of the two classes just mentioned it more properly belongs.

A. D——, aged twenty-nine, cart driver, temperate, admitted to Bellevue Hospital, April 12, 1887. Thirty-six hours before admission, the patient fell from a cart loaded with coals (while in motion) which he was driving. He fell in front of the left wheel of the cart, which came in contact with the outer surface of the crest of the left ilium while he was lying on the street, and his body was pushed along the paved street in front of the wheel, so he persistently maintained. At all events, he was sure that the wheel did not pass onto or across any part of the pelvis. The patient had never sustained an injury before of any part of the body, nor had he suffered from any previous illness. He had never had any form of venereal disease. All of the functions of the body had previously been performed with unvarying perfection, so far as he could judge. He was positive that he had emptied his bladder completely and without difficulty an hour and a half before the fall. He said that he had passed no urine for thirty-six hours before admission, and that one or two ineffectual attempts to draw it had been made during that time.

On Admission: General physical condition good; abdomen much distended in the hypogastric and lower part of the umbilical regions; no general tympanites; pain and tenderness on moderate pressure in the hypogastric region; temperature (buccal) 98½°; respiration and pulse presented nothing unusual; no nausea or vomiting; no evidence of infiltration of any part of the abdominal walls or perineum. The patient made no complaint except of distention; said he felt well otherwise. When examined he was lying on the back, with the lower limbs extended and placed parallel with each other. At the outer surface of the left ilium, there was an extensive and deep ecchymosis, which extended upward nearly to the last rib, and forward on the abdomen about two or three inches in front of the anterior superior spine of the ilium. The ecchymosis had been caused by the force of the cart-wheel, so the patient said. He thought so because the wheel "hit" him in this situation.

The pelvic bones were not broken, nor were their connections loosened. Immediately after admission, Dr. Houghton, the house surgeon, drew off about two ounces of high-colored urine with a medium-sized gum catheter. He experienced no difficulty with the introduction of the instrument. As soon as I arrived at the hospital the patient was placed at once on the operating-table, and the necessary arrangements made to secure a more careful examination; this to be followed by a laparotomy, if rupture of the bladder were thought to have taken place, as suspected by Dr. Wallace, the physician who sent him to the hospital. The prominence of the median line of the abdomen had an oval outline, and was dull on percussion, even up to the umbilicus. Tympanitic resonance was well marked at either side of the prominence down to the brim of the pelvic cavity. Thinking the case to be one of retention of urine only, I introduced a catheter at once, without further inquiry or examination of the patient. About two ounces of a highly-colored and apparently blood-stained urine were withdrawn. This amount of urine flowed freely from the instrument until suddenly checked, apparently by an obstacle in the eye of the catheter, and on withdrawal of the instrument a small clot was found in the eye, as was suspected. The clot was removed, and the instrument at once reintroduced without difficulty, and about the same amount of fluid escaped as before, and was then followed by manifestations similar in all respects with those following the previous act.

Four ounces of warm Thiersch's fluid were then injected through the catheter, principally for the purpose of cleaning the eye of the instrument, but incidentally to test the integrity of the bladder. Immediately following the injection of the fluid, sixty-three ounces of high-colored, faintly bloody fluid flowed continuously from the catheter without difficulty. The expulsive force, however, was not vigorous, and toward the last the flow was accelerated by manual pressure on the hypogastrium. After about thirty ounces of this fluid had escaped, and while considering whether or not I would withdraw the entire amount at once, I remarked to the members of the house staff: "This urine is flowing either from an over-distended bladder, complicated with injury of the right kidney, or I have passed the catheter through an opening in a ruptured and collapsed bladder, and am withdrawing the fluid from the peritoneal cavity." I said further, in almost the same breath: "Had I been thoughtful enough to have made a rectal examination to ascertain if the bladder were distended before having passed the catheter at all, no doubt could now exist as to these points." I concluded to withdraw the entire amount, even at the risk of causing a greater subsequent disability of the bladder than if some portion had been permitted to remain. After the withdrawal, the patient said he "felt first rate," "suffered no pain or discomfort." The entire hypogastric region had become tympanitic on percussion, and the hypogastric distention was gone. Deep pressure did not cause pain, and unusual tenderness was not complained of in this region. Still I was not satisfied. Fifteen ounces of warm Thiersch's fluid were then injected to test the integrity of the bladder wall, and fourteen and a half ounces were withdrawn at once, followed by some dribbling, which was estimated by the lookers-on as equalling in amount the remaining half-ounce of the injected fluid. Finally, one pint of this fluid was injected, with the view of studying the effects on the hypogastric region, and on the base of the bladder, to be determined by rectal examination with the finger and by abdominal percussion. As the fluid was injected the gradual hypogastric distention was noticed by all present, and at my request, Dr. Clark, a house surgeon of the hospital, watched the effect of the injection on the abdominal outline. Percussion, palpation, and inspection alike gave evidence, after the injection, of an enlargement resembling in all respects moderate distention of the bladder. On rectal examination with the finger, the base of the bladder could be easily outlined, although the wall of the organ in this situation was not tense, nor did I think it would be on ac-

count of the previous over-distention of it, that was thought had taken place. All but two ounces of the pint of fluid were then drawn away; half an ounce was estimated for dribbling as before, and the remaining ounce and a half, it was thought, might have remained in the bladder, due to the loss of the contractile power of the organ. I was not at all satisfied with this amount of shortage, as it seemed to me that with supra-pubic pressure as before, all but half an ounce at least ought to be expelled. I suggested the advisability of an exploratory incision, and even directed the giving an anæsthetic for the purpose, but the patient did not concur, and in my judgment there was not sufficient evidence of rupture to warrant the urging of this measure. The patient wished to "wait and see," as he expressed it. I then entertained, for a moment only, the propriety of the introduction into the bladder of sixty-three ounces of fluid, in order to study the effects on the bladder of this amount of fluid. In other words, to begin over again. However, the fluid at hand was nearly gone, and the proposition was considered unwise in any aspect of the case. At this time, too, I was still inclined to the belief that the patient had suffered from retention of urine, due to shock from the previous injury, causing atony of the walls of the bladder; also, that this retention had been aided by blood-clots blocking the entrance of the urethra, the clots having come from an injured kidney.

It was my belief also that the walls of the bladder were powerless to empty the organ, as a result of the previous overdistention, a result not at all uncommon in this class of cases. At any rate, I determined to act on the suggestion of the patient and "wait and see;" accordingly he was placed in bed, given the regulation dose of quinine, and hot fomentations were applied to the abdomen with the view of preventing as far as possible the occurrence of a chill and urethral fever. I find in the history of the case, as entered in the hospital records, the following reasons why the case was not thought to be one of rupture of the bladder at that time. They are of present interest, because they were made in the presence of many of the hospital staff, and indicate the line of reasoning that was employed in the face of the emergency.

I. Because the patient had emptied the bladder an hour and a half before the accident.

The patient's statement in this matter was considered true for the following reasons: *a*, the patient said he was a temperate man; *b*, he had never suffered from disease or injury of the urethra; *c*, no obstruction existed in the urethral canal.

II. It was not believed that the wheel had passed to the median line of the body, or to the cavity of the pelvis even for the following reasons: *a*, The patient was sure that he had been "pushed along in front of the wheel," and that no part of the wheel passed on the body. *b*, The situation of the ecchymosis substantiated the patient's statement in this respect. There was no apparent injury of the tissues at the median line of the body, nor at the right side of the pelvis. *c*, The pelvis was not fractured. *d*, The bladder could have contained but little, if any, more than three ounces of urine at the time of the accident, which amount was believed to have been too small to expose the bladder to the danger of rupture from the pressure of the wheel, even assuming it to have passed across the pelvis in front, without causing fracture or separation of the bony brim. *e*, The conclusion is substantiated further in a degree, by the fact that only about sixty-five ounces of fluid (so far as known) had collected in the body of the patient during the first forty hours following the accident. All things being normal, about eighty-five ounces should have collected, on the basis of fifty-one ounces per diem. At any rate the inference is a fair one, from this point of view, that the amount of urine in the bladder was small at the time of the accident. It is true, no doubt, that less urine was excreted than normally during the forty hours following the accident, owing to the accident itself, and to changes in the surroundings, and inclinations of the patient during this time.

III. The absence of all rational symptoms of peritonitis.

IV. The fluid injected at the first trial (16 ounces) was all collected and measured, except half an ounce which was charged to the dribbling that happened at the time. On the second injection 14 of the 16 ounces were returned at once, with an estimated half-ounce loss from dribbling. The missing 1½ ounce was thought to be still remaining in the collapsed bladder.

V. It was believed that the left kidney had been injured by the wheel, that the blood-tinged urine resulted from this injury, and that the small obstructing blood-clots noticed at the onset were moulded by the ureter of the injured kidney.

In this connection I desire to address two questions to the members of the society.

1. How much urine will an over-distended bladder contain in a living adult patient having a normal urethral canal? 2. How much, if any, of this urine will fail to escape through an unobstructed catheter aided by manual pressure?

It was my belief that the wheel of the cart had struck against the crest of the left ilium first, then, as the "body was pushed along by it," the wheel slipped from the crest upward, and its force was thus applied to the left lumbar region and to its contents; facts that were substantiated by the assertions of the patient, and the area of ecchymosis located thereat.

April 13th.—The patient could not urinate. A small quantity (℥ j.) was drawn with a catheter by the house surgeon, then the stream was suddenly and completely arrested. Six ounces of Thiersch's fluid were then introduced without withdrawal of the catheter, followed by the withdrawal of 25 ounces of high-colored fluid containing a few small blood-clots. Patient lying in bed reading the daily papers and not complaining of any discomfort. Temperature, 98½° F., pulse and respiration normal. No nausea nor vomiting.

April 14th.—Thirty-four ounces of clear urine drawn today without difficulty. No pain, tympanites, nausea, nor vomiting; no unusual tenderness on pressure. Bowels constipated, temperature, 98½° F. Read the papers as usual. Seen to-day by Dr. Alexander in consultation; no change of treatment suggested.

April 15th.—Appears brighter to-day; sixteen ounces of clear urine drawn. Bowels moved with an enema; sat up in bed and read the papers; desired to go home. Pulse, 90; respiration, 20; temperature, 98½° F.

April 16th.—Fourteen ounces of clear urine drawn to-day. Slight pain and tenderness over lower portion of abdomen. Vomited two or three times to-day. Seen in consultation by Dr. L. A. Stimson, who, while not inclined to think that the kidney had been injured, advanced the idea of rupture of the bladder at the prevesical space, but did not feel sufficiently certain of this diagnosis to advise operation. Patient rose from bed to-day and walked around the ward; was anxious to go home, as he said he was not injured sufficiently to remain in the hospital. Temperature, 98½° F. *per rectum*; pulse, 98; respiration, 22.

April 17th, A.M.—No pain, vomited occasionally, read the morning papers sitting in bed. Temperature, 98½° F.; pulse, 98; respiration, 22.

12 M.—While sitting in bed reading the papers, and after again expressing a desire to go home, he suddenly became unconscious, and died before the house surgeon could be summoned and arrive at the bedside.

Autopsy.—The autopsy, such as it was, could be secured only with the greatest difficulty, the body of the patient having been removed home almost immediately by permission of the coroner. Had it not been for the final aid of the coroner, granted by personal request, an examination would not have been permitted by the friends. However, Dr. Houghton, the house surgeon, armed with the coroner's letter, visited the prem-

ises and secured permission to make a small opening into the abdomen in the presence of the friends, but was not permitted to examine the kidney or to remove any portion of the remains as evidence of the injury. Still, through this opening the following facts were ascertained:

1. An intra-peritoneal rupture at the posterior wall of the bladder two inches in length, situated near the bottom of the recto-vesical space.

2. A firm agglutination of the intestines in the pelvic cavity, behind the bladder, circumscribed in arrangement, forming a "false bladder," so to speak.

3. Evidences of beginning general peritonitis.

This case proved most instructive to me for the following reasons:

1. It indicates that the bladder could be ruptured by strong pressure disadvantageously applied from above, one hour and a half after urination; or, that the force of the fall caused the rupture, which does not seem possible.

It seems probable that the wheel did press into the pelvic cavity, the convex portion of the wheel reaching deep enough into the cavity to compress the bladder and rupture it.

This pressure must have occurred while the wheel was pushing the body along the pavement in front of it, the pelvic cavity being directly in front of the wheel. I do not believe that the wheel pressed directly into or across the pelvis, for if such had been the case both sides of the pelvis would have been contused and the pelvis fractured, no doubt, since the load was estimated at one ton weight.

2. It indicates the possibility of the formation of a "false bladder" by localized adhesion of the intestines due to the circumscribed inflammation excited by the extravasation of a small amount of urine; also, that the physical signs of the filling and emptying of this false bladder may be identical with those of a normal bladder.

3. It indicates that peritonitis existed, due to rupture of the bladder and extravasation of urine into the peritoneal cavity, without the appearance of the rational symptoms of peritonitis.

4. It indicates that Weir's test for rupture cannot be relied on under all circumstances, except it be assumed that all of the fluid injected can be returned, which does not seem possible if the bladder be collapsed from overdistention.

5. It emphasizes the fact that a patient may die suddenly of collapse, due to septic poisoning, without the appearance of symptoms indicating its existence.

6. It suggests the importance of the injection of a small amount of fluid to clear the eye of a catheter, when obstruction to the eye of the instrument is thought to be due to blood-clot.

7. It demonstrates that when rupture of the bladder with extravasation is to be differentiated from retention of urine, a rectal examination of the base of the bladder to determine the degree of distention should *always* be made before any operative procedures are employed.

8. Finally, it teaches, in no uncertain tone, that when one is called to see a case for the first time, he should examine it from all standpoints completely and carefully, not do as I did in this one, begin where the previous attendant left off.

As I look back over this case, I am forced to the conclusion that three elements of it, only, were the cause of the failure of a fuller appreciation, on my part, of the vesical and urinary signs and symptoms suggestive of rupture: 1. The belief that the kidney had been injured, thus accounting satisfactorily to myself for the modifications of the character and amount of urine. 2. The belief that the bladder could not have been ruptured, in so empty a condition, by the wheel of the cart, without the occurrence of more serious injury to the pelvis. Finally, that the collapse of the bladder due to overdistention accounted for its failure to return the entire amount of fluid introduced to test the existence of rupture.

SOME ANTISEPTIC PRECAUTIONS DURING ATTENDANCE UPON CONTAGIOUS DISEASES.[1]

By WILLIAM P. NORTHRUP, M.D.,

PATHOLOGIST TO THE NEW YORK FOUNDLING ASYLUM.

Mr. President and Members of the Society: My reason for appearing before you with a subject differing from that set down against my name on the programme is that, on further reflection, I have chosen more wisely. I wish to present for your consideration a subject which is just now assuming greater importance than ever before in the profession at home and abroad. It is this:

How may the physician in attendance upon contagious diseases protect himself and his other patients from infection?

To point the discussion I will limit it to diphtheria. If you share with me the belief that the infection of diphtheria is communicable both by contact and transportation, you will share with me the dread lest the physician himself may become the carrier. In looking into a child's mouth the tongue-depressor may excite sudden cough and the clothing of the examiner become bedewed with spittle; in syringing a diphtheritic pharynx or nose, spasmodic recoil may project a tiny colony of germs upon some garment.

I have the unpleasant remembrance of more than once, in my early experience, starting to leave the house, after intubation of a diphtheritic patient, with a good-sized piece of false membrane clinging to my shoulder or to my sleeve; I have often felt particles from the mouth of the patient fall into my eyes and nose and upon my lips. I confess to you that, month by month, I have come to loathe, more and more, the condition which makes my person the possible medium of infection from child to child. I have gradually become so sensitive upon this point that I spend nearly as much time trying to protect myself and my friends from infection through myself as I do in visiting diphtheritic patients.

In New York, diphtheria is endemic. My habitual practice now, among children, is to isolate all cases of tonsillitis having any kind of exudate upon the tonsillar surface, and with the child to isolate a nurse. If the patient develops characteristic diphtheria all communication with the rest of the household is cut off; the meals of the attendant and all needed articles are left at the door. At each visit I remove my coat in the hall, bare my arms to the elbows, pin a sheet before me in such a manner that the sheet shall cover my person from chin to elbows and shoes. Having done this I put on glasses for the protection of my eyes. There is no case in which it is not necessary at each visit to inspect the throat, scarcely a case in which washing by syringe is not needed, and many times it is required to make local applications. Furthermore, every house, however poor, can set aside a sheet for the use of the doctor. On leaving the room I remove the sheet, fold it in such manner, that the side next my clothing shall at the next visit be in the same relation; having folded it I pin it. I have also calico gowns made of such liberal pattern as to wholly envelop my person, neck to wrists and thence to shoes. I find, however, that this unusual apparition does not always meet the approval of the child—frightens it, and the sheet does not.

For tongue-depressor a spoon serves the best purpose, is familiar to the eyes of the little patient, and is easily cleaned. Moreover it is not difficult to procure as many spoons for such use as there are patients in the house. It seems to me the utmost disregard of good hygiene on the part of the physician to carry in his pocket a patent spatula or cleverly devised tongue-depressor for use from mouth to mouth.

Having finished the visit and laid aside the protecting

[1] Read before the New York State Medical Society, Albany, February 5, 1890.

sheet, the hands and arms can be washed with soap and water, the nails carefully cleaned, bichloride solution or creolin solution well soaked in, and the skin rendered soft by the use of olive-oil or some toilet preparation. A clean, fresh towel serves to finish the cleansing, and the doctor slips away to his outer garments and the fresh air, having done something in the direction of antisepsis in accord with the teachings of the day.

Now, what is to be done with the clothing of the child? How about the handkerchiefs, towels, napkins, toys? How about the pillow-cases, sheets, spreads? How about the small objects of value about the room? How about the mouth-washings and gargle-water, excretions of the body, etc.? To answer the last question first, I advise carbolic acid, five per cent. solution, or creolin solution for disinfecting what is to pass into the sewer; the prolonged use of bichloride has been found to injure the plumbing. For disinfecting the discharges from mouth and nose there is no safe way practically but by fire; a thick mass of tough, pseudo-membrane allowed to dry offers a resistance to solutions which opens the way to too many dangers. The discharges should be carefully caught in old cloth, and burned promptly; for the excretions, then, strong disinfecting solutions; for discharges from mouth and nose, *nothing but fire!*

For disinfecting those articles of value about the bed and about the room I take pleasure in recommending to you an apparatus which has afforded me much satisfaction.

This odd-shaped steam vessel which you see before you was spied out by Dr. T. M. Prudden, at an annual exhibition of the American Institute Fair in New York, about three years ago. Numerous placards and handbills announced to visitors at the fair that this apparatus was invaluable for cooking purposes; that the cooking was all done by steam. Among other recommendations it stated that the cooker could be trusted to take care of itself while the cook went to church; on her return it would have her dinner of meat, vegetables, and dessert, too, for aught I know, quite cooked, and without possibility of burning. To make a long story short, this clever device of a dyspeptic has nearly or quite supplanted all the expensive, imposing, felt-jacketed Berlin sterilizers in the leading laboratories of this country, and has even found its way, like coals to Newcastle, to Koch's laboratory.

In order to reserve time in my allowance in which to demonstrate the apparatus, I will omit all description of parts except to call your attention to the two prominent features: the shallow vessel at the bottom, which is practically an "evaporating dish," and the hood, which serves to form a steam-jacket about the sterilizing chamber. This apparatus is capable of effectually destroying all the varieties of disease-producing germs which are now known. It is known as the "Arnold Steam Sterilizer."

It may be briefly considered under the following heads:

I. On what principle does it work?

II. What proof have we that it is effectual?

III. Of what practical use is it?

I. On what principle does it work? In answer to this question I quote from an article by Dr. T. M. Cheesman, Assistant in Bacteriology, College of Physicians and Surgeons, New York, published in the MEDICAL RECORD of July 13, 1889: "Sterilization is accomplished by bringing the object to be sterilized to the temperature of live steam (moist) and maintaining it at that temperature for about forty-five minutes. Boiling for the same length of time in a vessel, the sides of which are exposed to the air, is not sufficient, as the temperature in different parts of the vessel is found to vary considerably. . . . Numerous tests have shown that with a single Bunsen burner, and ordinary gas-pressure, the temperature of 100 C. is reached in all parts of the receiving vessel in less than ten minutes. . . . When the temperature of 100 C. is reached sterilization has commenced, and should be continued for the time specified, forty-five minutes, which time is necessary on account of the great resistance of the spores." These careful statements were made in connection with the subject of sterilizing milk for which this apparatus was recommended by Dr. Cheesman. After careful measurement of the temperature in every angle and against all the walls of the sterilizing chamber he found that the thermometer registered uniformly 100° C., or 212° F.

II. What proof have we that it is effectual? In answer to this question we need only state that every great laboratory of New York, Brooklyn, Boston, and Baltimore is habitually using to day this apparatus for preparation of its culture-media. This may be regarded as the crucial test of any method of sterilization, *i.e.*, that it can be depended on systematically to prepare susceptible fluids for culture-media, such as agar-agar, gelatine, beef-tea, etc., germ-free, to await indefinitely implantation of selected varieties of bacteria. The slightest accidental cloudiness of nutrient bouillon destroys its usefulness. It must await the inoculation of germs carried upon the platinum wire, at the will of the bacteriologist, and grow nothing else, or it is useless.

III. Of what practical value is it? Of what value is it to have a light and easily transportable cheap apparatus, of five-gallon capacity, capable of effectually sterilizing all objects which, from their size and quality of material, can be admitted to its chamber and exposed to live steam? Of what value is it in connection with contagious diseases? Here again this discussion must be shortened to a mere recital of facts supplemented with demonstration. The copper sterilizer here shown is already a veteran in service; and in many a campaign has proved a faithful body-guard. My practice is to send it at once to the room of the diphtheritic patient, place it over a gas-stove or Bunsen burner, fill the reservoir with water, and let it await the accumulation of soiled clothing. It should be closed except at the moment of thrusting in additional pieces. When sufficient is gathered the gas-stove is fired for two hours, after which time the disinfected garments, handkerchiefs, towels, etc., are transferred to a boiler and sent to the wash. I have found it a satisfaction to have in waiting, near at hand, this disinfecting apparatus for articles which are of value, which apparatus accomplishes its work promptly, without wetting, staining, or rotting the fabrics. There is no rolling the soiled garments into a bundle and throwing them out of the window, no soaking in the bath-tub, no dissolving them in corrosive fluids, no streaking them with dirty-brown or blackish stains—in short, no wholesale destruction of the contents of the sick chamber. After the case is finished, the bedding, including pillows, the clothing of the child, toys not glue-fastened, may be passed through the sterilizer and afterward washed and aired, and not wastefully destroyed. I have known paper-bound books, willow baskets, colored tidies, lacquer-ware, camel's-hair shawls, and various and sundry objects of bric-a-brac and virtu, after a two hours' imprisonment, withdrawn from the sterilizer disinfected and quite unharmed. It must be borne in mind that live steam scarcely dampens the objects. If we quickly withdraw the contents of this steam-chamber while at a maximum degree of temperature, the fabrics will be very hot, scarcely damp, and will become quite dry in less than a minute if exposed freely to the air. The garments of the physician may be disinfected in the same manner. I hope to demonstrate to you that ordinary cheviot material, carefully folded and quickly dried, will not be crumpled nor creased.

To some this five-gallon copper sterilizer may seem expensive for simple disinfection in contagious cases. It is just as valuable in the office of the surgeon for disinfecting bandages, dressings, instruments, and sutures. To the physician it is serviceable in sterilizing milk for babies; with the attachment here shown it makes the best "croup kettle" I have yet tried, making more steam and heating the room less. In an old ladies' home which I visit I have made many friends by using this as a steam inhaler, turpentine or eucalyptus lending itself to the purpose most admirably, while many an old lady has, as she be-

lieves, been cured of peritonitis and pneumonia by hot flannels prepared in the sterilizer. There is one further purpose for which it seems very well adapted and that is for steaming or steam-sweating patients waterlogged in Bright's disease. This two-gallon tin sterilizer, with spout having any number of joints for prolonging it, can be regulated to give any degree of heat without the attendant risks of setting fire to the bedding. A small burner and long spout will accomplish the desired purpose most satisfactorily.

Briefly to summarize what I have to say in recommending to you this disinfecting apparatus, known as the Arnold Steam Sterilizer, I repeat that:

I. All known disease-germs with their spores are destroyed by prolonged exposure to steam at an unvarying temperature of 212° F.

II. Experiment and the daily experience of the bacteriologist has proved that this apparatus maintains the required temperature in steam, and that it is an effectual sterilizer.

III. It is of practical use to the physician for sterilizing clothing, bedding, and other fabrics in contact with contagious cases; to the surgeon for disinfecting bandages, dressings, and instruments; to the hospital, nursery, and infirmary for steam-sweating dropsical patients, steam inhalations, "croup-kettle," sterilizing milk, heating flannels, making and reheating poultices, etc.

These recommendations are founded on personal experience, and I cordially lay them before you, hoping you may, in testing the truth of them, find what I have found —much satisfaction.

DISINFECTION DURING AND AFTER THE ACUTE INFECTIOUS DISEASES.[1]

By G. W. McCASKEY, A.M., M.D.,

PROFESSOR OF THEORY AND PRACTICE OF MEDICINE, AND CLINICAL DISEASES OF THE CHEST AND NERVOUS SYSTEM, FORT WAYNE COLLEGE OF MEDICINE, FORT WAYNE, IND.; FELLOW OF THE AMERICAN ACADEMY OF MEDICINE; PRESIDENT OF THE FORT WAYNE ACADEMY OF MEDICINE.

THE highest aim of modern scientific medicine is the prevention rather than the cure of disease. The list of preventable diseases is so large and their fatality so great that complete suppression would render necessary the reconstruction of the entire fabric of statistical sociology, and mark an unprecedented era in the physical condition of the human race. This end would be in great measure accomplished if the acute infectious diseases could be stricken from the calendar. That this is within the range of possible achievements will not be seriously questioned by any one thoroughly conversant with the facts. How best to do it is the real question at issue in this field of medical thought.

As a condition essential to the attainment of the best results of systematic disinfection, perfect isolation must be insisted on. Without this our best directed efforts must fail. The ignorance and selfish obstinacy found at opposite ends of the social scale, coupled with no small amount of apathy or something worse on the part of the profession, are accountable for the too general disregard of this vital precaution.

Coming now to the immediate question of disinfection the first problem that presents itself for solution is the selection of such germicidal agents and methods as will be at the same time reliable and practical. To be reliable they must stand the test of laboratory experiments, fairly conducted and reasonably interpreted; to be practical they must not be too complicated nor too expensive. The problem is a compound and intricate one, and must be resolved along different lines. A given germicidal agent or method, for instance, may or may not be effective in the presence of the albumin or fat so lavishly distributed among the household effects of certain classes; and those, too, in which infectious diseases most largely prevail. Thus mercuric chloride solution, harmless to wooden surfaces, would ruin silverware; while heat, so widely applicable, would damage rubber goods.

I will first ask your attention to the fumes of burning sulphur—sulphur dioxide. This agent, because of a reputation established in the pre-experimental era, its convenience, some actual germicidal power, and an odor which, it must be conceded, is strongly suggestive of tangibility, power, and general destructiveness, still retains a reputation which it does not deserve. From a practical point of view the most important investigation with which I am acquainted is that made by Dr. Kinyoun, at the quarantine station below New Orleans, under the auspices of the United States Marine Hospital Service. The results were submitted to Surgeon-General Hamilton, and published in the *Weekly Abstract of Sanitary Reports* for June 29, 1888. Cultivations of various organisms were exposed to the fumes of burning sulphur in a very thorough manner, with the aggregate result of killing the germs in sixteen out of seventy-four instances—or a little more than twenty-one per cent. In one experiment the oft-repeated statement that the germs in culture-media were inaccessible to germicides, and that the failure of the latter under such conditions is not proof of its inutility in clinical medicine, is shown in a most conclusive manner to be erroneous. In this instance cultivations on agar-agar were exposed side by side with those on rags, to the sulphur fumigation for twenty-four hours. Of the agar-agar cultures three out of eight were killed, while of those on woollen rags not one was destroyed. This would seem to indicate that such tests, instead of being too rigorous, were not severe enough. Indeed, the circumstances in which the infectious germs are frequently found, such as being mixed with filth, deeply imprisoned in dense textures, etc., fully justify the assertion that they are more inaccessible to germicides in the sick room than in the plate-cultures of the laboratory.

Wernich failed to kill the bacteria of putrefaction by exposure to an atmosphere, 3.3 per cent. of which was sulphur-dioxide. Schatte and Gartner failed with six per cent. Koch subjected bacilli for ninety-six hours to an atmosphere which contained 6.13 per cent. at the commencement, and 3.3 per cent. at the close of the experiment with entirely negative results. On another occasion, however, he obtained the contradictory result of killing the bacillus anthracis by exposure for one hour to a very moist one per cent. atmosphere. But the germs were devoid of spores and did not therefore possess their usual vitality. Sternberg poured liquid sulphur-dioxide upon the bacilli of anthrax without impairing their germinating power when removed to a suitable medium. He also killed micrococci (which are always sporeless, and therefore easily destroyed) by exposure in a dry atmosphere to a twenty per cent. mixture of the gas (Sternberg).

As showing inferentially the estimate of one quite eminent authority it may be stated that the extensive tables of Miquel, classifying no less than sixty-five germicides, ranging in power from those "eminently antiseptic" through six classes down to those "very feebly antiseptic," do not accord a place to it anywhere in the scale. So much for experimental proof.

If we now turn to the results of clinical observation, we find them to be very far from satisfactory. Dr. J. Lewis Smith reports a case of scarlatina; after which the room was fumigated from morning till evening; two months later, a little girl spent a few days in the house and was taken with a fatal form of the disease. She came from an inland town without evidence or suspicion of other exposure. Such instances he says are not uncommon.

In a recent article by Dr. Cyrus Edson, Chief Inspector of the Health Department of the City of New York (New York MEDICAL RECORD, November 16, 1889), we are informed that nearly every room in New York City in which there had existed a case of small-pox, measles,

[1] Read before the Michigan Southern Medical Society, at Hillsdale, Mich., December 10, 1889.

scarlatina, or diphtheria, had been fumigated with sulphur-dioxide; and that his "wide experience had led him to the conclusion that it is a thorough and almost perfect destroyer of the infective matter of the acute exanthemata and diphtheria." A conclusion of so great importance, expressed with such emphasis, and by one whose high official sanitary position carries with it a certain semblance of authority, is entitled to a careful consideration. Rendered somewhat sceptical by the well-known facts above cited, we turn expectantly to the records upon which his conclusions are based. Collected from a certain territory and time in New York (presumably not the most unfavorable selection) here they are: 326 cases of small-pox, no secondary cases; 515 cases of diphtheria, 114 secondary; 626 cases of scarlet fever, 135 secondary; 557 cases of measles, 163 secondary. Thus in a total of 2,024 cases, 1,612 were primary, and were followed after fumigation by 412 secondary cases; the latter being more than twenty-five per cent. of the former. Dr. Edson explains, however, that only 102 of the secondary cases occur late enough to preclude the possibility of direct exposure to the primary cases. But even this number (102) is 6.3 per cent. of all the primary cases. In other words, it is admitted in regard to this "perfect destroyer" of infection, that every 1,000 cases of the acute exanthemata will give rise, in addition to the victims caused by direct exposure, to sixty-three more, which owe their existence to germs derived from rooms that have been subjected to sulphur fumigation. If we do not accept the explanation which disposes of three-fourths of the secondary cases, attributing them to infection obtained prior to fumigation, the number would be 250.

These facts scarcely fulfil the expectation awakened by the announcement of such a conclusion. But when we learn that the removal of the clothing, mattresses, etc to a properly equipped disinfecting station is a part of the plan recommended and presumably practised, it may well be considered a debatable question how much greater the number of secondary cases would have been without the sulphur fumigation.

While the facts seem to fully warrant the conclusion that sulphur gas, as a germicide, is, to say the least, capricious and unreliable in its effects, yet it has, of course, some value. Its efficiency will depend in great measure, as indicated by Dr. Edson, upon the quantity of moisture which the atmosphere contains. In the fumigation as practised by the New York City Board of Health the sulphur is ignited and burnt with four ounces of alcohol. Considerable importance has been attached to the quantity of vapor produced in the combustion of the alcohol, as furnishing the needed moisture in the room. The quantity of steam thus formed was estimated at fifty quarts. I will be responsible for the assertion that the vapor produced by the four ounces of alcohol is about two hundred quarts, instead of fifty; my estimate being based upon the molecular weight of alcohol and water and the chemical reaction of the combustion of the former; yet it is still very far from sufficient to meet the demands. In order to get the full effect of the sulphur the atmosphere should be saturated with moisture.

If sulphur fumigation must still be used as an auxiliary in the disinfection of houses, let it be under the most favorable conditions. Let it be provided that the air shall be surcharged with moisture. Of course, the hotter the room the better, as it will take up more vapor, and thus render the SO_2 more effective. If in excess, the watery vapor (containing the sulphur dioxide in solution) is undergoing constant deposition upon all exposed surfaces, which are being bathed in, or at least moistened with it. But when made as effective as possible, the evidence showing that as a germicide it is unreliable and capricious in its effects seems to me entirely conclusive. It should not be relied upon alone, even for the disinfection of the chamber walls and such furniture as cannot be removed to the disinfecting station. Postponing the further consideration of the proper methods of dealing with these non-transportable articles, I will next discuss the most important question, in my opinion, relating to the entire subject; that is, the construction of the disinfecting station, to which an allusion has just been made.

An institution of this sort, provided at public expense, is absolutely indispensable to the attainment of success in the struggle with the acute infections. For various reasons, among them the prejudice, ignorance, and poverty of the masses, and the technical skill and knowledge and large expenditure of money required, it is by some such provision alone that the conditions of the problem can be met. Mutual protection from a common danger both justify and require the interposition of the police power of the State. The feasibility of this plan is no longer a question for discussion. It has been practically demonstrated, and has received the highest endorsement. Its further development and final adoption by the civilized world will be a part of the future history of sanitary reform. In view of its great importance, and the desirability of having a single appropriate term to take the place of "quarantine apparatus," "disinfecting station," "disinfecting apparatus," etc., I will venture to suggest the word "Disinfectory," as applicable to the various institutions designed for practical disinfection. It seems to possess the desirable qualifications of brevity and a legitimate etymological ancestry. It has, moreover, received the sanction of a friend competent to judge of such matters, and will, henceforth, be employed in this paper.

In regard to the processes to be adopted in a disinfectory, we are, fortunately, at no loss to decide. Steam, confined in compartments strong enough and tight enough to permit a pressure of from fifteen to twenty-five pounds, is the very best method known, and absolutely reliable. In the disinfectory connected with the quarantine station near New Orleans, the steam is applied at a maximum pressure of seven pounds. At this pressure the steam has a temperature of 220° F.; at fifteen pounds it would be about 250°; while at twenty-five pounds it would be 275° F. The experiments of Dr. Kinyown, above referred to, proved that the finest fabrics, such as silks and laces, were not impaired by this treatment. The apparatus now in use by the Louisiana State Board of Health consists of a series of cylinders, each fifty feet long and nine feet in diameter, one end of which swings open as a door, or dome, closing and clamping steam tight. A number of racks for the purpose of carrying the articles to be disinfected, are attached to a car which runs on a removable track, thus enabling the racks to be run out and filled and returned, after which the track is removed and the door or dome closed and fastened, and the steam, accessory provisions for which have, of course, been made, turned in. After thirty minutes' exposure, the steam is allowed to escape, the dome swung open, and the goods removed.

The expense of such an institution depends upon the capacity for work which it will be required to possess. The one at New Orleans, which has to deal with the entire cargo of a ship at one time, cost $10,000. Dr. Williamson,[1] the president of the Louisiana State Board of Health, has recommended for Government use a portable apparatus built upon a flat car. Its cost is from twelve to fifteen hundred dollars. Several of these have been constructed. They could, of course, be made for less money if permanently located, thus avoiding the expense of the flat car, which a railway official informs me costs about $400. The net cost of the apparatus, which, of course, includes some sort of sheltering inclosure,

[1] I am indebted to Dr. Williamson for a very courteous and painstaken letter, in which he says that their apparatus has been copied by Galveston, Tex., Charleston, S. C., and the United States Government; and that plans are in process of construction at San Francisco and other places. He expresses the belief, in which I fully concur, that "within five years it will be in use in all quarantine stations." I will add the prediction that in that time, this or a similar apparatus will be in active operation in all the centres of population.

would thus be less than $1,000. It is entirely practicable, so far as expense is concerned, to supply every community in the United States, excepting, perhaps, the most sparsely settled localities. with a disinfectory commensurate with its needs.

It is not claimed that the apparatus in use at New Orleans is perfect; yet in view of the probable fact that no better disinfecting agent than steam will ever be found, it is difficult to see wherein any radical improvement can be made. Those who have been instrumental in bringing it to its present state of development are entitled to the gratitude of the civilized world. If infected goods are subjected for one hour to super-heated steam in this or any suitable appliance, it may be regarded as practically certain that no disease-germ will survive the ordeal. Indeed, the investigations of the committee of the American Public Health Association, showed that all the germs experimented on, which included the bacillus anthracis and other "tough" specimens, were killed by five minutes' exposure to steam at a temperature of 212° F. The higher temperature, however, is desirable, because it is more rapidly effective. and because the associated pressure insures the permeation of the steam through the interstices of dense, heavy textures, such as mattresses and the like, which might otherwise escape.

Displacement of the steam by superheated air under a very low pressure, would insure the complete removal of all moisture from heavy upholstery, woollen goods, etc. This would remove one objection to the steaming process on the part of those whose full co-operation is desirable, if not essential, to full compliance with a law which will be looked upon by many of the lower classes as an infringement of personal liberties. and treated with studied neglect if not outspoken animosity.

The removal of the goods to the disinfectory involves a possible risk of spreading disease. It can be entirely obviated by the use of paper sacks and wrappers, which are practically impervious, and possess the additional recommendation of cheapness. They can be supplied in abundant quantities, by reason of their cheapness. and should. of course, be burned as soon as the goods are removed.

Assuming now that everything that is portable and amenable to its processes (which, of course, includes facilities for burning whatever is to be destroyed) has been removed to the disinfectory, the floor, walls, furniture, etc., remain for consideration. Everything which can be subjected to that best of chemical disinfectants, mercuric chloride, should be thoroughly treated with a 1 to 1,000 solution. The only prerequisite is the removal of dirt (which might contain albumin or grease), from the various surfaces to be washed; for in their presence it has practically no germicidal power. To effect this they should be washed with a strong solution of some very alkaline soap, which is itself not wholly destitute of disinfecting power. The greatest care should be taken to insure the introduction of the fluid into all crevices, joints of furniture, and other inequalities of surface, where disease-germs might escape contact with the fluid. One of the greatest difficulties met with is in dealing with upholstered furniture. Of course it ought not to be in a sick room, if it can be replaced by that made of willow or similar material, which can be easily disinfected. However, when exposed, as it often must be, it should either be saturated with the mercuric chloride solution, or the cloth removed and both it and the padding sent to the disinfectory to be treated with superheated steam. which can be done without the slightest injury. The only proper way to deal with papered walls is to saturate the paper with the mercury solution, or some equally potent germicide, and then have it removed. to be replaced by new when the disinfection is complete. Carpets should either be submerged in the solution or treated with the superheated steam. Any metallic or other surfaces which would be injured by the mercury ought to be treated with some reliable non-corrosive germicide, such as a five or ten per cent. solution of carbolic acid.

It is unnecessary to detail the evidence in favor of the efficiency of mercuric chloride as a germicide. It is well known and altogether conclusive. Its objectionable features are its corrosive and toxic properties. These, however, can be easily obviated by the exercise of reasonable caution and intelligence.

The subject of corporeal disinfection involves two distinct and very different factors, viz., first. the patient. who is the hot-bed in which the germs are multiplied and from which they are distributed in quantities practically unlimited; and, second, those in attendance as physician or nurse, who may act as carriers of the poison. In respect of the former the question must be answered with regard to the particular disease confronted. Antiseptic baths as strong as can be used without undue irritation, would undoubtedly diminish the virulence of poison emanating from the skin. Their action and results, however, could only be temporary, and their use ought to be guided by the hydro-therapeutical indications of each case. If they are contra-indicated from this stand-point, the benefits which can reasonably be expected are insufficient to warrant their use. Inunction with some oleaginous substance, which can itself be made mildly germicidal, indirectly accomplishes the object by preventing the dissemination of the dry cuticular scales.

Of course all excrements should be subjected to the action of a reliable germicide. On account of the frequent presence of albuminous compounds in the various excreta, mercuric chloride is not the best germicide which can be selected for their disinfection. Chloride of lime solution, in the proportion of four ounces to the gallon of water—the No. 1 standard solution of the Committee of the American Public Health Association — probably meets the demands of economy, convenience, and potency better than anything else. It should be kept in all receptacles intended for these products. thoroughly admixed with them and left in contact for several hours.

Clothing which needs cleansing during the progress of a case should either be sent to the disinfectory or macerated in a 1 to 1,000 solution of corrosive sublimate for twelve hours, and then boiled. Plates, knives, forks. glasses, cups, etc., should be treated with five per cent. carbolic acid solution, and afterward boiled.

A gargle composed of some mild germicidal solution is rationally indicated in diphtheria and scarlet fever, both for the patient and those who are in more or less constant attendance; in the latter as a prophylactic, and in the former to weaken the virus generated in the throat. with the view of diminishing the danger both of auto-infection and of transmission to others. For this purpose Listerine is a very pleasant and sufficiently powerful agent. Combined with water, in the proportion of one to four, it forms a very agreeable mixture. It could be also used in the nasal cavities in the form of a spray to good advantage.

The physician is very often the bearer of infection. The problem of keeping himself free from it during his daily rounds it must be conceded presents many difficulties; but they can and should be overcome in the interests of humanity. If it takes time and trouble they should be given, but the physician ought, by all means, to be compensated for the extra labor involved. It is not for his individual but the public good, and it should not be required of him as a donation. Calling the attention of the laity in such a persuasive manner to the methods of transmission of disease-germs and the care required to prevent it would have for them an educational value.

Briefly, the outer garments worn while visiting cases of infectious disease should be removed. The physician should avoid sitting down in the infected room; and should limit his contact with the patient and the various articles of the room to his hands, or better, one hand. The hands should always be washed with a reliable germicidal solution before leaving the room.

Nurses ought to be subjected to thorough and com

plete personal disinfection before being permitted to leave the sick chamber.

There is much that remains to be worked out in dealing with the various infections; but the accumulated facts would seem to justify the formularization of a detailed and comprehensive plan, the complete fulfilment of which ought to pronounce their doom. When the various disease-germs have been isolated and separately studied experimentally, it will undoubtedly be found that variations in technique will be advisable in dealing with the different species. Whether the results of these variations will be of such importance as to demand their practical recognition is a question which cannot yet be answered. In the present state of our knowledge the agents and methods enumerated are, in my opinion, entitled to the greatest measure of confidence. If it is objected that the system is too complicated for practical purposes, the sufficient answer is that the end fully justifies the means. The outlay would be of the most remunerative kind, even if we estimate the value of the human life and labor which it is possible thus to save on the low plane of social economics. Their actual cash value to the commonwealth would more than justify the seemingly large expenditures.

But is it really so complicated after all? Let us briefly summarize what is actually required: First, a well equipped disinfectory provided at the public expense and accessibly located; second, mercuric chloride solution, 1 to 1,000; third, chloride of lime; fourth, five per cent. solution of carbolic acid; fifth, sulphur (?). This does not appear to be either complicated or in any other way unreasonable. No unusual amount of skill or intelligence is required to secure its full operation.

Whether the plan outlined is in its details the very best or not, it is at least the legitimate outcome of experimental work. It is consistent with and endorsed by the facts and deductions of the laboratory, to which the clinician must look for the origination of methods and their ultimate verification in this department of practical medicine.

38 West Wayne Street.

EARLY EXPLORATORY INCISION IN ABDOMINAL SURGERY.[1]

By NEIL MACPHATTER, M.D.,

Denver, Col.

In choosing the above subject, I do so in order to advocate a principle which I consider of great practical value to our profession, and one which has not yet received that attention to which it is entitled. In taking a general survey of our profession, one is astounded at the number of complaints, especially among the diseases of women, that have been allowed to go unrelieved. In speculative moments, I cannot but reflect upon the wonderful advancement that has, within recent years, been made in elucidating many of the mysteries that have always surrounded abnormal conditions within the female pelvis; mysteries that would have continued to remain in obscurity and doubt, had not several of our surgeons shaken off the shackles and teachings of the elders, and revealed these diseases in a new and reasonable light. These workers have shown that many of the teachings of the old school could no longer be followed or sanctioned, and that the sooner the profession recognized that, in many instances, the treatment was to be rescued from the hands of empiricism and placed upon a firm scientific and surgical basis, the better for the profession and our patients. With the novice, as well as those who know but little of abdominal surgery, accuracy of diagnosis is looked upon as one of the essentials before an operation is undertaken. It is to endeavor to show the fallacy of such teachings that I have undertaken this subject. Had this been the guide and criterion of the pioneers of our profession, abdominal surgery had never attained its present proud position, if indeed it had ever struggled into existence. I have always maintained, and recent events have added to my conviction, that absolute accuracy in diagnosis of many conditions within the pelvis cannot always be determined. It is for this reason that much of the empiricism that is practised can be accounted for. It is my purpose in this paper, to-night, to give a short *résumé* of some vague conditions that can only be cleared up and successfully treated by resorting to exploratory incision.

Taking first the tumors of large size, such as the soft œdematous myoma, ovarian cystoma, parovarian cyst, and others, there are frequently conditions and symptoms of similarity that render a differential diagnosis puzzling and impossible. This should not, however, deter the operator from opening the abdomen, making his diagnosis and then removing the tumor, whatever kind it may happen to be. In many conditions of the tubes is this argument particularly applicable. A distended tube with an ectopic pregnancy, before the period of rupture, is in some instances absolutely impossible to distinguish, either by subjective symptoms or by physical examination, from a pyosalpinx. In either case our patient is in most imminent danger. There is but the thinness of parchment between her life and almost certainly fatal peritonitis, upon the one hand, and alarming, if not fatal, hemorrhage, on the other, which any sudden exertion may bring on. In fact, she is at the mercy of accidents, having no sufficient warning. Here, in either case, are tubes distended and whose walls are gradually getting so thin that they cannot resist further distention. They are liable to rupture at any moment, whether from the rapidly growing fœtus or from accumulation of pus, with almost certainly fatal consequences, and yet it is frequently maintained that we should withhold the knife from the safety and relief it affords.

There is yet more uncertainty in the diagnosis of those vague pelvic disorders for which the physician is so often consulted, and upon examination no tumor can be found. These patients are nevertheless in a serious state of health, and are gradually and surely getting worse. All manner of treatment will have been tried, such as rest, hot-water douches, blisters, pessaries, massage, etc., without deriving any but trivial results. The physician will shortly discover that his patient is verging upon the edge of chronic invalidism, with constant pain in the pelvis as a prominent symptom. Upon close examination it will frequently be ascertained that there has been inflammatory trouble following an abortion, normal labor, or one of the zymotic diseases. A typical case, illustrating the results of scarlet fever upon the ovaries, came under my care some time ago.

A young lady, aged twenty-two, consulted me some time ago, complaining of intense dysmenorrhœa. The history of the case was that she had always been a healthy girl up to the age of twelve years, when she had rather a severe attack of scarlet fever; menstruation began at fifteen, and was accompanied by a good deal of pain. The discharge was irregular and scanty. The period of most intense pain was during menstruation. For years this pain became more severe, and latterly was quite unbearable. So much so that she was confined to her bed for over a week each month. All manner of treatment had been without benefit. She was sent to me with the history I have given, and expressed herself as willing to undergo any operation rather than endure her eternal pain. By examination I could detect nothing abnormal, but the symptoms were such as to call for investigation. From the history and symptoms, I concluded the ovaries were cirrhotic as the result of the scarlet fever she had when twelve years of age. My diagnosis was simply a strong and well-founded suspicion gathered from having seen a number of such cases. I expressed my opinion to the young lady's parents, and recommended that they allow

[1] Read before the Denver Medical Association and Arapahoe County Medical Society, October 3, 1889.

me to make an exploratory incision, and if the condition justified any further steps, to go on. This they gladly accepted, and at the operation my suspicions were fully confirmed, for I found the ovaries quite shrivelled by cirrhosis, but still struggling to fulfil their functions. The operation had a splendid effect, the young lady has fully recovered; the pain has left her, and she looks the picture of health, and expresses herself in grateful terms.

In those conditions where the trouble is due to a previous pelvic peritonitis or parametritis, no distinct enlargement will be appreciable by physical examination, although there will be present many conspicuous changes in the cellular and connective tissues. These changes are due to extensive parametritic and peritoneal cicatrices, and keep the uterus and its appendages in a more or less fixed position, according to the number and direction of the remnants. These pseudo-membranous cicatricial bands may bind themselves in almost any conceivable direction. Frequently it happens that the ovaries and tubes are implicated and bound down, and matted together by these contracting membranes. They have by this time lost their functions irretrievably, and permanent sterility is the consequence. The argument advanced, that the removal of the tubes and ovaries in such cases unsexes the woman, is of course utter nonsense, as she is already unsexed as the result of the disease. In instances of this character, when, after every known line of treatment has been faithfully carried out, the duties of the surgeon are urgently justifiable to make an exploratory incision, remove the appendages, break up and drain away the adhesion. By this means one can restore to health and comfort many women, who would otherwise be tossed about from one physician to another, seeking relief and finding none.

Examples illustrative of this can be multiplied *ad infinitum* if necessary, showing that this principle of exploration is a necessary and a sound one, and that much suffering and many lives can be saved by its judicious application. The appeals, I might say warnings, frequently but not too urgently expressed, but becoming more recognized every day, that physicians delay too long in recommending surgical interference, is in few more needed than in this class of disease. An interesting case, both from a clinical and pathological stand-point, came under my notice while I was in the East.

A married lady, aged thirty-two, had been complaining ever since her last confinement, some eight years ago, of a great deal of pain in her pelvis. This pain was intensified at times. I ascertained she had several attacks of pelvic peritonitis. Gradually her suffering became more marked, and she had tried various lines of treatment. I was called in consultation, and although I could find but slight enlargement of the left tube, yet there was considerable binding down of the tissues on the corresponding side, and I felt satisfied that there was tubal trouble, and recommended an operation. This proposition was accepted, and the operation was performed a few days subsequently. It proved to be a very difficult one, as there were tense and rigid adhesions matting all the parts together. I hand you here for inspection the ovary and tube which I removed. You will observe there were a great number of adhesions, as shown by the specimen. You will also observe a state of affairs that is of very rare occurrence, and one which I have never before seen—that the tube is filled up with calcareous deposits. This woman recovered from the effects of the operation in a few weeks, and is now enjoying perfect health.

A disease, or rather a condition, frequently the result of congenital arrest of development, although occasionally arising as the result of inflammatory action, and known as infantile uterus, is one that has not received that attention which it deserves. In looking through what literature I possess, little mention is made of the subject. This is somewhat remarkable, for it is an anomaly sufficiently common to be quite distinctive. It is true, abnormalities in general, and defective developments of the female generative organs, have been investigated from an embryonal stand-point. Especially has this been done by Kussmaul and subsequently by others, who, however, based most of their hypotheses upon the works of Kussmaul. But the point I wish here to particularly emphasize is, that there is a condition of the uterus and appendages, of deficient development, that has clinical features and well-marked symptoms accompanying its presence, that has never yet been generally recognized by the profession as a peculiar feature of this lack of development; it is that it may not be general. As the uterus is made up of two entirely distinct parts, viz., the fundus and cervix, whose blood and nervous supply are entirely different and independent, so there can be a deficiency of development of the one with out the other being affected. Similarly, the tubes or ovaries may be infantile, and the fundus and cervix of normal size. When the error is limited to the body, the endometrium will retain its infantile state, and will not be in a fit condition for the adhesion or growth of a placenta; hence nearly all these cases remain sterile. The symptoms that accompany a typical case of infantile uterus are always pretty constant and characteristic. Generally, menstruation will be delayed in its onset, although it sometimes comes on at the usual time. When it does appear, it is scanty and irregular, and almost universally ushered in with a great deal of pain. This pain may be permanent, although it usually disappears for ten days or two weeks between each period. A remarkable fact about this pain, and one that is quite pathognomonic, is that it is most severe one or two days before menstruation sets in. The discharge will sometimes be so scanty as to be scarcely recognizable. When complete amenorrhœa appears, as it sometimes does, it is represented by moniminal symptoms, such as mucous discharge, pain down the back and thighs, vomiting, headache, and disturbances of digestion. If a patient comes complaining of a persistency of these symptoms, and especially if upon examination they can be verified by a small cervix or fundus, the diagnosis is complete. This, however, cannot always be accomplished. The treatment of this disease naturally suggests itself. It has been ascertained that nothing short of removal of the appendages, to hasten the menopause, has any effect upon such cases. The electric stem pessary has been tried and found disappointing. In patients of the wealthier class, who can afford to lie up ten days, or two weeks, and have what luxuries they choose, a miserable existence can be dragged along until the climacteric comes to their relief. It is otherwise with those who are obliged to depend upon their own exertions for a living, and he who will relieve their sufferings by an operation is doing a deed of charity. The difficulties of diagnosis, and the advantages derived from operative measures, are amply illustrated in a case of which I can here produce the specimen.

When I was under the teaching of Mr. Lawson Tait, a young lady, twenty-three years of age, married four years, was sent to him with the following history: She had no children. Ever since the onset of menstruation she had been suffering pain during her periods; as years went on this pain became more severe, and latterly was quite unbearable. It became necessary for her to lie up in bed, and to use morphia and hot applications to relieve her suffering. Since marriage the pain became more intensified. As a last resort she was sent to Mr. Tait for advice. No pathological condition from examination could be discovered, yet here was a woman whose existence was pitiable in the extreme. The physician under whose care she was had faithfully carried out all the usual remedies for such cases, and what his ingenuity could suggest besides, with no permanent benefit. The subjective evidence pointed so strongly to tubal disease that an exploratory incision was suggested. This was willingly consented to, as the woman was prepared to run any risk for relief. At the operation it was found that both tubes were quite inflamed, and much smaller than fully developed normal tubes. There were no fimbriated extremities. The outer part of each tube gradually diminished

in size, and blended into the folds of the broad ligament, where it became lost. They were removed together with the ovaries. The woman immediately regained excellent health, the pain entirely disappearing. From the fact that both tubes were similarly defective at their outer extremities, and both becoming lost in the broad ligament in the same manner, we concluded it was a congenital want of development, and not due to inflammatory action. Here was a woman laid up half her time suffering, life had become a burden to her, and the results clearly show that the operation was urgently demanded. Indeed, had it been done years ago, it would have been a blessing. Neither can it be said that she was unsexed, because, for obvious reasons, the ovum could not be grasped by the fimbriated extremities that never existed.

I do not, however, wish to be misunderstood upon this important matter. I do not advocate the radical idea that, whenever a pain or an ache is found to lodge for any length of time in a woman's pelvis, the surgeon should immediately rush with scalpel in hand and recommend an operation. Nor, indeed, would anyone in his sane senses think of such a thing. It has been this indecent haste by those who have had no special training, and who are incompetent to assume the responsibilities of such operations, but who are nevertheless led away by the seduction that hovers about the art of surgery, that has done much to impede the progress of this legitimate and honest branch of surgery. The evil results following operations done indiscriminately by men of unguided ambition, who recommend and perform them without sufficient knowledge of the subject, should not be laid at the door of the healing art; but rather look to those who, with too eager enthusiasm and wanting in the many fine points of diagnosis that can only be learned from experience, have not taken the time to sufficiently investigate the condition calling for operation. The more I see of abdominal surgery, the more convinced do I become that these operations should be left entirely in the hands of those specially prepared to do such work, and that they should not be done indiscriminately. What, therefore, would be perfectly justifiable for an experienced operator to do, would not be for the tyro. The experienced operator, who is familiar with the many doubtful symptoms, the complications and dangers that may be encountered at any moment, is prepared to meet them; whereas the general practitioner cannot be expected to be so. Measured by its brilliant results in the hands of experience and intelligence, abdominal surgery is the wonder of our profession. In the domain of removing diseased appendages for chronic incurable maladies, it has rescued many hundreds of women from a state of misery and pain to that of health and comfort. In the hands of those who have given this subject their sole attention and who know whereof they speak, the principle of resorting to an exploratory incision in suitable cases, after every other known means has been justly tried, is a necessary one for successful treatment.

Dr. Edis, of London, says on this subject: "There can be no doubt that thousands of women in the length and breadth of the land were suffering, as only women could suffer, whose condition was totally ignored or disregarded, and who were treated by purgatives, hot-water douches, caustics, pessaries, and what not, without deriving any but trivial benefits." He agreed with Mr. Tait that, when the symptoms justified their opening the abdomen, their duty was to do so. Formerly they merely tinkered about with pessaries, and their patients went unrelieved. He thought it ought to go forth that men in general practice ought not to allow their patients to continue for years to suffer, without having recourse to an operation which, on the whole, involved very little risk in competent hands.

Drs. Bantock, Barnes, Savage, and others hold strongly to the same view. Lawson Tait says that, in every case of disease of the abdomen or pelvis in which the health is destroyed or life threatened, and in which the condition is evidently not due to malignant disease, an exploration of the cavity should be made. Again, quite recently, he says, "Absolute accuracy of diagnosis in the abdomen is very far from being possible; only the ignorant assert that it is, and only fools wait for it."

It frequently happens that results of the most wonderful and marvellous kind follow an exploration, when nothing has been done but a drainage-tube left in. Thus, in enlarged spleen or liver with effusion, exploration is followed by a gradual diminution of the tumor and ultimate recovery. I have again seen a young lady, supposed, on exploration, to have malignant enlargement of the kidney. Nothing was done but a drainage-tube left in, and, to the amazement of all, she suddenly showed symptoms of improvement, and eventually returned to her home fully recovered. Why this is so I cannot say, any more than I cannot understand why papilloma, in two instances showing exactly the same features, are undistinguishable from each other under the microscope, is rapidly malignant and fatal in one, and is curable by mere exploration and drainage in the other; or why mere washing out of the abdominal cavity, with drainage, in tubercular peritonitis, is so frequently followed by a complete restoration to health. Persistent pain in the pelvis and enlargement of other organs are, beyond dispute, not infrequently cured in this inexplicable manner.

The greatest triumph, however, of this extended principle of exploration has been most apparent in those cases where tumors have been successfully removed, and our patients cured under circumstances apparently beyond the reach of hope, who were reduced to the lowest possible condition of health, and where the operation was begun under the belief that nothing promising or satisfactory could be accomplished.

Much of the success in the treatment of these complaints I have hurriedly enumerated is due to the fact of receiving them early. The "too late" cases form the great stumbling-block to successful treatment. It is pleasing to notice, however, that the profession generally are coming to recognize that all temporary procedures are to be condemned, as being the means of leading to distrust and complications. Let us, upon every occasion, exercise as much precaution and ingenuity as is possible against premature and unnecessary interference; but, on the other hand, let us liberate ourselves from the responsibility and stigma of being "too late."

ANOTHER PECULIAR EFFECT OF COCAINE.

By J. W. STICKLER, M.D.,

orange, n. j.

Not infrequently there appear in the various medical journals articles upon the untoward effects of cocaine. Recently Dr. John A. Wissinger[1] calls attention to a very unpleasant experience he had with a fifteen per cent. solution of this drug. In this case the injection of ten minims of the above solution was followed by distressing dyspnœa, pallor of face, dilatation of pupils, spasm of the flexor muscles of arms and legs; pulse, 140, very small and wiry; respirations, 40 a minute; perspiration, profuse. Patient at no time unconscious. As the doctor says: "This is not a unique experience." Not as rare in the past as it ought to be in the future, for with these warning notes sounding in our ears, we should exercise such caution as will render the repetition of similar accidents almost impossible.

The case I am about to relate differs from the one just quoted, in that the patient's life was not jeopardized, but it has one feature which, so far as I know, has not been commented upon by any writer. The case is as follows: John D——, an adult, about thirty years of age, and in good general health, came to my office complaining of a severe tooth-ache.

Placing him in a chair before the laryngoscope, and examining the part complained of most carefully, I could

[1] New York Medical Journal, January 18, 1890.

not detect the slightest evidence of swelling. To relieve the intense pain I injected, hypodermically, in the cellular tissue between the cheek and gum, opposite the left wisdom-tooth, about five drops of a four per cent. solution of cocaine. Almost immediate relief from pain was experienced, but in less than five minutes the entire left side of the face became enormously swollen, tense, and painful. As I sat watching the patient I could see the swelling rapidly increase, indeed it was about like watching the inflation of a toy balloon or a foot-ball, it was so plainly manifest. The inner surface of the cheek projected so far into the oral cavity as to render perfect closure of the mouth utterly impossible. So rapid and extreme was the swelling of the soft parts, that I concluded I had punctured one of the larger blood-vessels, thus permitting a free outflow of blood into the loose connective tissue of the cheek.

In the course of an hour the pain became so intense, and the tension so great, that I determined to relieve him by operative measures, so certain was I that the swelling and tension were due to the escape of blood, which I supposed had coagulated, and could in that condition be easily removed. He was therefore anæsthetized, and an incision made through the mucous membrane of the cheek and the underlying tissues sufficiently deep and long to permit the introduction of the index-finger, with which I examined every part of the interior of the cheek without finding any evidence of the presence of a large blood-clot. To say that I was surprised is putting it mildly, for not only was the cheek enormously swollen and tense, but semifluctuating to the touch. The slight hemorrhage from the small vessels along the edges of the cut tissues diminished appreciably, for a few moments, the swelling of the cheek, but shortly after the wound made by the knife had been closed, the tension and swelling became as marked as before the operation. The further treatment of the case consisted in the use of liq. plumbi subacetat. et opii, locally applied. At the end of four days the swelling had almost entirely disappeared, leaving the skin discolored, presenting the appearance usually seen when the integument has been bruised. There was with the local swelling no systemic disturbance, differing in this regard from a case I reported some time ago. It is probably true that the swelling of the cheek, in this case, was due to the paralyzing effect of the cocaine upon the vaso-motor nerves, causing thus a dilatation of the blood-vessels with consequent intense congestion. Having had this experience, I would not again inject a solution of cocaine (even a four per cent. solution) into loose areolar connective tissue, in the region of the face, without, at least, informing the patient of the possible result, and I am quite confident that if my patient had known, prior to the injection, what he subsequently learned about the peculiar effect of cocaine upon him, he would have objected to its use.

I consider the employment of a ten per cent. or fifteen per cent. solution of cocaine both unnecessary and hazardous for the production of local anæsthesia, such as is necessary for the painless removal of small tumors. Cocaine is an agent of great power and usefulness, but one which must be used with great caution.

Salol in Gonorrhœa. — Dr. Dreyfous, of Paris, has treated seven cases of gonorrhœa with salol. The doses varied from 5, 7, to 8 grammes. The discharge was quickly made less abundant. In a recent case, in which gonorrhœa appeared some time before seeking advice, Dr. Dreyfous obtained a complete cure in a few days. He has tested the effect of salol administered alone, and in other instances he has given it simultaneously with copaiba and cubebs in order to hasten the cure. He recommends the use of salol to surgeons who operate on the urinary organs. According to him it renders urine aseptic, which is thus innocuous when in contact with raw surfaces.

THE COMPLICATIONS AND SEQUELÆ OF INFLUENZA.[1]

By WM. H. DRAPER, M.D.,

NEW YORK.

I SHALL devote the few remarks which I have to make in this discussion to a brief consideration of the complications and sequelæ of the epidemic influenza. These complications and sequelæ may be described for the most part as exaggerated expressions, or a more or less protracted persistence of the ordinary symptoms of the disease. They are, therefore, like the symptoms, divisible into two principal varieties: First those which are included in the sensory-motor derangements which result from the effect of the materies morbi, whatever it may be, upon the cerebro-spinal system; and, secondly, those which illustrate the manifold and severe lesions which the disease determines in the mucous membranes and parenchymatous tissues. Sometimes the disease manifests itself mainly by its cerebro-spinal symptoms, and sometimes the catarrhal lesions constitute its prominent feature; but commonly it presents a combination of more or less profound derangement of nervous functions with varied forms of catarrhal and parenchymatous affections. In many respects epidemic influenza presents striking analogies to the other infectious fevers, and notably, perhaps, as has been repeatedly observed, to epidemic cerebro-spinal meningitis. In its sudden and often violent mode of onset, in the variety and occasional intensity of its nervous symptoms, in its irregular febrile movement, in its manifold lesions and in its marked tendency to relapse, it certainly often reminds us of this form of epidemic meningitis. All the symptoms suggest irritation of the cerebro-spinal axis, more or less severe, and it seems probable that the lesions of epidemic influenza, like those of epidemic meningitis, are determined by vaso-motor derangement.

I have said that the complications of epidemic influenza are, as a rule, only exaggerated expressions of its ordinary symptoms. To the chill, headache, and more or less severe malaise, which commonly characterize the attack, there may be added delirium, and in children convulsions; cases have been reported which, in their onset, have been mistaken for meningitis. In some instances the nervous shock manifests itself by giddiness and faintness, with an abrupt and inexplicable failure of mental and muscular power which may surprise the victims on the street or at their occupations, and compel instant capitulation to this subtle and insidious disease. The mental hebitude which, in varying degrees, is a common phenomenon, may even assume the features of melancholia, and cases of suicide have been recorded in this as in previous epidemics. The muscular paresis is often so extreme as to render patients quite helpless. The sensory disturbances are at first more or less generalized in the form of cutaneous hyperæsthesia, muscular pains, and soreness. Definite neuralgias in the distribution of important nerve-trunks, though occasionally observed at the outset of the disease, are, I think, more often consecutive phenomena. These neuralgias affect especially the cervico-occipital, the trigeminal, the intercostal, the lumbo-abdominal, and the sciatic distributions. They often are intermittent, like the neuralgias of malarial origin, but without any regular periodicity. They are sometimes accompanied by exquisite tenderness along the course of the affected nerve, and are much aggravated by movement, two features which seem to indicate that the lesion which determines them is a perineuritis. A few cases have fallen under my notice in which the symptoms of an interstitial, and possibly even of a parenchymatous neuritis were present. In one case of this description, which occurred during convalescence from catarrhal pneumonia, the musculo-spiral and median nerves of the left arm were involved. Paralysis of the flexors and extensors of the forearm fol-

[1] Remarks made before the New York Academy of Medicine, February 6, 1890.

lowed, with considerable atrophy. A paretic condition of the limbs, following brachial and sciatic neuralgias, without ostensible atrophy, has been a common observation. I have not seen any trophic disturbances in the skin excepting in connection with the trigeminal neuralgias; conjunctival congestion, and herpetic eruptions about the mouth have been frequently observed. As a rule, I think the neuralgias occurring as sequelæ of influenza have been confined to the distribution of single nerve-trunks, to a branch of the trigeminal, generally the supra-orbital, of the brachial or sciatic plexus, or to an intercostal nerve on one side, though I have seen a number of cases of double sciatica, and one of multiple neuritis, which I believe to have been of influenzal origin.

A conspicuous feature of the nervous phenomena of influenza has been their protracted duration. This has been manifested frequently in the persistence of the neuralgias, and especially in a continuance for some weeks of muscular weakness, fatigue on slight exertion, mental depression, in a feeble and rapid pulse, and generally in a slow and halting recovery.

The complications of the catarrhal form have presented themselves most frequently in the respiratory tract. Cases of acute pharyngitis with intense congestion of the mucous membrane, extending sometimes into the Eustachian tube and causing otitis media, have not been uncommon. Laryngitis and tracheitis, accompanied by a paroxysmal, pertussis-like cough, have also been observed, complicated in such a way with the nervous symptoms of influenza as to leave no doubt of their specific origin. But the most serious and important complications of the catarrhal form of the disease have been bronchitis, broncho pneumonia, pleurisy, and pleuro-pneumonia. The peculiar feature of the bronchitis, in my experience, is that it has often been confined to one lung or to a portion of one lung. It has not usually been accompanied by much expectoration, but rather by feeble respiration with only occasional moist or dry râles on forced inspiration. The development of a lobular pneumonia from this condition has generally been slow, and the signs of consolidation often difficult to determine after the subjective signs have suggested its existence. A localized pleurisy is sometimes superadded to this condition.

In the cases of lobar pneumonia the onset of the disease has, I think, been as characteristic in its suddenness, and the progress of the consolidation has been as rapid, as is ordinarily observed in croupous-pneumonia. It has seemed to me that the pleuritic element in the severe cases has been unusually pronounced, the pain intense and widely distributed, and the tenderness of the costal and abdominal walls extreme. I have also noticed that even in cases of large pulmonary lesion the vital signs did not present the characteristic features which usually prevail in ordinary lobar pneumonia. The range of the temperature has not, as a rule, been so high and the pulse-respiration ratio has been more irregular. Defervescence has, in my observation, seemed to occur earlier and the resolution of the lesion to be slower. The slow resolution has been due in some cases to the pleuritic complication which, as I have before remarked, has been unusually severe.

The complicating lesions in the gastro-intestinal canal have not, in my experience, been common, but they have occurred with sufficient frequency in this and former epidemics of influenza to justify the statement that the disease may spend its force in this direction, and without the appearance of the usual pulmonary symptoms. In some instances the gastro-intestinal derangement has been so severe as to suggest the existence of typhoid fever, especially in the exceptional cases where the fever has continued for a week or longer, in connection with abdominal pain and tenderness, with gurgling in the ileo-cæcal region. In two such cases which I have seen the stools contained blood.

I have not observed any complications affecting the genito-urinary tract. Cases of cystitis and of acute uterine catarrh have been described, accompanied by the general constitutional disturbances which characterize the grip, and though one is too prone, perhaps, during the prevalence of such a disease to multiply its manifestations, it is not improbable that the morbid influence complicates, if it does not determine, a great variety of structural derangements.

Many observers in this and in former epidemics have described various forms of erythema complicating influenza. I have several times observed herpetic lesions, especially about the head and face, with œdema of the lids, associated with neuralgia, but I have probably overlooked the scarlatiniform eruption which has been reported in many cases. The occurrence of cutaneous, and even of arthritic, lesions in a disease which often exhibits such remarkable cerebral and peripheral nerve-irritation is certainly to be expected.

In conclusion, I have only to note the remarkable frequency of relapses in this disease, and also the fact, especially noted in hospital patients, that the relapse is more severe and accompanied by more serious lesions than the original attack. The tendency to relapse, while frequently the result of imprudence, has often been observed in those who have been carefully guarded against exertion or exposure.

From this brief and imperfect sketch of the complications and sequelæ of epidemic influenza it seems evident that the determining cause of the disease, whatever it may be, is one which spends its force, primarily and directly, upon the nervous system. Its most serious results have, as a rule, been observed in persons of advanced years, and in those who were enfeebled by previous disease or intemperate habits.

The relative mortality of the malady has, to be sure, not been large, but when we consider, apart from the mortality it has caused, the vast sum of human energy that it has destroyed, and the check that it has everywhere put upon the wheels of human industry, its effects have indeed been appalling.

Progress of Medical Science.

The Action of Remedies on Gonococci.—Dr. Friedheim, of Leipzig, has published an elaborate paper on this subject, a *résumé* of which appears in the *Provincial Medical Journal*, January 1, 1890. He had an exceptionally large material at his disposal, consisting of twelve hundred cases, in which he tried a great number of different remedies. For these experiments all fresh and all those cases which did not improve under previous treatment had been selected. Each injection was kept in the urethra for three minutes, the injections were repeated three times a day, and the quantity injected each time amounted to 500 minims. A trace of discharge was taken out from the depth of the urethra, by the aid of a platina loop, and examined microscopically on the presence and number of gonococci. The effect of the different remedies is as follows: Hydrarg. formamid. in a solution of 1 in 1,000 to 10,000 has a powerful germicidal action, but this is combined with signs of irritation in the urethra, dysuria, increased secretion; calomel, in a ten per cent. mixture, with fifteen grains of chloride of sodium, does not irritate so much, but also the germicidal action is less pronounced; salicylate of mercury, 1 in 270, with 1 chloride of soda, completely destroys the tocci, without much concomitant irritation; perchloride of mercury, even in solutions of 1 in 20,000, causes pains, and the antibacillary action is not great. Zinc, tannin, and lead solutions, in the usual concentrations, had no influence whatever on the cocci; subnitrate and salicylate of bismuth are not at all convenient for the treatment of acute gonorrhœa; it must be acknowledged that they lessen and liquefy the discharge, but they do not destroy the germs. Permanganate of potassium, in more concentrated solutions, kills the cocci, but highly irritates

the mucous membrane, the discharge becomes thinner, and the number of pus corpuscles decreases under the influence of weaker solutions. The following remedies were either found insufficient, or they acted on the cocci only when applied in such a high state of concentration that violent irritation of the urethral membrane was the immediate consequence: Nitric acid, 1 in 1,000; pyrogallic acid, 4 in 100; chloroform water, iodoform oil, one per cent. creasote, camomile tea, boracic acid, acetate of alum, antipyrin, resorcin, salicylate of soda, lime-water, naphthol, sozojodol-potassium-sodium-zinc, creolin (1 in 100), fluor-silicate of sodium, chloroborate of sodium, borax, Rotter's solution, sulphate and tartrate of thallium. The author subsequently recommends the nitrate-of-silver treatment of acute gonorrhœa, according to the following method: In acute gonorrhœa injections of a solution of nitrate of silver, 1 in 2,000 or 1 in 4,000 are at once installed, and repeated four to six times a day. The discharge, first abundant, becomes thinner after four days, and the number of gonococci decreases. The injections are now reduced to two or three a day, and soon replaced by astringent injections of zinc, tannic acid, or boracic acid. Secretion soon ceases, nearly completely. One injection of nitrate of silver is continued for many months. Strict diet is necessary at the commencement, but ordinary style of living may be enjoyed after some weeks. With delicate patients the number and concentration of the injections of nitrate of silver may be reduced, or injections of antipyrine or boracic acid are used, just before or immediately after the injections. Warm baths, calming suppositories, are frequently indicated. If nitrate of silver is not borne at all, it ought to be replaced by salicylate of mercury, chloroborate of sodium, thallin, etc. If this application is also inefficacious, the administration of internal remedies has to be resorted to. Of all kinds of internal medications for the said malady, he only believes in the benefit derived from large doses of copaiba balsam (up to twelve capsules per day, each containing ten grains of the balsam).

Henoch on Diphtheria.—Professor Henoch, the distinguished Berlin authority, has recently published his experience in one hundred and ninety-two cases of true diphtheria. In the February number of the *American Journal of the Medical Sciences* this paper is thus referred to: "Scarlatinal diphtheria he considers an affection entirely distinct from true diphtheria. There are certainly instances in which scarlatina and diphtheria are combined, but either the former has appeared in cases of diphtheria well under way, or in the stage of decline; or the latter affection has developed in the later stages of scarlatina; certainly after the third or fourth day. Only in such cases of scarlatina does diphtheritic paralysis appear. To distinguish diphtheria from angina lacunaris is often not possible until after continued observation. In some instances, indeed, it is impossible, namely, in those in which there occurs a deposition of fibrin in addition to the collection of pus in the depressions of the tonsils. In these cases the bacteriological examination would give certainty, if only we knew more accurately the nature of the bacillus and of the pathological anatomy of the affection. Diphtheria can, indeed, only be recognized positively when all or several of the cardinal symptoms are united; such as bilateral distribution of the membrane in the throat; involvement of the soft palate, uvula, etc.; albuminuria; involvement of the nasal cavities; contagiousness. Swelling of the glands and fever may appear in simple angina as well. In 110 of the cases the membrane was confined to the pharynx; in 82 it spread to the larynx, or still further down. In 12 of these latter, tracheotomy was not performed on account of various contra-indications, while of the remaining 70 on whom the operation was performed, 9 recovered—a percentage of 13. Many of the cases died of pneumonia, bronchitis, collapse, or heart failure, after the operation had apparently had a good result. Henoch attributes this low percentage of recoveries not to a severe form of the disease, but to the fact that more than half of the children were already suffering from different constitutional diseases, others were very poorly nourished, and many were quite young; while, in addition to these factors, the hygiene of the hospital was extremely bad. One great source of error in statistics is that writers include in them the cases of true croup, and thus greatly increase the apparent number of recoveries. Henoch has seen 36 cases of croup, of which 24 (66 per cent.) recovered after tracheotomy. Of the 110 cases of pharyngeal diphtheria, 32 died—a favorable percentage. The degree of fever proves nothing as to the severity of diphtheria. The swelling of the glands usually undergoes resolution; it is seldom that suppuration takes place as in scarlatina. The diphtheritic membrane is of prognostic significance. Membrane on the hard palate is an exceedingly unfavorable sign, while involvement of the cheeks, tongue, lips, genitals, and anus also makes the prognosis bad. On the other hand, the spread of the membrane to the nose is not especially unfavorable even in bad cases. Diphtheritic nephritis appears from the third to the fifth day, and is characterized by tube-casts, epithelium, and a few red blood-cells; in contra-distinction to scarlatina, in which the number of blood-cells is large. The appearance of albumin not until a later period of the disease is very unusual, and cannot be affirmed unless the presence of scarlatina or the persistence of an early albuminuria can be absolutely excluded. Henoch has seen this late nephritis but twice. Œdema is much rarer than in scarlatina; uræmia is very exceptional; affection of the joints has come to his observation but once. A croupy cough and stridor form no indications whatever for tracheotomy. The author has tried various methods of treatment, and found them all useless in severe cases."

Periodic Gastrorrhœa.—Dr. Steinberg gives an account of a remarkable case of periodic gastrorrhœa occurring in a military officer, aged forty-five. The patient was suddenly seized with a series of attacks of violent vomiting coming on every forty to sixty minutes, each attack being preceded by severe nausea and headache, which symptoms disappeared immediately after the contents of the stomach had been rejected. The vomit consisted of a greenish watery fluid, containing 0.17 to 0.21 per cent. of free hydrochloric acid and a very little mucus, but no traces of food. There was no abdominal pain or tenderness. On inquiry it was found that the patient had been subject to attacks of this nature at long intervals for several years. There were signs of lesion of the posterior columns of the cord, but these were limited to Westphal's and Romberg's phenomena, and there was no ataxy; thus the diagnosis was made of periodic gastrorrhœa in a tabetic subject rather than that of gastric crisis in an ataxic subject.—*The British Medical Journal.*

Large Doses of Arsenic in Lymphadenoma.—At a late discussion at the Paris Academy of Medicine, M. Reclus read notes on eight cases of cervical lymphadenoma treated by large doses of arsenic. The initial dose given was ten drops of Fowler's solution, which was given daily, gradually increased; interstitial injections were also given every two days. The solution was mixed with an equal quantity of water, and the dose gradually increased to twenty drops. Three patients thus treated were cured; three died rapidly; with the two others the treatment had to be discontinued. M. Berger stated that he had often seen in Dolbeau's wards examples of relapse after removing glands, and personally had always found internal arsenical treatment joined to interstitial injections satisfactory. In three cases, one exhibited great improvement, the other two patients died. M. Terrier is also in favor of arsenical treatment of lymphadenoma when limited to internal treatment. He condemns the practice of interstitial injections, and prefers making an incision, which he deems necessary in order to be certain of arriving at a true diagnosis.—*The British Medical Journal.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, March 1, 1890.

THE SYMPTOMS OF DISEASE OF THE PANCREAS.

CONSIDERABLE interest has been excited in the subject of diseases and injuries of the pancreas by the contributions of Senn and of Fitz in this country, and by those of Lancereaux, Minkowski, and von Mering, and others in Europe. The pancreas is an organ which is rarely subject to organic disease, or to injury; nevertheless, it is not entirely free from ills, and it is likely that minor and functional disorders are not so very rare.

In a recent review of this subject by M. F. de Grandmaison (*Gazette des Hopitaux*, January 4, 1890), the following diseases are said to affect the pancreas: Acute and chronic pancreatitis, abscess, lithiasis, apoplexies, and tumors, including cysts. To this may be added lipomatosis, degenerative atrophies, disorders secondary to compression, and functional affections.

Of these somewhat numerous affections, it is only chronic pancreatitis, lithiasis, tumors, and perhaps functional or secondary disorders from compression that can be at present recognized. All the acute disorders, except perhaps abscess, are practically unrecognizable. The cardinal symptoms of pancreatic disease are stearrhœa, glycosuria, phenomena of compression, and rapid emaciation.

The stearrhœa was first noted as a symptom of impaired function of the pancreas by Cl. Bernard, who produced it by experiments on animals. It has also been noted clinically by Kuntzmann, Bright, Unckel, Ancelet, and others. Sometimes there is associated with it fatty vomiting. The fatty stools persist even when fat has been withdrawn from the food. However, stearrhœa may be absent in severe pancreatic disease, and it is not by any means a pathognomonic sign.

Glycosuria has been produced experimentally in animals by destruction or injury of the pancreas, and according to Lancereaux and his pupil Lapierre, it may be an evidence of pancreatic disease. M. Lancereaux, indeed, asserts that there are three forms of diabetes, viz.: (1) The nervous, (2) that occurring in the obese, and (3) the emaciative form, the latter being due to chronic pancreatitis or pancreatic lithiasis.

The nervous form of diabetes results from emotional shocks, traumatism, combined with lithæmic states, and it is usually temporary. It is, in fact, a glycosuria of symptomatic character only. The diabetes of the obese is the more common form; it comes on slowly and progresses slowly.

The diabetes with emaciation comes on suddenly, the patients rapidly lose weight, the amount of sugar in the urine is large (50 to 85 grammes daily), and the duration of the disease is not long, the patients dying usually of tuberculosis. The skin is rough and dry, but the boils and carbuncles which occur in the diabetes of the fat are not observed here.

The symptoms of pancreatic disease due to compression are chiefly those resulting from compression of the bile duct. The gall-bladder is distended, the liver remaining of normal size, and icterus gradually develops.

The general symptoms in organic pancreatic disease are those of cachexia and great emaciation. Often there is epigastric pain and intestinal dyspepsia, with much flatulence and loose stools.

As for the special significance of the above symptoms we are still much in the dark. Stearrhœa, we are told, is rare in pancreatic lithiasis, but more common in primary cancer of the head of the pancreas.

Diabetes with rapid emaciation, if indicative of any pancreatic disease, points rather to lithiasis and secondary pancreatic inflammation and degeneration.

THE CASE OF DR. MARY A. DIXON JONES.

THE case of Dr. Mary A. Dixon Jones, of Brooklyn, to which attention has been previously directed, has excited a great deal of interest in professional circles pending the issues in a trial for manslaughter, charged to the unfortunate termination of a capital operation for the removal of a diseased ovary. The original indictment of the Grand Jury of Kings County was founded upon a series of baseless charges, persistently reiterated in a Brooklyn journal of large circulation, bearing upon unskilful treatment of the case, wilful and culpable neglect of the ordinary obligations of humanity, and dark, mysterious, and even murderous doings in the management of the hospital with which she is connected. All these allegations, absurd as they were, inflamed the public mind against the doctor, almost ruining a hitherto untarnished reputation. When, however, the case came to trial the real facts were brought out, and an unqualified and triumphant acquittal was the result.

At the opening of the trial the prosecution abandoned its charge that the operation had been improperly performed, and consented to the discharge of her son, Dr. Charles Dixon Jones, who had been conjointedly indicted. An attempt was then made to prove that the patient was compelled to leave the hospital in a dying condition, from septic peritonitis, be drawn to her home over a rough road, on a stormy night, and that death ensued in consequence thereof within a few hours afterward. Testimony offered on these point by the friendss of the dead patient was clearly prejudiced, and in essential particulars was entirely unsupported by facts. The latter, as presented in the defence, showed that the operation had been urgently demanded by the patient; that it had been skilfully performed, under strict antiseptic precautions; that septic peritonitis ensued, in spite of every care to the contrary; that the patient and her friends demanded removal from the hospital; that Dr. Jones protested, on account of the danger attending such transfer, and that when compelled to accede to the request volunteered to diminish the risk

by accompanying the patient and watching her condition during the ride. The influence of this journey in producing death was embodied in any hypothetical question submitted to the surgical experts. Those on the side of the prosecution replied in the affirmative, and, strangely, the one most positive in his answer was he who had no experience in surgical cases. The answer on the part of the defence was somewhat qualified, although none denied that the removal might not have hastened death. It was proven, however, the carriage trip did not show any immediate bad results.

Even the defendant herself was willing to admit that such a journey was very likely to be attended with bad results, but that she was, under the circumstances, powerless to prevent it.

The learned judge, in ably and impartially charging the jury, accentuated these points, and the unanimous verdict of not guilty was rendered accordingly.

The lessons of this case are not few and unimportant. We have here an instance of indictment against a reputable physician, based upon mere public clamor, originating in anonymous and unfounded charges in a daily paper. At the trial we find, when all the facts were sifted, that, instead of being a fraud, an unskilful physician, and little short of a murderess, the defendant at the worst was guilty of a simple error of judgment in consenting to the transfer.

A discussion of the medico-legal points in this remarkable case has a far-reaching significance as relating to similar ones which may occur in the practice of any physician or surgeon. Although, fortunately and very properly, there was a unanimous verdict for the defendant, the aspect of the case would have been serious indeed if a contrary decision had been given by the jury. The fact that the question was raised at all showed how closely the chances were balanced against the establishment of a dangerous precedent. Had the verdict been against the defendant, a death-blow would have been aimed at progressive surgery. If the surgeon, assuming, as he necessarily does, grave responsibilities, should be held accountable for errors of professional judgment, thousands of operations which are now undertaken for the saving of human lives would be abandoned. The desperate cases, which would require desperate remedies, would necessarily die unrelieved, in fear of suits for malpractice, if not for actual manslaughter. Even the commoner injuries would be hesitatingly treated, in fear of legal consequences; and the maimed, the halt, and the blind would be present everywhere to mock the high and noble resources of our art. As it is, we congratulate Dr. Jones, and the profession at large, that we again touch solid ground, and are enabled to vindicate our rights for protection in the freest possible use of individual judgment in the treatment of our cases.

Dr. Jones, in the trying ordeal to which she was subjected, not only showed herself to be a skilful surgeon, but an admirable witness for the profession, in proving its resources, emphasizing its achievements, and upholding its dignity.

A PROPOSED NEW LUNACY LAW.

There is now before the Legislature a bill which proposes greatly to modify the present statutes regarding the commitment and care of the insane. This bill passed the Legislature at its last session, but owing to the sharp protest of the Neurological Society and of several physicians and lawyers in this city it failed to get the Governor's signature.

The bill has now undergone careful revision by a committee of the New York Neurological Society, working in conjunction with the late Commissioner of Lunacy, Dr. Stephen Smith. As modified it contains a number of improvements in the regulations for committing and caring for the insane. The mode of committal is not greatly changed, but a form is given which must be filled up by the examining physicians, and this form will give much more explicit information regarding the symptoms of the case than was obtained by the old plan.

One recommendation made by the committee of the Neurological Society ought to be added to the bill. It is to the effect that there should be a section in the law permitting any higher justice, upon application from any patient in an asylum, to appoint at his discretion a commission of two or three physicians to examine the patient as to his mental condition, and upon receiving their report favorable thereto, to discharge him from the custody of the asylum. By the Laws of 1889, chap. 283, § 22, the State Commission in Lunacy is empowered to make such regulations as to the correspondence of patients as would insure the proper carrying out of this law.

By this means the committed patients would always have a means of securing an investigation of their case.

PHYSICIANS DID NOT CONCEAL A MURDER.

Our attention has been called to an item, copied in the Record from the *Times*, in which it was charged that Drs. MacNichol and Williamson, of Westchester, N. Y., under the influence of a secret order of Irishmen, had given a certificate that a man, supposed to have been murdered, had died of acute congestion and œdema of the lungs, when it was subsequently shown that there was a bullet-wound of the peritoneum. This is flatly contradicted by Dr. MacNichol in an explanatory letter to the Record, from which we willingly quote, in justice to him, giving due prominence to his vindication. He writes:

"I refrained at that date from giving a contradiction to the *Times*, because I calmly awaited vindication in the courts, and thus far I have been fully gratified. At the preliminary hearing the Grand Jury passed over the various degrees of murder, and indicted for manslaughter in the lowest degree, which verdict, without trial, permits of one year's imprisonment; the bail being fixed at $1,000.

"The above decision was given, notwithstanding the unscrupulous efforts of a self-advertising combination, which spread the *Times*' article, its own manufacture, over Westchester County, and appealed to the vilest passions of race and religion in order to procure an indictment for murder in the first degree. This action could not but have exercised a certain amount of influence, but happily not sufficient to make men forget the principles of equity.

"The above rendering of the Grand Jury was given but a line in an obscure corner of the *Times*, which had devoted columns to an outrageous attack. This I deem sufficient answer to the first charge; because, if the

Grand Jury did not indict for murder, by what authority is it said that physicians concealed a murder?

"On December 20th the family of the injured man sent their attendant physician to me, strongly urging me to see their son in consultation. Having previous engagements I was forced to decline, but one of my own family, through sympathy with the afflicted ones, lending her entreaties to theirs, I consented to forego other and more lucrative appointments, and met Dr. Williamson in consultation at the house of the Rusks.

"My connection with the case, therefore, was due to the influence of no secret society of Irishmen, as stated, but solely to the urgent solicitations of the Rusk family and their friends. Here, in passing, allow me to say, that I belong to no societies other than medical.

"The result of the first autopsy, without going into details previous to the trial, verified the diagnosis made by me on my first visit, viz., that the wound was a non-penetrating one; that the intestines had not been perforated; that peritonitis did not exist; but that the immediate cause of death had been acute congestion and œdema of the lungs.

"Upon the findings of the second autopsy, made almost weeks after death by 'the well known pathologist' whose street and house-number appear so innocently linked together in the public press, office hours alone omitted, and who proclaims post-mortem wounds to be bullet-wounds, etc., a stronger light shall be cast on the day of trial than will be considered favorable to their peculiar form of truth and beauty.

"It might interest your readers to learn that a third autopsy, the body having been buried nearly two months, has just been made. A newspaper of the place, which we hand you, commenting on this action, says: 'It seems that the prosecution must feel the weakness of their case from the testimony adduced before the Grand Jury last week.' And again: 'The men who were the instigators of such notoriety are commencing to feel that their pet schemes are about to be blasted at the trial of the case, and are seeking for some more manufactured testimony to help them out of their difficulty.'"

News of the Week.

Searching a Medical College for Anatomical Material.—The Tennessee Medical College has lately been subjected to several searches by officers armed with search-warrants for the discovery of bodies alleged to be under dissection. Becoming tired of the annoyance, the college has applied for an injunction against the justices issuing any more search-warrants, on the ground, among others, that such warrants would not apply to dead bodies as "property." The college purposes to see if the private apartments of the institution are to be thrown open to the curious gaze of the indiscriminate public.—*Boston Medical and Surgical Journal.*

The Definition of a Homœopath.—The Medical Board of Ward's Island Hospital have adopted the following resolution: "*Resolved*, That in the opinion of this board the only requirement as to belief and practice of a physician should be as follows: That in common with other existing associations which have for their object investigations and other labors which may contribute to the promotion of medical science, we hereby declare that we firmly believe the principle *similia similibus curantur* to contribute the best general guide in the selection of remedies, and that we fully intend to carry out this principle to the best of our ability; yet this belief should not deter us from recognizing and making use of the results of any experience, and we shall exercise and defend the inviolable right of every educated physician to make use of any established principle in medical science, or any therapeutic fact founded on experiments, and verified by experience, so far as in his individual judgment they shall tend to promote the welfare of those under his professional care."

Just now, says the *Memphis Medical Monthly*, people are forcibly reminded of Tennyson's pathetic lines: "A sneeze that is all a sneeze may be met and fought out right, but a sneeze that is part of the grip is a harder matter to fight."

Normal Weight of Man.—A rule to determine the normal weight of man is as follows: A man should weigh just as many kilograms as he measures centimetres in height after deducting one metre. A man who measures in height 1 metre 80 centimetres (5 ft. 11 in.) should weigh 80 kilograms, or about 160 pounds. The rule is both ingenious and approximately correct.

A Doctor Sues a Druggist.—Dr. Samuel J. Leggett, a Philadelphia physician, wrote the following prescription: "Potass. bromide, two drachms; tincture aconite root, twelve drops; sweet spirits of nitre, two drachms; sulphate of morphia, one and one-half grain; peppermint water, half-ounce; simple syrup sufficient to make three ounces." Of this the patient was directed to take two teaspoonfuls every two hours, in water. This was handed to the druggist by the patient, but the druggist refused to put it up, saying that it would poison her by forming an insoluble hydrobromate. Dr. Leggett brings suit for $20,000 against the druggist, for injury to character and reputation; asserting that the prescription was a proper one.

Dr. Bissett, surgeon of the steamship Bolivia, which arrived on February 22d, from Mediterranean ports, died on February 13th, of influenza, and was buried at sea. He was a native of Moray, Scotland, and was twenty-eight years of age.

Dr. C. C. Perry, formerly connected with the Department of Agriculture in Washington, and well known as a botanist and physician, died on February 20th, in Davenport, Ia. He was sixty-seven years of age.

The Influenza is slowly making its way down through Mexico and Yucatan to the Central American States. It has not yet made its appearance in the West India Islands.

The Centralblatt für Nervenheilkunde has ceased to exist, the cause of its death being the retirement of the editor, Dr. Erlenmeyer.

A Hospital for Sick and Lame Animals has been established in Calcutta, and it is proposed to open in connection with it a veterinary school. A similar institution has existed for some time in Bombay.

A Ton and a Quarter of Bromides are annually consumed by the patients of the National Hospital for the Paralyzed and Epileptic in London.

The Paris Academy of Medicine, after a long and stormy debate, has adopted the following resolution regarding tuberculosis: "Tuberculosis is a parasitic and contagious disease. The microbic agent of the contagion especially resides in the dust produced by the dried sputa of phthisical subjects, and by the pus of tuberculous wounds. The safest measure for preventing contagion consists, therefore, in destroying these sputa and pus, before their desiccation, by means of boiling water or by fire. The parasite is also occasionally found in the milk of tuberculous cows; it is therefore prudent not to use any milk until it has been boiled. The Academy calls the attention of competent authorities to the dangers arising from the presence of tuberculous subjects in lycées, barracks, state offices, workshops, etc."

The Monad of Influenza.—Professor Klebs, of Zurich (*Centralbl. f. Bakter.*, vii., No. 5, *The Lancet*), gives the results of his examination of the blood in cases of influenza. He finds a large number of highly refractile, mobile bodies, in size, form, and motility resembling bodies which he has met with in pernicious anæmia, but in far less quantity. Moreover, no microcytes, such as occur in the latter disease, were to be seen. In a fatal case of influenza some blood was removed from the heart, with every precaution to avoid contamination, and the "monads" were detected therein; they varied somewhat in size, being oval in shape, and not only had vibratory movement, but were also capable of locomotion. They were often attached to the margin or embedded in the substance of the blood-corpuscles. The organisms were distinctly flagellated, and in stained preparations their intimate connection with the corpuscles could be plainly shown. Provisionally, Professor Klebs would assign them a place among the Rhizomastigma of the Monadineæ, according to Bütschli's classification of these protozoal forms. The professor remarks that in other diseases in which similar hæmatozoa have been discovered, as ague and pernicious anæmia, there is a tendency to intermittency in the type of fever; and since influenza shows a like tendency—commonly styled relapse—he thinks it quite possible that such "relapse" is associated with stages in the development of the micro-organism.

The Society for Instruction in First Aid to the Injured has just issued its regular report for 1889. This organization has been in existence since 1882, and has accomplished, first and last, much good. The latest report of the Society shows that, during 1889, no less than twenty courses of lectures, pay and free, were given to members of the Police Department, to railroad employees, working girls' clubs, and others.

The Ninth German Congress of Internal Medicine meets in Vienna April 15–18, under the presidency of Professor Nothnagel. The treatment of empyema and of chronic nephritis are among the subjects to be discussed.

The Physicians of the State of Virginia are annually taxed from $30,000 to $35,000 for the privilege of pursuing their daily avocations. The tax is in the form of an annual license fee.

Doctors and the Notification of Infectious Diseases.—The City Council of Chester, Pa., months ago passed an ordinance requiring all doctors to make a monthly report of births and deaths, fixing a penalty of $50 for each failure. The City Clerk reports not one of the thirty doctors complying with the ordinance.

France and the International Congress.—M. Henri Huchard (*Revue Générale de Clinique et de Thérapeutique*), in noting the receipt of invitations to take part in the Congress to be held at Berlin in August, says that many of his *confrères* have replied in the negative to the question: "Ought we to take part in this congress?" For his own part he declares that French physicians may and ought to participate in it, and he replies to those who justify their abstention from patriotic motives by an appeal to France to take her scientific rank among other nations. He does not know what reception will be awarded them, but he is persuaded that France should make her presence and her scientific labors known in an *international* congress.

Grave-robbing by Kentucky Physicians.—A startling story comes from Louisville, Ky., to the effect that two physicians of that city have been caught robbing graves. A negro who was in their company was killed. We trust that the story is not true.

The Cause of Death by Chloroform.—In the *Medical News* of February 22, 1890, Drs. H. C. Wood and H. A. Hare publish an article in which they strongly antagonize the conclusions of the Hyderabad commission as to the cause of death from chloroform. They assert that numerous experiments upon dogs, made in past years, have shown conclusively that chloroform may cause sudden death by paralyzing the heart, and maintain the view that when chloroform is given to the lower animals in a very dilute form, and gradually pushed, it causes, by its action upon the nerve-centres, a paralytic relaxation of the muscles, and at last death by paralysis of the respiratory centres; but that, when it is administered freely in concentrated vapor by inhalation, or when it is injected in sufficient amount into the jugular vein, it kills by a paralytic arrest of the heart, the viscus stopping suddenly in its beat, and being found after death relaxed and incapable of reacting to stimuli. It has, they say, generally been believed that the danger from cardiac arrest by chloroform increases in direct ratio with the rapidity of administration; but that in animals, as well as in man, cardiac arrest sometimes occurs almost at once on the inhalation of the anæsthetic in small amounts; or, in other words, that comparatively small amounts of chloroform have at times caused death by syncope, through direct action upon the heart. They further assert that the evidence of the Hyderabad commission is all negative, and that positive evidence, even in small amount, quite counteracts it. The death of half a dozen American dogs by cardiac paralysis proves more than the death of four hundred pariah dogs by respiratory paralysis.

Another Death from Ether.—Dr. W. F. Westmoreland, of Atlanta, Ga., had a patient die from the effects of ether, while operating for fistula in ano, about ten days ago. He will give a detailed account of it in our next issue.

Medical Practitioners in Germany.—The number of medical practitioners is increasing at a rate quite disproportionate to the growth of the population. In 1889 the total number of doctors in the German Empire was 18,467, as against 17,690 in 1888, and 16,864 in 1887. The increase in 1889, as compared with the previous year, was at the rate of 4.4 per cent.—about five times that of the general population. The increase in the number of legally qualified dentists was still more remarkable, there having been 659 in 1889, as against 570 in 1888, and 514 in 1887, showing a rate of increase last year of not less than 15.6 per cent.

The late Professor Botkin.—It has been decided to honor the memory of the late Professor Botkin in the way which he himself would no doubt have chosen. A home for destitute medical men and for their widows and orphans is to be established in St. Petersburg; it will be called the *Botkin-Haus*.

A Medical Association in Chili.—Steps are being taken to organize a Medical Association in Chili. It is intended to include all the medical practitioners in the country. The object of the Association is "to give help to all members of the profession or to their families as often as they are in need of it." It has also been decided to form a Medical Association in Cuba.

Anecdote of Sir William Gull.—A correspondent of the *London Times* relates the following anecdote, which shows that Sir William Gull possessed a kindliness of heart only rarely met with in this money-getting age: "Some years ago a gentleman, whose failing health was coincident with failing fortune, consulted Gull. For a while the remedies were of use, but one day the patient presented himself looking so much worse that Sir William had to seek for a special cause. The explanation was adequate: 'I have been obliged to call my creditors together;' whereupon the great physician wrote a cheque for all past fees—about thirty guineas—and, putting it into his patient's hands with the other prescription, said simply: 'Perhaps that will help you more than the medicine to-day, but pray take them both.'"

What Can be Done in a Great Hospital.—The *Wallace Free Press*, Idaho, says: "Wesley Everett, who went to Bellevue Hospital, New York, recently, to have an ovarian tumor taken from his side, writes from that institution to his brother Frank, here, that he is feeling first rate since the operation was performed, and expects to be able to travel in a short time."

The Kings County Medical Association held their monthly meeting in Brooklyn, on Friday evening the 14th inst. Dr. Edward R. Squibb, the retiring President, read an elaborate paper on "The Approaching Revision of the United States Pharmacopœia." The following gentlemen were admitted to membership: Dr. A. B. Callender, Dr. Nelson L. North, Dr. Clarence Thwing, and Dr. Jonathan Wright. Drs. B. W. Waterman and J. del Risco were proposed for election. A resolution of esteem for ex President Squibb was presented by the President elect, Dr. Wm. McCullom, and unanimously adopted.

A New Hospital has just been completed at Bayonne, N. J. It contains about forty beds, and is well equipped with all modern conveniences.

Doctor's Signs.—In Paris, it has long been the habit of first-class physicians not to allow the slightest kind of publicity; this they carry to such an extent that it is difficult to find them, even if you know the street and number where they live, as they never put the slightest kind of a name-plate at the street door, nor on the door of their apartments. In the poor quarters of Paris, is sometimes seen a sign saying, *Docteur-Médecin*, but this is all; the name of the doctor is not put out, only the indication that a medical doctor lives in the house. This class of practitioner is understood to be of the cheap order, or one whose fees are small. What is curious in Paris is, that a man's name is never, in any class of physicians, displayed on a sign.—Correspondence of *Meaical Times and Register*.

Boston Cars and Boston Sewers.—W. R. Nichols, of Boston, found more than twice as much deadly carbonic acid gas in the air of passenger cars than in the Berkeley Street sewer.

The County Medical Society Vindicated.—Three suits for damages which Dr. Charles F. Kreizer had brought against the counsel and agent of the Medical Society of the County of New York, have been discontinued at the request of the plaintiff. Two of these actions—for false imprisonment—were brought in the Supreme Court, and one for malicious prosecution was brought in the Superior Court, and in them Dr. Kreizer sought an aggregate of $30,000 damages. Dr. Kreizer was arrested upon a charge of felony under the Medical act, in advertising under the false name of Kriger. He was indicted on this charge, but claimed that he did not intentionally use the false name, and that it was a misprint which, after vainly endeavoring to correct, he finally accepted. The Society gave him the benefit of the doubt, and consented to the dismissal of the indictment, whereupon Dr. Kreizer brought his suit.

A Malpractice Suit, resulting in the unsuccessful attempt of two lawyers to cowhide a medical editor, has been the sensation in medico-legal circles in Cincinnati recently.

Reviews and Notices of Books.

A Handbook of Diseases of Women, Including Diseases of the Bladder and Urethra. By Dr. F. Winckel. American edition, edited by Dr. Theophilus Parvin, M.D., Philadelphia. 8vo, pp. 766. Philadelphia: P. Blakiston, Son & Co. 1889.

The work of translation has been done by J. H. Williamson, of Allegheny, Pa., in a creditable manner. Winckel's work has met with a favorable reception on both sides of the Atlantic, and the American edition has already become a favorite with both practitioners and students. As is the case with most foreign treatises, the description of the diseases of each organ is preceded by an account of its embryological development. Etiology therefore receives its logical place, and there results a systematic explanation of each malady. A most admirable and elaborate table of contents, and a full index, render the book an easy one to use. It is complete and concise. It is out of place here to attempt to combat any of the author's individual ideas, as among gynecologists there often exists the widest divergence of ideas. But we have no hesitation in pronouncing a favorable verdict upon the work, the scholarship of which is above criticism.

A Hand-book of Dermatology for Students. By A. H. Ohmann-Dumesnil, M.D. Pp. 167. St. Louis: St. Louis Medical and Surgical Journal Publishing Company.

This pocket manual is a syllabus of the lectures delivered in one of the St. Louis colleges. The cuts are surprisingly good for a work of this kind, while the text is brief and to the point.

Original Investigations of Cattle Diseases in Nebraska, 1886–1888. By Frank S. Billings, Director State Patho-Biological Laboratory. Lincoln: State Journal Co. 1889.

The various parts of this book have previously been issued in the form of bulletins. The various diseases discussed are Texas fever, the corn-stalk disease, "hydrophobia" in cattle, "contagious diseases of the cornea," etc. It contains much interesting material, but is, unfortunately, very controversial in tone.

The Medical News Visiting-List. 1890. Philadelphia: Lea Brothers & Co. 1889.

Among the visiting-lists that are annually offered to the medical public, this is one of the most popular. It is of convenient size, and the text contains much matter that may prove valuable for speedy reference.

Foods for the Fat. A Treatise on Corpulency and a Dietary for its Cure. By Nathaniel Edward Davies, M.R.C.S. English-American edition, edited by Charles W. Greene, M.A., M.D. 12mo, pp. 138. Philadelphia: J. B. Lippincott Co. 1889.

This little book goes over ground often trodden before, advocating the physiological treatment of obesity by dietetic regulations concerning the use of the carbo-hydrates. It contains excellent dietary tables, although a great many readers will hardly believe that saccharine is better and sweeter than sugar.

Essentials of Materia Medica and Therapeutics (Saunders' Question-Compend Series). By Henry Morris, M.D., etc. Philadelphia: W. B. Saunders. 1889.

In this students' manual are set forth the principal facts concerning this branch of medical study. It well sustains the reputation of its predecessors in the same series.

Mother, Nurse, and Infant. A Manual especially adapted for the Guidance of Mothers and Monthly Nurses. By S. P. Sackett, M.D., Ithaca, N. Y. 12mo, pp. 386. New York: H. Campbell & Co. 1889.

The author has shown a commendable desire to educate the nurse and mother regarding the requirements of child-bearing, surgical accidents, and the more common diseases. In all this he has succeeded reasonably well. The mother and nurse will find much in this book which it is worth while to know, but also much which it is not necessary to know. In the latter regard the author has shown lack of judgment in trying to teach some of the more technical points in medicine, which are impossible of comprehension to ordinary people. In his efforts to give hints as to prescribing even powerful remedies, as aconite, veratrum viride, morphine, etc., he oversteps the bounds of prudence. For instance, what right has a mother or nurse to attempt anæsthesia with chloroform when only a paragraph is devoted to the teaching? Then the prescriptions given are open to serious criticism as entirely uncalled for. Again, there must have been some very careless proof-reading, otherwise we would not find the genitive, nominative, and accusative cases so ridiculously mixed; and why attempt Latin at all? We are somewhat shocked to see such spelling as post partem, suppositary, meningetis, albumanoid occurring repeatedly throughout the work.

The Electric Illumination of the Bladder and Urethra. By E. Harry Fenwick, F.R.C.S., Eng. Second edition. 8vo, pp. 271. London: J. & A. Churchill. 1889.

The second edition of this useful work comes to us profusely illustrated, very much enlarged, and almost entirely rewritten. In it are now incorporated a large number of practical illustrations of the value of electric illumination of the bladder and urethra in the diagnosis of obscure vesico-urethral diseases. The cystoscope used by the author is a modification of the Nitze-Leister instrument, and appears to be admirably adapted to its purpose in studying the interior of the bladder and urethra in all of the various diseased conditions of those organs. His remarks on the methods of examination are very practical and intelligible, and open up an entirely new field in genito-urinary surgery.

Transactions of the Association of American Physicians. Vol. IV. 8vo, pp. 378. Philadelphia. 1889.

The fourth volume of the Transactions of this Association adds another valuable one to our current literature. In it are presented interesting papers upon general paralysis, tetany, thrombosis, chylous diseases, chlorosis and allied blood diseases, gastric neurasthenia, diphtheria, and diseases of the renal and gastro-intestinal apparatus.

A Manual of Obstetrics. By A. F. A. King, A.M., M.D., Professor of Obstetrics and Diseases of Women and Children, Medical Department Columbian University, Washington, D.C. Fourth edition. 12mo, pp. 430. Philadelphia: Lea Brothers & Co. 1889.

In the present edition of this excellent and practical work two new chapters have been added on the subjects of intercurrent diseases of pregnancy and resuscitation of still-born children. Numerous new illustrations have also been introduced.

Papers Read before the Medico-Legal Society of New York from its Organization. First series. Medico-Legal Journal Association, Publishers. 8vo, pp. 552. New York. 1889.

This is a well-printed volume of the more important papers read before the Medico-Legal Society, and covers a variety of subjects bearing upon crime, insanity, life insurance, etc., studied from the stand-points of medical jurisprudence. It is embellished by portraits of distinguished members, some of whom are still living.

A Compend of Human Physiology. By Albert P. Brubaker, M.D. Philadelphia: P. Blakiston, Son & Co. 1889.

This book is now in its fifth edition, which has been revised and contains a table of "physiological constants." We have personal knowledge that it is highly prized by students. Its text and illustrations are both excellent.

A Guide to the Diseases of Children. By James Frederick Goodhart, M.D., Physician to Guy's Hospital, etc. Revised and edited by Louis Starr, M.D. Second American from third English edition, pp. 771. Philadelphia: P. Blakiston, Son & Co. 1889.

In this edition the principal changes are a rearrangement of matter, the insertion of typical temperature charts, and a special elaboration of the subject of "Feeding Infants and Children." The great feature of Dr. Goodhart's work is the close resemblance of the text to actual bedside teaching. In this line it has achieved pre-eminent success. We commended highly the first edition, and considerable subsequent experience with it has only enhanced the opinions then expressed. We know of no text-book on pediatrics which, for plain common-sense, is its superior.

Wood's Medical and Surgical Monographs, consisting of Original Treatises, and of Complete Reproductions, in English, of Books and Monographs selected from the Latest Literature of Foreign Countries, with all Illustrations, etc. Volume IV. New York: William Wood & Co. 1889.

This volume of Wood's Monographs completes the series for 1889. The first number contains an interesting essay entitled "The Influence of the Male Element upon the Female Organism," by Dr. John Brown, of Glasgow; an account of some experimental researches to determine the modifications of the internal and external temperature of the human body resulting from muscle-kneading, made by A. Symons Eccles, M.D.; and a very practical treatise on "The Diseases of the Breast," by Mr. Thomas Bryant, of London. The latter treats very thoroughly of the affections of the breast, and is illustrated with numerous wood-cuts and four chromo-lithographic plates. In the number for November we find a short monograph on "The Surgery of the Knee-joint," by Mr. C. B. Keetley, of London; "Aids to Ophthalmic Medicine and Surgery," by Mr. Jonathan Hutchinson, Jr., of London; and a translation of the most excellent treatise of Dr. C. J. Salomonsen on "Bacteriological Technology for Physicians." The following are the essays contained in the third and concluding number of this volume: "A Practical Treatise on Baldness," by Dr. George T. Jackson, of this city; "The Sphere, Rights, and Obligations of Medical Experts," by Dr. James O'Dea; "Pathology and Treatment of Ringworm," by Dr. George Thin; "Notes on Dental Surgery," by Dr. J. Smith; "The Pathology and Treatment of Scarlet Fever," by Dr. H. von Ziemssen; and "Sounding for Gall-stones, and the Extrusion of Gall-stones by Digital Manipulation," by Dr. George Harley. It will be seen, from this hasty enumeration of the contents of the fourth volume, that it is not behind those which have preceded it in variety of subjects and in the practical utility of the essays. Most of them are such as will interest the general practitioner, and it is safe to say that there is not a number in the whole year which does not contain something to interest and instruct any reader, whatever his special tastes or requirements may be. The profession of the country is indebted to the enterprising publishers of these monographs for a vast amount of first-class medical literature at a very moderate price.

Inebriety: Its Etiology, Pathology, Treatment, and Jurisprudence. By Norman Kerr, M.D., F.L.S. Second edition. London: H. K. Lewis. 1889.

Dr. Kerr's work has reached its second edition, and is familiar, no doubt, to some of our readers. In it the author preaches insistently the doctrine that inebriety is a disease allied to insanity. He devotes several chapters to a discussion of its forms, its etiology, its pathology, and its treatment. There is much of interest also upon its medico-legal aspects.

It is unfortunate, we think, that none of the English and American writers on inebriety have been pathologists, and that the subject has been approached always from its clinical side. A great deal is made out of the statement that "inebriety is a disease," and this view has been almost forced upon the profession by the prolific argumentation of its adherents.

A clearer understanding of what is meant by disease, and what by a habit, might perhaps have made the views of this school more acceptable. Every physician meets cases in which this so-called disease is cured by a single mighty effort of the will, and hence he does not feel that it is quite in the same category with epilepsy and insanity, where volition exercises but little influence.

But apart from the disease doctrine of Dr. Kerr, which may, after all, suit most readers, his book contains a great deal of interesting clinical and therapeutical matter, and embodies systematically a great deal of our modern knowledge of inebriety.

A Text-book of General Therapeutics. By W. Hale White, M.D., F.R.C.P. With Illustrations. London and New York: Macmillan & Co. 1889.

This book covers a branch not much dwelt upon in ordinary therapeutical works, but nevertheless one whose importance is continually being more and more recognized. For the author deals not with drugs, but with climate, exercise, diet, water, lavage, massage, venesection, electricity, and even hypnotism and suspension.

The subjects are clearly discussed and well presented, and we can heartily commend the work.

Les Agents Provocateurs de l'Hystérie. Par Georges Guinon. Paris: Aux Bureaux du *Progrès Médical*. A. Delahaye et Lecrosnier, Éditeurs. 1889.

The author, under the above title, discusses essentially the etiology of hysteria. He dwells especially upon its relation to injuries and shocks, and to organic diseases, and his observations here have much medico-legal importance. Many histories are given, so that the work is a contribution also to the symptomatology of the disease, reflecting the views of the Charcot school.

Essay on Medical Pneumatology: A Physiological, Clinical, and Therapeutic Investigation of the Gases. By J. N. Demarquay, Surgeon to the Municipal Hospital, Paris, etc. Translated, with Notes, Additions, and Omissions, by Samuel S. Wallian, M.D., New York. Pp. 288. Philadelphia: F. A. Davis. 1889.

The general line followed is, first, a study of the gases of the blood (oxygen, carbonic acid, and nitrogen) in their physiological condition. Then come chapters on the physiological effects, mode of preparation and administration, and therapy of oxygen, nitrogen, monoxide of nitrogen, and hydrogen. Dr. Wallian's own work in this line admirably fits him for the duties of translator and editor, and the last seventy pages of the book are a recital of his own experience. There exists great diversity of opinion among physicians as to the practical value of oxygen. The translator has a due sense of realizing that it is not a panacea, and wisely avoids claiming too much for it. The book is a reliable account of the history and present status of this class of remedial agencies.

Materia Medica, Pharmacology, and Therapeutics. By John V. Shoemaker, M.D., and John Aulde, M.D. Vol. I. 8vo, pp. 352. Philadelphia: F. A. Davis. 1889.

In the preparation of this book the authors have desired to take the position of "those who study what they see, reflect upon what has been recorded, and deduce from the knowledge thus acquired the inferences warranted by the facts." Their work shows somewhat of a reaction from the prevalent tendency to deduce the therapeutic effects of a drug from its toxicological effect upon animals. This first volume goes over the general ground of remedial agencies, modes of medicating, classification of drugs, etc., and their mode of action. The next volume (the concluding one) will contain a detailed account of each drug. The present discusses exhaustively electro-therapeutics, oxygen, hydro-therapy, massage, heat and cold, mineral waters, hypnotism, suspension, light, music, etc. The physiological effects of waltz music are "to cause the maiden's heart to beat, her eye to sparkle, her cheek to flush, and her foot to beat time."

Minor Surgery and Bandaging. By Christopher Heath, F.R.C.S. Ninth edition. 12mo, pp. 361. Philadelphia: P. Blakiston, Son & Co. 1889.

We venture to say that there are very few graduates of the last thirty years who have not, at some time or other, owned a copy of this manual. It is down to the latest date in every improvement. Any book that can last thirty years speaks for itself. It has no superior in its field.

Society Reports.

PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, February 7, 1890.

FRANCIS P. KINNICUTT, M.D., PRESIDENT, IN THE CHAIR.

Case of Epilepsy Dependent Apparently upon Dyspepsia.—DR. BEVERLEY ROBINSON presented a man, thirty-one years of age, with the following history: He had always been healthy; was in nowise intemperate; had been suffering four years from epileptic attacks and dyspepsia. When he eats something which disagrees with him, he has general convulsions that night. He had one November 5, 1889; came to me on November 6th, next morning; had an attack one month previous to November 5th, another six months previously, and still another fifteen months previously. The attacks were nocturnal, occurring when he was asleep. He loses consciousness, is at first rigid, then comes twitching all over, biting of the tongue. He is happy in life; not overworked. Very little anxiety makes his head whirl and hands shake. He drinks very little spirituous liquors.

He attributes his dyspepsia to eating pastry originally. The first attack took place four years ago, after some mental anxiety, and while eating a dinner of veal. He felt numbness in the right arm, went upstairs, and fell down unconscious.

He is now careful as to diet, drinks no tea nor coffee. Has a tendency to be constipated, belches wind frequently, head gets hot when suffering from dyspepsia. Heaviness in the head and dull headache come on two hours after an ordinary meal. No worms. Urine normal. Bromo-caffeine always relieves the headache.

November 14th commenced washing the stomach. Reaction of stomachal contents alkaline. Only a little fluid in the stomach after a test-meal the previous night. Everything perfectly digested. The meal consisted of bread, meat, and custard.

January 4, 1890, began administering dialyzed iron. Previous to washing the stomach, had used different antidyspeptic combinations with only slight good effect. Patient was feeling much better until January 18th, when he ate bananas at the evening meal. The next day he felt poorly. Washed out the stomach, which caused some relief. January 20th, 9 A.M., he ate buckwheat cakes. At 1.30 A.M., January 21st, he had an epileptic seizure which his wife heard from the adjoining room. Had taken large doses of bromo-caffeine January 19th, but it did him no good, increasing rather than decreasing the unpleasant stomach sensations.

Ordered continuance of stomach washings and the use of iron; fifteen grains of bromide of sodium at bed-time. Very careful diet, abundance of milk. The last three attacks have been at intervals of eleven and six weeks, more frequent than previously, although the condition of the stomach has been improving, especially since beginning the use of the stomach tube, more than two months ago.

Queries.—Is epilepsy caused by stomachal conditions? Shall we in this case use bromides continuously? How far may general anæmia cause attacks? The hæmoglobin in the blood in this patient is seventy-five per cent. of the normal amount.

When the patient first came under my care, he complained of dropping from the post-nasal space, for which I made a few applications of tincture of iodine. Latterly he has not complained of this dropping, and he states it has improved since he has irrigated his stomach. At present he has it in the morning, but it is less annoying than formerly. He is not conscious of obstructed nasal breathing. On examination I find quite free nasal passages, and the passage of a probe everywhere does not discover any abnormal sensitive areas, not even producing sneezing.

Dr. J. B. Emerson was requested to examine the patient's eyes, and he has written me as follows:

"DEAR DOCTOR: I have examined your patient's eyes twice, with the following results: Vision, right eye=$\frac{20}{20}$; left eye=$\frac{20}{20}$=normal. Can read No. 1 Jaeger at six inches, which is normal.

"There is no insufficiency of the superior or inferior recti muscles. There is an insufficiency of the internal recti muscles at 20 feet, of 6° to 8°; at 1 foot, of 14° to 16° by Graefe's test. The internal recti overcome a Pr. of 22° (varies). The external recti overcome a Pr. of 12° (varies). The ophthalmoscope shows the refraction of the eyes to be slightly hypermetropic, with perhaps a little astigmatism. There is a crescent of choroidal atrophy on the outer side of each nerve; this I think is physiological. Javal's ophthalmometer shows that there is about .50 of a dioptra of corneal astigmatism.

"My diagnosis of the case is astigmatism, with insufficiency of the internal recti muscles. My advice to the patient is to have his astigmatism corrected by using the proper glasses. The insufficiency will then disappear, I think. I do not think his eyes have anything to do with his epileptic attacks."

Would try Antipyrin.—DR. A. H. SMITH said it seemed to him to be one of those cases which was not very rare, in which the history began with some irritation generally preceding the epileptic attacks, the attacks gradually, however, taking place independently of that source of irritation, or of any other which it was possible to discover, and becoming more and more frequent. As far as treatment was concerned, he would feel inclined to try antipyrin, administered regularly, instead of bromides. He believed this and certain other allied drugs possessed a greater influence over the nervous system than did bromides, and probably could be used with safety any length of time.

Idiopathic Epilepsy.—DR. C. L. DANA agreed with Dr. Smith, that it was probably a case of idiopathic epilepsy, and did not attach much significance to the dyspepsia as a factor in the etiology or cure. He would most decidedly say such a case ought to be treated as if it were a serious case of epilepsy, and place the patient on those drugs which generally had been found most reliable in this disease. He did not believe epilepsy could be cured by washing out the stomach, nor by any drugs or dieting intended to correct indigestion. Yet these were not to be neglected.

THE PRESIDENT remarked that we very frequently saw attacks of indigestion followed by attacks of epilepsy, but he believed it was in cases in which idiopathic epilepsy existed. A great deal could be done in controlling the epilepsy by measures directed against the form of irritation which gave rise to the seizures. He had had one very severe case of epilepsy under observation for years, in which an attack could always be produced within a few hours by the administration of a food which caused irritation of the stomach.

Pet Theories.—DR. ROBINSON thought the case illustrated very well how readily one, with a pet theory regarding the etiology of the disease, could fall into error. The rhinologist, inquiring no further into the case than what related to his specialty, might have attributed the epilepsy to reflex irritation from the nose; the oculist, to reflex irritation from the eyes; others, to reflex irritation from the stomach.

The Value of Restricted Diet.—DR. DANA referred to the case of a boy, now under his observation four months, who had previously been treated for years for epilepsy of severe form, the minor attacks occurring every day. Finding the stomach much disordered, he put the patient on strict diet, stating exactly what he should eat, regulated the bowels, and gave no medicines whatever. It had now been four months since he had had any at-

tacks, either of *petit mal* or *haut mal*. He did not, however, regard the boy as cured, and had lately given him some neurotics in order to brace the nervous system against that sensitiveness which readily yielded to irritations calculated to bring on epileptic attacks.

Latent Epilepsy.—Dr. V. P. Gibney inquired of Dr. Dana what meaning he attached to the term "latent" epilepsy.

Dr. Dana replied that a patient who, like the boy just spoken of, had had epilepsy, the attacks ceasing on removal of an irritation in the stomach or elsewhere, might be said to have latent epilepsy, for there was likely to be a return of the attacks upon any indulgence, alcoholic, sexual, or dietary.

Dr. Gibney said he had seen two or three cases of epileptiform seizures recently, in the Children's Hospital, which had puzzled him somewhat. One was in a girl, fourteen or fifteen years of age, who had come into the hospital about two months ago from one of the orphan asylums of the city, with diffuse osteo-myelitis of the tibia. He chiselled down into the bone in two or three places, cleared out the abscesses, and the patient was doing very well, when one night she surprised the house-staff with a convulsive seizure which lasted ten or fifteen minutes, during which time she was in a semi-conscious state. She did not bite the tongue, nor manifest signs particularly characteristic of an epileptic attack. The cause of the seizure could not be traced to the condition of the wound, nor to any error in diet. Three or four weeks later, which was about a week ago, she had another similar attack. In the asylum where she had previously been they were positive she had never before had an attack.

Another case occurred in a boy eight years of age, who was sent to the hospital three or four months ago for an operation on the tarsi. After the operative wound had nearly or quite healed, and while the boy was in very good condition, he one evening had an alarming epileptiform seizure. It was thought to have been due to something which he had eaten, or to intestinal derangement of some kind. Next morning his temperature was 101° F., and he complained a little of his throat. Dr. Holt was called, and he diagnosticated simple tonsillitis with inflammation of two or three follicles, which disappeared after two or three days.

The third case was that of a boy about ten years of age, who had deformity of the knee which Dr. Gibney was trying to overcome by apparatus. There had been no suppuration for a long time. Day before yesterday he had an epileptiform seizure which lasted twenty minutes. During the convulsive seizure he did not bite the tongue nor pass urine. The house-staff were inclined to think it was due to intestinal irritation of some kind. Dr. Gibney had known the patient for years, and could say this was his first convulsion. In the case of the second patient, the parents never knew him to have an epileptic attack. In reply to an interrogatory by Dr. Smith, he said he did not know whether there was anything in the family history to account for the condition.

Operations for Epilepsy.—Dr. Bryant mentioned two cases in which operations had been performed for epilepsy. One of the patients was trephined, presumably at the place where he had sustained a blow, and which it was thought might be the cause of the attack. There had been no recurrence of the attacks since the operation, about fifteen years. It was but fair to say, however, that nothing was found where the bone had been removed to warrant the belief that depression had ever taken place, or that any pathological change had taken place to account for the epilepsy.

The other case came under his own observation three years ago. Both vertebral arteries were tied simultaneously at the point of their admission to the transverse processes of the sixth cervical vertebra. But it did not control the epilepsy. It simply diminished the number of the attacks for two or three days. The case was in a young person, without, as far as could be learned, any hereditary tendency.

Dr. Joseph D. Bryant read a paper on "Rupture of the Bladder: A Case with Mistake in Diagnosis" (see page 229).

What Caused Death?—Dr. George F. Shrady said that in listening to the very interesting paper of Dr. Bryant he had imagined himself in the reader's place while examining the case, and it seemed to him that really nothing more could have been done under the circumstances. All the symptoms were really negative. But it occurred to him to ask, Of what did the patient die? There was a history of a supplementary bladder, so to speak, formed by adhesions in the vesico-rectal pouch and among the adjacent coils of intestine. Was there a rupture of the supplementary bladder and collapse from general peritonitis, or was the case one of septic peritonitis?

Dr. Bryant remarked that the autopsy was, of course, very imperfect under the circumstances. Besides the conditions described in the account of the autopsy, there was presumably commencing general septic peritonitis, which must have arisen from the primary extravasation.

Was there Septic Peritonitis?—Dr. Herman M. Biggs said the entrance of urine into the peritoneal cavity would certainly be sufficient to cause fibrinous exudation and adhesion among the coils of intestine which went to form the pouch about the seat of rupture, but he recognized nothing in the history, nor in the notes of the autopsy, which went to show that there was septic peritonitis.

Dr. W. M. Polk inquired of Dr. Biggs how he would explain the presence of general peritonitis if there were not septic poisoning?

Dr. Biggs replied that he would call it simply fibrinous peritonitis, due to the presence of a non-septic fluid in the peritoneal cavity. If there was septic peritonitis, the poison, probably, had been introduced with the catheter, but there was nothing in the history to show that it was septic. He would suppose that if a fluid like urine were introduced into the peritoneal cavity, and allowed to remain sufficiently long, it would cause simple fibrinous exudation, but not sepsis.

Dr. Polk said he asked the question, not because he doubted the doctor's conclusion, but because in peritonitis due to injury or operative procedure, gynecologists were in the habit of calling it septic. He had not been able to convince himself, however, that all these cases of peritonitis were of septic origin. For instance, in cases similar to the one narrated by Dr. Bryant, in which only a few hours, perhaps twelve, before death the temperature suddenly rose, the pulse changed, and the patient died, apparently of collapse. At the autopsy one found just the slightest evidence of peritonitis throughout the abdomen; no fluid.

Dr. Biggs said such cases might be septic, and they might not. Usually, where the peritonitis came on in that way after an operation, and ended fatally in a short time, it was due to septic infection. The only way to determine positively whether sepsis was present, was to search for bacteria.

Dr. J. West Roosevelt thought the sole way to differentiate forms of peritonitis according to their etiology, was by the use of the microscope. Practically, he thought, surgical cases might well be regarded generally as of septic origin, and early death be attributed, as in analogous cases of infectious diseases, to a large dose of the specific poison.

Puncture Versus Exploratory Incision in Hepatic Disease.—Discussion on this subject arose in connection with a case which had been recited during the evening, and in which exploratory incision had been made in preference to puncture.

Dr. Beverley Robinson had given his reasons for preferring puncture to incision in this case, even though adhesions might not have formed, as follows: In most cases the gall-bladder could be avoided; if one passed through

the abdominal wall with a long hypodermic needle, he could penetrate deeply into the liver and do no particular harm. In fact, he did not believe there was any danger unless pus was withdrawn and some oozed out into the peritoneal cavity after withdrawing the needle. But in that case one had already acquired positive knowledge that pus was present, and could treat the case accordingly. Then, too, there was also risk of pus entering the abdominal cavity when the abdomen was opened and the hypodermic needle passed into the liver in different parts. Add to this the further fact that in opening the abdomen, atmospheric conditions came on the ground, and the comparative simplicity of exploration by puncture became manifest.

He had had a case in the medical wards of St. Luke's Hospital, three or four years ago, in which repeated punctures were made into the liver, pus being found prior to an operation, and no harm resulted, apparently, from the punctures. In his own person he would much prefer puncture by the hypodermic needle to opening of the abdomen, manipulation, and puncture of the liver by the surgeon.

Puncture Should be Made on the Convex Surface.—Dr. Andrew H. Smith thought that if the puncture were made on the convex surface of the liver, where the hepatic and diaphragmatic peritoneum came closely into contact, the amount of pus which could escape through the puncture with a fine needle would be very small, and would readily be shut off by exudation. If, on the contrary, the needle were introduced from below into the concave surface of the liver, he would expect danger.

Dr. Roosevelt inquired in what proportion of cases had harm followed puncture of the liver in the many instances in which it had been performed. It was known that opening the abdomen had done a good deal of mischief, and he did not see why an exploratory incision should be made when all objections to it were taken into account.

Danger of Puncturing the Gall-bladder, the President remarked, constituted an important objection to the use of the hypodermic needle. This accident had been followed almost immediately by fatal general peritonitis, in spite of the supposed antiseptic qualities of the bile. Further than that, he was not aware of injurious consequences following puncture of the liver.

Appendicitis Simulating Typhoid Fever.—Dr. Polk related the case of a patient who in November or October, 1888, began to suffer from a disease which his physicians pronounced a mild type of typhoid fever. At the end of four weeks the fever subsided. There had been some pain in the right iliac fossa. At the end of the fifth week there was a relapse, the patient having chills and elevation of the temperature, supposed to be due to some complication or sequel of the typhoid attack. Dr. Polk saw him about this time, and they again made careful examination, and found some consolidation at the base of the right lung which had previously been overlooked. The diagnosis of empyema was made. He was brought to the city, where he remained two weeks, too feeble to permit of an operation, and abscesses developed along the line of the long bones, indicating general infection. Dr. Thatcher made an autopsy in January, 1889, and found a small perforation of the vermiform appendix, and indications of an old abscess. There were abscesses in the liver, one in the lower portion of the right lung surrounded by consolidation, and abscesses in other parts of the body; but the chief interest in the case was the fact that its origin, apparently, was the same as in the case which had given rise to the discussion, namely, an abscess at the appendix which had been overlooked by the medical attendants. It was still a question whether the case began as a mild continued fever of typho-malarial origin, or whether it was due to the condition about the appendix which seemed to have been present a still longer period. Large white kidneys were also found at the autopsy, and it was not unlikely death would have followed any operation undertaken after the patient came under Dr. Polk's care.

Prefers an Exploratory Incision.—Regarding puncture of the liver by the hypodermic needle, Dr. Polk said the supposition was that the point of puncture became sealed by exudative material, and by contraction of a certain amount of erectile tissue which was recognized here as well as in ovarian and parovarian cysts. He frankly admitted, however, that for his own part he would rather make an exploratory incision.

It was voted to postpone further discussion on this subject until the next meeting.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, February 4, 1890.

George W. Jacoby, M.D., President, in the Chair.

Multiple Cerebral Softening with Widespread Endarteritis, and a Dissecting Aneurism of a Branch of the Left Middle Cerebral Artery.—Dr. Christian A. Herter described a case of the above. The following is an abstract of the history of the patient:

The patient, M. L. D——, was thirty-two years of age. Her family and personal history were negative. The patient indulged in the use of beer and light wines in moderation. No history of syphilis could be obtained, and syphilitic infection seemed improbable.

Up to the beginning of her fatal illness, the patient was in ordinarily good health. On the morning of March 2, 1888, she had an attack of left hemiplegia, without loss of consciousness. In the course of two or three weeks there was sufficient recovery of power to enable her to walk with the aid of a cane. A second attack of hemiplegia occurred seven months after the first. This time the paralysis was on the right side and was accompanied with motor aphasia. No loss of consciousness, properly speaking, occurred at the time of the attack. The patient became apathetic, but could be roused without difficulty. On November 15th, ten days after the second attack, she was admitted to the Presbyterian Hospital in a condition of stupor. Examination failed to discover evidences of thoracic or abdominal disease. The condition of the various forms of sensibility could not be determined, owing to the patient's mental state. The plantar reflex and knee-jerk were absent on the right side. The pupils reacted normally. The hemiplegia was difficult to make out, owing to the mental state. Urine and fæces were passed unconsciously, but there was no sphinteric weakness. Two weeks after admission, a slight rise in temperature was noted. During the remaining period of her life—a period of two weeks—the temperature ranged irregularly between 101° and 104° F. No physical signs of thoracic disease were detected. There was no cough. Four days before death, there appeared conjugate deviation of the eyes to the left. This condition continued without change until death. There were no ophthalmoscopic changes. Three days before death, the left arm became cataleptic. This localized catalepsy persisted until death. On December 14th, the patient died in coma. The autopsy showed the presence of double hypostatic pneumonia. The other viscera were normal. The meninges were normal. The left hemisphere was distinctly larger in every dimension than the right. Coronal sections showed the existence of several foci of softening. One of these, of considerable extent and recent date, occupied a large part of the left frontal lobe, and the motor path between the internal capsule and the cortex. A small cicatrix was found in the right hemisphere, occupying the lateral half of the caudate nucleus and the mesial part of the internal capsule.

The arteries at the base of the brain appeared normal, but a careful microscopical examination showed the existence of widespread endarteritis of the medium-sized and small arteries of the brain. Degenerative changes were not observed in any vessel.

A very remarkable condition was discovered in a large branch of the left middle cerebral artery. The walls of this vessel, in addition to being the seat of endarteritis, were separated by a hemorrhage of considerable size, constituting a dissecting aneurism. The presence of this clot between the elastic layer and the media, caused the complete occlusion of the vessel.

No accurate diagnosis of the nature of the cerebral lesions above described was made during the life of the patient, as nothing whatever was known of her history before admission to the hospital, until the time of her death, when the facts incorporated in the clinical history were brought to light.

The existence of localized catalepsy in this case is of interest in connection with the lesion observed in the right internal capsule and caudate nucleus. This focus, which is older than the larger lesion on the left side, is unquestionably related to the first hemiplegic seizure noted in the clinical history. Perhaps it is also related to the catalepsy. This view is supported by the localization and persistence of the cataleptic rigidity.

By far the greatest interest of this case lies in the peculiar form of arterial disease that has been described. The facts of the case and the microscopical appearances make it highly probable that the aneurism was operative in the production of the area of softening in the left hemisphere. It is believed that this is the first case of arterial occlusion from intra-arterial hemorrhage that has been described.

Dr. Fisher said that he had observed many cases of endarteritis and softening among the aged in the city almshouse. He described the case of a woman who was dull and stupid, had had two attacks of aphasia, together with hemiplegia, and who was syphilitic; syphilis and alcoholism being common to most of the almshouse inmates. In this patient there was undoubted occlusion of arteries and softening. He believed it would be impossible to distinguish between syphilitic and atheromatous disease of the vessels. He had noted as quite characteristic of specific cerebral endarteritis, extreme dulness and stupidity. Often the pupils were irregular and sluggish in their reaction to light. He would consider the hebetude in Dr. Herter's case as due to the general condition of the vessels rather than to the lesion in the frontal lobe.

Dr. Starr asked the reason of the asymmetry of the hemispheres presented in the drawings.

Dr. Herter said that œdema of the left side was the cause of the disproportion. In reply to Dr. Fisher, he stated that his case was not syphilitic, and the age was but thirty-two. Naturally, softening was common in people of advanced age.

Epilepsy.—Dr. Frank H. Ingram then read a paper entitled "A Contribution to the Study of Epilepsy." An analysis made of eleven thousand epileptic seizures, occurring in one hundred and ten patients, showed a predominance of diurnal attacks. The author said that faulty digestion, retained urine, and bad dreams were responsible for the nocturnal fits, and that vascular weaknesses and various so-called functional disturbances could be assigned as the exciting causes of most of the others. Sudden barometric and thermometric changes, particularly the former, were potent in producing epileptic explosions.

Reports of three autopsies were given, two of which showed pathological conditions in the brain which would account for the convulsions. In one case, in which the spasms invariably began in the left lower extremity, aneurismal vessels, subcortical, were found in the leg centre of the right hemisphere of the brain. In another case, excepting that there was also a loss of hearing, there were fibrinous and caseous deposits and pressure degeneration about the leg-centre in the right hemisphere, with caseous granules in the sheath of each auditory nerve. The third case showed degeneration in the posterior horns of the lateral ventricles, which, the writer said, was the only case in his experience which showed degeneration of the so-called epileptogenic zone.

Barometric Pressure and Epileptic Attacks. — The indiscriminate grouping of epileptics was condemned, and conservatism in the use of the bromides recommended. The writer professed a fixed disbelief in a definite pathology for epileptics, and cited several cases showing the marked difference in the character and the sequence of the convulsive phenomena.

Dr. Starr thought it interesting to hear of the apparent relation existing between changes of barometric pressure and the frequency of epileptic attacks. There was nothing which tended to produce epileptic seizures so soon as variations in arterial tone, a fact which might possibly serve to explain the matter of atmospheric influence.

As regarded the pathology of epilepsy, there seemed to to be no permanent lesion of the brain; and all such gross changes as had been described by Alexander, by Meynert, and others, were not the direct cause of the disease. It was inconsistent with our clinical knowledge of the disorder to seek for visible pathological changes.

Treatment of Epilepsy.—The treatment of epilepsy differed much in its results in dispensary and private practice, the former cases existing under such bad hygienic conditions. Contrasting the two classes, dispensary cases had six times as many seizures, and were in other ways worse than private patients.

There was much of value in the character of the aura. Dr. Ingram reported no aura in fifty per cent. of his cases. Undoubtedly the point of departure in epilepsy was cortical, and the character of the aura gave the seat of the discharge. If the aura were visual, as in many cases, the point of origin was in the visual area. If auditory, a rarer phenomenon, it began in the auditory area. Although the larger proportion of epileptic seizures was due to cortical disturbance, such discharge might take place from gray matter anywhere in the nervous system.

The Bromides.—It was unfortunate to condemn the bromides, for although often injurious, they gave better results than any other known drugs, when employed under proper regulations.

Dr. Herter agreed with Dr. Starr, that there was no relation between the pathological findings in epilepsy and the disease; but nutritive changes in an unstable cortex were probably the cause, apart from any gross pathological lesions.

Dr. Fisher thought that the bromides did not interfere much with bodily nutrition, as many patients grew fat on them. They seemed to become habituated to them.

Dr. Skinner described a case where the cutting off of the bromides resulted fatally. The patient, a young woman, had been for some time under bromides, when she was sent to an oculist to have her eyes examined. The latter found mixed astigmatism. The bromides were cut off. After three weeks she began to have attacks of *petit mal* very frequently; they became more and more frequent, until finally she sank into coma and died. One and one-third grain of morphia, in four doses, hypodermatically, made no impression upon the seizures. The fits invariably began upon the right side of the body, with deviation of the head to the left, and of the eyes to the right. He thought there had been a cortical hemorrhage.

Dr. Leszynsky said that the autopsy in cases of status epilepticus yielded no result. Patients died from heart or respiratory failure. He believed he had saved the lives of several such cases by venesection. He had used nitrate of amyl before he knew that it was harmful. Most drugs are of no service, with the exception of chloral, which in forty to fifty-grain doses per rectum had acted well. The indiscriminate use of bromides in epilepsy was injurious, but their careful administration was productive of satisfactory results.

Pilocarpin in Epilepsy.—Dr. Lyon had employed pilocarpin in a case with epileptic convulsions, and with excellent results, It produced first a profuse perspiration.

after which the patient emerged from his attack. In asylums it was very common to withdraw the bromides from cases, but he had never observed any harm to follow. He had used pilocarpin also successfully in a case of hystero-epilepsy.

Dr. Herter thought pilocarpin should always be employed with the greatest caution. He had seen it produce pulmonary œdema and death in two cases.

Falling Asleep while at Work.—The President related the case of a barber who, several years ago, began to fall asleep when at his work, and was consequently discharged. The somnolent attacks had continued. He would fall asleep while walking, or riding on the platform of cars, and had frequent falls into the street, into gutters, on the stove, etc., none of these things waking him up. There was no convulsion, nothing to call epileptic. Ten years ago he weighed 150 pounds; now he weighs 270 pounds. Curiously enough, he was a sufferer from insomnia, not being able to sleep continuously at night for more than half an hour. Were these epileptic attacks? Was there any connection between them and the corpulence!

Dr. Dana had reported a case of epileptic morbid somnolence in a young woman several years ago. She had had at first only somnolent attacks, later developing real epilepsy. He believed these somnolent seizures to be a form of *petit mal*. He had had a case similar to Dr. Jacoby's in conjunction with Dr. Hammond. He walked about while asleep, but did not hurt himself, and could be roused. The pupils were contracted as in normal sleep, and not dilated as in epilepsy. It might be allied to narcolepsy.

Dr. Ingram said that his routine treatment of the status epilepticus had been sixty grains of chloral per rectum every two hours, and this had been very successful in the majority of cases. He had also seen good results and no injury from the use of pilocarpin.

The Committee, consisting of Drs. Peterson, Dana, and Parsons, appointed at the January meeting to examine the "Gallup Lunacy Bill," submitted a report through its Chairman, of which the following is an abstract:

The "Gallup Lunacy Bill."—Mr. President: The Committee appointed at the last meeting of the Neurological Society to examine the proposed new lunacy law, known as the Gallup Bill, beg leave to report as follows:

"The measure has a large number of very excellent features, which, if they should become law, would prove of the highest advantage to the unfortunates whom they are intended to benefit. These are the sections relating to:

"1. The removal of the insane to asylums by attendants of the same sex.

"2. The admission and discharge of voluntary patients.

"3. The admission of emergency cases without papers of any kind for three days.

"4. The forbidding of the confinement of insane persons in jails in the same room with criminals, and any detention beyond ten days.

"5. The provision of home visits of indefinite duration at the discretion of the medical officers of the asylums.

"6. The boarding-out of suitable chronic lunatics in private families, at county expense, according to the systems in vogue in Scotland and Massachusetts.

"Aside from the invaluable particulars just described, there are several sections relating to commitment, to which there would seem to be serious objections.

"1. The method of commitment recommended is unnecessarily complicated. It may be carried out in country districts with a fair degree of patience and labor; but the difficulties of perfecting the process in the larger cities, and particularly in New York and Brooklyn, will be almost insurmountable. We are credibly informed, in fact, that some of our city judges who have seen the bill have expressed their unwillingness to have anything to do with a method involving so much of their valuable time, and will probably refuse to commit patients at all.

"2. The position of Examiner in Lunacy will be degraded to a reward for political labors, since the appointment of the two physicians in each case is left to the discretion of the county officials or judge, and not as now to the wishes of the family concerned.

"3. A majority of the patients will suffer harm from the visitation of two strange physicians and the superintendent of the poor, and from the visitation of an officer of the court with a notification of the legal proceedings about to be instituted.

"In contradistinction to these facts we have abundant testimony to the effect that, simple in comparison as is the existing law of commitment, no person has ever been, through intentional wrong-doing, placed in an asylum as insane in this State, the present method affording ample protection.

"But it is possible to make certain improvements in the law now in force, not only in the manner of commitment, but also in the means of regaining subsequent liberty; and the suggestions your committee would submit are as follows:

"1. There should be no material change in the present mode of commitment by two medical certificates, sworn to, and approved by a judge of a court of record, as provided in the Laws of 1874.

"2. Emergency cases should be received for three days without papers of any kind, as specified in the proposed new law.

"3. The medical certificates should be more carefully and thoroughly made out, not only in justice to the patient, but also for the benefit of the asylum physicians, who now rarely receive many facts bearing upon the medical history of their patients, or upon their mental conditions. To this end the form prescribed in the Gallup Bill should be adopted. A few additional questions should be incorporated in the medical certificate, for the purpose of determining whether the physicians have informed the patient of their intention of placing him in a hospital for the insane for treatment, in order to guard against the serious harm so often done to patients by removing them to an institution through deception. The State Commission in Lunacy seems to be invested with the power to prescribe the form in which the medical certificate should be made out, and a law regulating this would not appear to be necessary.

"4. There should be a section in the law permitting any higher justice, upon application from any patient in an asylum, to appoint at his discretion a commission of two or three physicians to quietly examine said patient as to his mental condition, and upon receiving their report favorable thereto, to discharge him from the custody of the asylum. By the Laws of 1889, chapter 283, section 22, the State Commission in Lunacy is empowered to make such regulations as to the correspondence of patients as would insure the proper carrying out of this law.

"5. A clause should be introduced into the bill providing that nothing in the lunacy laws of the State shall be construed to interfere with the reception and treatment of acute cases of insanity in chartered general hospitals, in the same manner and under the same conditions as patients suffering from other diseases are there received and treated, provided such hospitals have suitable accommodations approved by the State Commission in Lunacy.

Signed, Frederick Peterson, *Chairman.*
C. L. Dana, M.D.,
Ralph L. Parsons, M.D.
G. W. Jacoby, M.D., *Ex-officio.*

Dr. Starr expressed himself as thoroughly in sympathy with the criticisms and recommendations of the report. He moved that the report be adopted and printed, and that copies be forwarded to the Governor of the State, the State Commissioners in Lunacy, and to such others as were interested in the insanity laws.

After some further favorable discussion by Drs. Fisher, Leszynsky, and Ingram, the report was adopted as read, and the recommendations of Dr. Starr ordered.

THE NEW YORK COUNTY MEDICAL ASSOCIATION.[1]

Stated Meeting, held at the New York Academy of Medicine, February 17, 1890.

GEORGE T. HARRISON, M.D., VICE-PRESIDENT, IN THE CHAIR.

DR. GEORGE T. HARRISON, the Vice-President, reviewed the work of the Association during the past year, and referred to the late Dr. Charles S. Wood, who, as the President, had contributed so much by his enthusiastic efforts toward their success. He paid a graceful tribute to Dr. Wood's many virtues.

Radical Cure of Hernia.—DR. EDWARD VON DÖNHOFF read a paper on the "Radical Cure of Hernia," immediately after the exhibition of several cases by Dr. T. H. Manley. Dr. W. B. DeGarmo took exception to some of Dr. von Dönhoff's strictures upon the inutility of the truss, and maintained that it occupied an important place in the treatment of the difficulty. He rather scouted the idea that it produced atrophic changes—at least to any important degree—in the underlying tissues. He pointed to the fact that there were thousands who depended for their safety upon the contrivance for a long series of years, and would hearken to no other suggestion for their relief. The many failures in the radical operations, he thought, would bear him out in his statements, which by some might be regarded as too pronounced.

DR. CHARLES MCBURNEY explained at length the *rationale* of the procedure which his friends had associated with his name. He did not claim infallible results, although, after a reasonable length of time they should be regarded as very encouraging. He thought that most of the failures were due to the fact that operators satisfied themselves with considerations of the external ring, and did not seek for producing causes beyond that exit of the protrusion. The approximation of the columns did not cover the entire question—a dense cicatrix, which the years could not entirely absorb, was an object well worth the aim. He then explained at length the tendency of the peritoneal pouch toward protrusion in almost every subject, and held to the view that special individual safeguards were very rare. A number of cases showing the results of the operation were presented.

DR. T. H. MANLEY confined his remarks to those cases where strangulations left no other resource than an operation for immediate relief, and argued that much time was not left for the consideration of very nice points. Still, he was much pleased with Dr. McBurney's skill and success. So far as his own experience taught, he was not inclined to abandon Dr. McBurney's methods, and was of the opinion that his logic was sound.

DR. A. PALMER DUDLEY thought that some of the failures were due to the late operations—that the time for surgical interference was before what was a mere slit became a circle. He suggested that there was yet a future in store for this radical treatment along the line of antiseptic laparotomy.

Continuous Irrigation of Deep Cavities.—DR. N. G. BOZEMAN exhibited an apparatus, the joint device of himself and father, for the continuous irrigation of deep cavities. The contrivance, which was simple, ingenious, and capable of improvised application, was on the principle of an intermittent siphon. It excited no little interest among those present, and was regarded as especially useful in gynecological practice.

Twelve members were admitted, a memoir of Dr. David C. Cocks was read, and resolutions eulogistic of the late Drs. Lewis Hall Sayre and C. S. Wood were passed. After which the meeting adjourned.

Nicotine for Hiccough.—Dr. Higginbotham states that he has cured several cases of very obstinate singultus by means of pills containing $\frac{1}{10}$ grain of nicotine.

Correspondence.

OUR PARIS LETTER.

(From our Special Correspondent.)

IS "LA GRIPPE" AN ACUTE INFECTIOUS DISEASE?—THE EFFECTS OF SULPHATE OF COPPER ON THE HANDS WHEN USED AS AN INJECTION—THE TREATMENT OF TYPHOID FEVER—LARGE FIBROMA OF BROAD LIGAMENTS—OVARIOTOMY STATISTICS—THE PATHOGENY OF GLAUCOMA.

PARIS, February 7, 1890.

THAT grippe or influenza is an infectious and a contagious malady is gaining ground in the profession. To exemplify this idea Dr. Proust read an extract of a report, at the Academy of Medicine, by Dr. d'Hoste, surgeon of a mail steamer called Saint Germain. The Saint Germain left Saint Nazaire on December 2, 1889. It put in, on the 3d and the 6th, at Pauillac, and on the 5th at Santander. At this last port a passenger of the first class embarked, coming from Madrid, where the influenza reigned. Till then the health of those on board was good; but, on the 6th, the passenger from Santander was taken with grippe; four days later the doctor of the ship fell ill, then a servant. From December 12th to January 7th, 154 out of 436 passengers, and 47 men of the crew became, in their turn, affected with the malady. The epidemic, however, was slight, and there were no deaths. Hence the conclusion that grippe is manifestly a contagious and transmissible malady, and that not only in its grave complications, as established by Professor Bouchard, but also in its simple and benign form.

Dr. Tarnier presented, at the Academy of Medicine, a young woman, an *infirmière* of the Maternity, whose duty was to administer vaginal injections of solutions of sulphate of copper to women recently confined. This woman's hands became red and inflamed, and she requested to discontinue her work. M. Tarnier observed that this was one of the drawbacks in employing the sulphate of copper as an antiseptic in such cases, as several instances of the kind just referred to have occurred. He therefore preferably employs a solution of the bichloride of mercury. Dr. Fournier remarked that this woman had a pseudo or artificial eczema of the hands, caused by the sulphate of copper, and that she is in consequence very much exposed to contract syphilis in handling syphilitic infants, which are so common in the class of patients that are treated at the Maternity. He would therefore suggest the cessation of the employment, as antiseptics, of drugs which would cause inconveniences of this kind. Dr. Féréol observed that this woman was interesting in another point of view. For the long time that she had employed the sulphate of copper, she must have absorbed a great deal, since her hands were chapped, but, nevertheless, she did not present any phenomenon of intoxication. This case would contribute to prove that copper was not toxic. Dr. Fournier remarked that this woman was not anæsthetic, but that she was analgetic. She felt the prick of a pin, but felt no pain whatever, even when this pin completely traversed the skin. It is possible that this analgesia was a phenomenon due to intoxication by the sulphate of copper.

In a note to the Medical Society of Hospitals Dr. Sorel gives the report of 105 cases of typhoid fever that he had treated. Of these 105 cases there were 100 cures and 5 deaths. The treatment consisted in the administration of the sulphate of quinine associated with the salicylate of soda. Some of the patients had baths, but more hot than cold. Dr. Sorel does not think that, for the present, the superiority of cold baths are sufficiently established to constitute a method of treatment compulsory in the army, as it is among the Germans.

At a recent meeting of the Société de Chirurgie Dr. Terrillon communicated the case of a women, aged thirty seven, and mother of seven children. From this patient he

removed a large fibroma, which was included in the broad ligaments. At the commencement of October, 1888, her abdomen measured one metre sixty centimetres in circumference. The tumor which it contained gave rise to grave phenomena, such as intestinal obstruction, dysuria, and even temporary anuria. Laparotomy was practised on October 10th. The incision, which was very long, extending beyond the umbilicus, immediately exposed to view a large tumor, very vascular, divided into several lobules, and occupying a large portion of the pelvis, and included in the two broad ligaments, forming several adhesions with the ureters, the bladder, and the abdominal walls. It was found to be a fibroma weighing nineteen kilogrammes, and developed on the posterior and lateral surfaces of the uterus. The cure was effected without incident. The patient left the hospital on the twenty-eighth day. Since that time she has always been in good health.

At a subsequent meeting of the Société de Chirurgie Dr. Terrillon gave an account of his sixth series of thirty-five ovariotomy operations. He enumerated the different cases which appeared to him worthy of remark. Of these thirty-five operations performed from February 12, 1889, to October 20th of the same year, there were only two deaths, one from peritonitis, on the fifth day, without any rising of the temperature, the other from septicæmia, on the thirty-second day. In this latter case there were several complex cysts which were very adherent.

Dr. Chauvel read a report on three cases observed by Dr. Barthélemy, of Tunis, on abscess of the liver treated by direct incision. Dr. Barthélemy incised the soft parts, layer by layer, and opened the abscess, without suturing the hepatic tissue to the peritoneum. Complete cure was the result.

Dr. Malassez submitted a paper, at a recent meeting of the Société de Biologie, on the pathogeny of glaucoma, in the name of Dr. Nicati, of Marseilles. This author had established the fact that there existed, in cases of glaucoma, capillary varices due to a spasmodic state of the iris and of the choroid, whence the production of an intra-ocular œdema and the distention of the globe of the eye. But for this œdema to become permanent it is necessary that the normal tissues by which the aqueous humor escapes should be obstructed. This obstruction is almost fatal, owing to the iro-chorodian reflex spasm. He therefore deduces a double etiological factor: 1. Capillary varices. 2. An obstruction of the canals of the aqueous humor.

THE NEW OPERATION FOR EPILEPSY.

To the Editor of the Medical Record.

Sir: Under the heading a "New Operation for Epilepsy" I notice a slight error which I think is worth while correcting.

Dr. Alexander, to whom your paragraph refers, lives in Liverpool, and is the same surgeon who is the author of the operation that goes by his name for shortening the round ligament. The operation of removal of the cervical ganglia was substituted, some years ago, by him for that of ligation of the vertebrals, but with the same object in view—of curing epilepsy through the control of the cerebral circulation. In the later operation this he attempts to accomplish by depriving the blood-supply of its vasa-motor influence—to place the brain thus far beyond the control of those causes that lead up to an epileptic seizure. He commenced this new departure in the surgery of epilepsy by the difficult feat of removing both superior and inferior cervical ganglia; but latterly, when I last saw his work (1887), he confined himself to the removal of the superior ganglia. The results of the latter, as shown in the recent cases in his wards, seemed to me to justify this ingenious procedure. Another operation that I saw him do, which also had at any rate the charm of novelty about it, but the good and bad results of which I have not heard since, was in cases of otherwise irremediable incontinence in women, due to paralysis of the vesical sphincter, to dissect up the urethra and button-hole the recto-vaginal septum, so that with the urethra secured in this position it could drain the bladder into the ampula of the rectum, to be discharged at intervals, instead of the continuous dribbling attending the former condition. Yours faithfully,

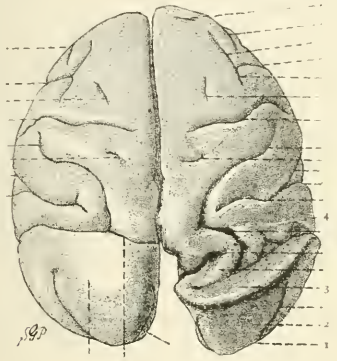
James Kerr, M.D., M.Ch.

Washington, D. C.

DOES THE POMA ("OCCIPITAL OPERCULUM") OCCUR IN THE HUMAN BRAIN?

To the Editor of the Medical Record.

Sir: Permit me to ask the anatomists among your readers whether they have observed specimens or figures of the human brain in which a portion of the dorsal surface of the occipital lobe overlaps the region just cephalad of



Dorso-caudal Aspect of the Brain of a Monkey (Macacus), the Right Poma lifted. 1, Caudal end of right occipital lobe; 2, surface caudal of poma; 3, poma; 4 (light line), line of detachment of the pomatic margin; 5, poma, 6, pomatic fissure.

it, the line of overlapping being *approximately transverse*, as represented in the last volume of the "Reference Handbook," p. 162, Fig. 4788. Analogous overlappings, constituting supergyres, may occur at almost any point upon the cerebrum, but I have not as yet found what seems to me *identical* with the poma of apes and monkeys.

Burt G. Wilder.

Ithaca, N. Y., January 11, 1890.

CONCERNING THE TREATMENT OF NEUROTIC TUMORS OF THE BREAST.

To the Editor of the Medical Record.

Sir: How great are the resources of modern therapeutics! How gigantic the strides toward the desired goal—scientific exactitude in medicine! Ovariotomists *vs.* "Apostolists," urethrotomists *vs.* electrolosists, wage warfare in which non-combatants are the killed and wounded.

When the French savant introduced the testicular secretion as a rejuvenator we supposed the ultimatum in the line of sexual vagaries attained. Not so. Readers of the Medical Record for February 15th will be rejoiced to find a new vista opened up, viz., female orgasm. The suggestive "respiration" and "facial and bodily movements," associated with an erectile uterus furnish a picture not difficult of comprehension.

The method appears to be applicable to young, unmarried females, and may perhaps be extended with beneficial results to erotic widows. It holds a similar relation to the sexual appetite as does the artificial feeding of infants to their digestive demands, and seems to be an imperfect substitute for the natural means—in the one case mother's milk, in the other, marriage.

Is this a legitimate therapeutic expedient? I should answer emphatically in the negative. If countenanced at

the outset, its applicability will become extended, just as has been the experience with every new therapeutic resource.

If orgasm occurs during necessary gynecological manipulations, it should be regarded as unfortunate. As to inducing it as a legitimate plan of treatment—never! The knife is a thousand times to be preferred.

F. Percy Jenks, M.D.

543 Tenth Street, Brooklyn, N. Y.

THE EXAMINATION REQUIRED FOR ACTING ASSISTANT SURGEONS, UNITED STATES ARMY.

To the Editor of the Medical Record.

Sir: In reply to Dr. S. S. Turner's item in the Medical Record of the 15th inst., kindly permit me to make the following explanation:

Some time in October I sent you some MS. concerning the Acting Assistant Surgeon, United States Army. In the Medical Record of November 2, 1889, you published an editorial, "The Hard Lot of an Acting Assistant Surgeon," for which we are all of us, I believe, deeply indebted for your courtesy and kindness. Just before referring to the requirements for admission, you stated, "We are indebted to Dr. W. Thornton Parker, of Newport, for *much* information on this subject." The inference with many seems to have been that Dr. Parker, either ignorantly or wilfully, supplied the information concerning examinations. No one seems to have known that another medical gentleman supplied that portion of your editorial.

When I read about the examinations I supposed it was true, as did many others, and I read it with great satisfaction. The officers on duty at the Surgeon-General's Office, and other regular army officers, seemed to think that it was published with intention to deceive. Some years ago Surgeon-General Murray prepared a circular and had it printed for distribution to those who sought for the position of Acting Assistant Surgeon—and that circular is almost identical with that portion of your editorial relating to Acting Assistant Surgeons. Hence when I saw the requirements for examination I very naturally supposed that someone familiar with the requirements of the service had given you the information, and so accepted it as a fact, and copied your entire editorial into our circular just about ready for publication. The knowledge of the existence of this circular only came to the present officers of the Surgeon-General's Office within the past few days, when by good chance a clerk found the circular whose very existence even was denied by those at present in authority.

I make the statement to show to Acting Assistant Surgeons and the medical profession in general that, in seeking for justice, we wish the aid of the strictest truth only, and need not and will not attempt stratagem of any kind in our unequal and almost hopeless battle. It is remarkable, however, that such a wide difference should exist between the position of an Acting Assistant Surgeon, who has less right and worse treatment than any military medical officer in the world, and the regular United States Army medical officer, who has more privileges and better pay than any other in any army. And yet the opposition for the relief of the Acting Assistant Surgeon and a tardy recognition of the most ordinary justice, comes from the comfortable and well-paid regular officers more than from any other source. Every senator and representative, and every general officer and other regular officers of high rank most cordially approved of the measure of justice hoped for. Surely the professional records of those who have been Acting Assistant Surgeons—containing the names of some of the most illustrious surgeons and physicians in the history of American Medical Life—will compare favorably with the records of Army Medical Surgeons, who have never served in the menial capacity of a "contract doctor." The position taken by our Association is generally admitted to be most reasonable and honorable, and the Army Medical Department can ill afford to offer any serious barrier to an effort aiming at the attainment of the most ordinary justice. The honor and welfare of the Army will be bettered, not injured, by giving the rights of American citizens in general to the corps of Acting Assistant Surgeons of the United States Army, than whom no worthier men are to be found in the United States Army to-day.

Thanking you sincerely for your friendly interest and kindness to our association in its discouraging but honorable work, I am, dear doctor,

Very truly yours,

W. Thornton Parker, M.D.,

Recorder Asso. Act. Asst. Surgeons, U. S. Army.

9 Kay Street, Newport, R. I., February 18, 1890.

Army News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from February 16 to February 22, 1890.

Smith, Andrew K., Colonel and Surgeon. Retired, February 9, 1890. Act of June 30, 1882.

Raymond, Henry I., Lieutenant and Assistant Surgeon. To be assistant surgeon with the rank of Captain, after five years service, in accordance with the act of June 23, 1874.

Smith, J. R., Lieutenant-Colonel and Surgeon. Leave of absence granted for twenty days, to take effect about February 10th. S. O. No. 15, par. 1, Headquarters Department of Arizona, February 8, 1890.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending February 21, 1890.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	13	6
Scarlet fever	81	12
Cerebro-spinal meningitis	4	3
Measles	84	4
Diphtheria	87	20
Small-pox	0	0
Varicella	4	0
Cholera	0	0

The Fate of Cadaveric Microbes.—It is a comfort to learn, on the authority of M. Esmarch, that most pathogenic microbes succumb sooner or later after their victims have died. The experiments were carried out with nine different micro-organisms, and the bodies of the animals on which they had wreaked their wicked will were either buried or kept under water, or exposed to the air. The bacillus of septicæmia survived ninety days, while that of anthrax disappeared within a week. The bacillus of fowl cholera was seldom found after three weeks, but the tubercular microbe did not lose its virulence until 204 and 252 days had elapsed. All trace of the other organisms was lost in from three days to a week, including those of typhoid fever, Asiatic cholera, and tetanus. As a general rule, the more active the decomposition, the sooner did they perish, and this is another argument in favor of "earth-to-earth" burial pending the universal adoption of cremation.—*Medical Press.*

THE TREATMENT OF PES EQUINO-VARUS BY CONTINUOUS LEVERAGE.[1]

BY HENRY LING TAYLOR, M.D.,

NEW YORK.

IN congenital equino-varus we probably have the result of arrested development of the foot, whether due, as Dr. H. W. Berg [2] believes, to failure of the thigh to rotate in, or to other causes. In this well-known deformity the heel is drawn upward and inward, and the foot is bent inward upon itself, and rotated toward the internal malleolus. These elements are present in varying degree in the different cases. Anatomical and clinical observation have shown that all the tissues, and not the muscles alone, are shortened and compressed on the concave side, lengthened and expanded on the convex side. The bony and ligamentous structures especially are shortened, narrowed, wedged, or displaced as compared to the normal foot, because growth has taken place in an abnormal position. In some specimens which have been examined it is noted that deformity persisted after all the tendons had been cut.[3]

It is thus apparent that the problem presented is to remould the foot, by artificially supplying the forces which are deficient. When contracted and compressed regions are relieved of pressure by the stretching process, their growth will be stimulated toward the natural relations of the parts.

Looking at such a deformed foot from behind, we see that the foot and leg taken together present an irregular curve with the convexity outward. If we are to attempt to reduce this curve it is mechanically advantageous to place our splint, which may be straight from below the knee to the toes, on the inner side of the leg and foot and draw them to it by strapping. This is better than putting the splint on the outer side, because in the former case we have good contact at each end to steady our splint while we are drawing the ankle in, while in the other by any method of strapping the distance between the points of firm contact is much shorter, and the apparatus consequently less fixed.

Dr. C. Fayette Taylor, when he first began to treat club-foot in 1858 or 1859, saw the mechanical advantage of placing the splint on the inner side of the foot and leg, and has used that method ever since. His early apparatus consisted of a leg-piece and foot-piece pivoted at the ankle, and so arranged that the foot piece could be set at any angle; a sole-plate was soon added. In the beginning, if there was much equinus, the foot-piece was set with the toe-end dropping so as to make an almost straight splint with the leg-piece; the splint was gradually bent at the shank to rotate the foot out; the tendo Achillis was stretched, and flexion of the ankle was progressively carried on by flexing the foot-piece of the splint and retaining it by a screw. After the foot was inverted and flexed its position was kept by wearing the appliance inside the shoe as a retaining apparatus. The brace was not attached to the shoe, for any attempt to utilize the shoe to hold the foot is disappointing, as it has no precise grasp, and the foot slips and turns inside. In 1867 Dr. Taylor visited many European clinics, among them Mr. Smith's, at the Hospital for Sick Children, Great Ormond Street, London. He found him treating club-foot by bandaging a straight piece of zinc to the inside of the foot and leg, *having first brought the foot into complete extenston*, so that it formed a straight line with the leg. As the foot yielded outward he bent the zinc with his hands to force it still further over, and kept this up until he got an equino-valgus, the lateral deformity being over-corrected, he then cut the tendo Achillis and flexed the foot.[1] Mr. Smith was not an orthopædist, but my father speaks with admiration of the precision of his mechanical sense and the excellence of his work, and acknowledges his indebtedness to him for the idea of first overcoming the varus before attacking the equinus, which he has adopted and practised ever since. Mr. Smith insisted on the advantage of preserving the tendo Achillis as a counterforce to assist in stretching the plantar ligaments and the structures on the inner side of the foot. The tendon steadies the heel while the forward part of the foot is pushed over, and the plantar ligaments are stretched from the inner side fibre by fibre.

Up to this time Dr. Taylor had employed tenotomy

Fig. 1.

Fig. 2.

freely as a step in mechanical treatment, but after adopting the method of first reducing the varus separately, he found that the resistance of the heel cord was so much lessened by the process that it yielded to the mechanical means employed much more readily than under the old plan of reducing both deformities at once, and for the same reason as in the case of the plantar fascia and ligaments. In equino-varus the tendo Achillis is inserted toward the inner side of tuberosity of the os calcis, and the inner border of the tendon is shorter than the outer; by forcing the foot out and the os calcis over, it is stretched fibre by fibre, as when we tear a bandage from the tense edge, and when the valgus position is established, the resistance is diminished. The process is analogous to that employed in the treatment of combined adduction and flexion in hip disease. The adduction is first overcome separately and then flexion is found to be lessened.

The splint, always acting from the inner side and never attached to the shoe, continued to be used and modified to meet the requirements of particular cases, and has been substantially as I show it for fifteen years. It consists, in its commonest form (Figs. 1, 2, and 4), in a steel shank

[1] Read by title at the meeting of the American Orthopædic Association, Boston, September, 1889, and in full at the Orthopædic Section of the New York Academy of Medicine, November 15, 1889.

[3] Dr. C. L. Scudder: Boston Medical and Surgical Journal, October 27, 1887, Cases II. and III.

[1] Dr. W. J. Little, in his work on club-foot, published in 1839, had pointed out the advantage of first reducing the varus, as Dr. Shaffer mentioned in the discussion. Dr. Little seems also to have used a form of leverage from the inner side in certain cases.

with guarded leg- and ankle-bands pivoted to a foot-piece of thin steel. The foot-piece has a sole-plate, and a side-plate fitted to the inside of the foot; there is a screw stop at the ankle-joint to flex the ankle, and there are straps across the instep which are guarded by a small steel bar. The shank is not usually pivoted directly to the foot-plate but to a steel H-piece which makes an offset from the ankle. The shank of this instrument is easily bent by the hand or by wrenches according to the requirements of the case.

About 1874 he began to apply a three-tailed adhesive plaster to the leg (Fig. 3), a piece of webbing attached to

Fig. 3.

Fig. 4.

the plaster was buckled to the heel of the apparatus (Fig. 4). This kept the heel from leaving the sole-plate when force was applied, and greatly increased precision. As the mechanical means became perfected, tenotomy was found less and less useful, even in cases of long standing, or in those that had relapsed after tenotomy, from imperfect mechanical treatment. It was usually found advantageous to preserve the heel tendon as an aid in unfolding the contracted tissues on the bottom and inner side of the foot, and it and the other contracted muscles readily yielded to stretching when force was properly applied, and in the proper order. There is no objection to tenotomy when it is done with a clear idea of its purpose and limitations, but it cannot be made to usurp the place of systematic mechanical treatment. Much disappointment has been caused by failure to realize that it is only an incident in the treatment of club-foot. After successful tenotomy there is still ligamentous and bony resistance to replacement which, even if for the moment overcome by force, will in time drag the foot back into a deformed position unless mechanical means are used to prevent it, and to hold the foot in position until the hard and soft tissues are remolded and in equilibrium on the two sides. In other words, whether tenotomy is used or not, mechanical treatment is indispensable. A prominent German surgeon, himself a believer in preliminary tenotomy, said to me a couple of years ago: "We in Germany have known for twenty years that tenotomy does not cure club foot." It is the means employed after the operation that mold the foot into position and retain it, and whether or not a permanent cure is effected will depend on the efficiency of the after-treatment, rather than upon the thoroughness of the tenotomy.

After applying the three-tailed plaster to the inner side of the leg in the manner shown, the foot-piece of the apparatus, the shank having been properly shaped, is securely strapped to the foot, and the plaster webbing buckled to the heel of the splint (Fig. 1); using the shank of the instrument now as a lever, the foot is thrown out and the leg-plate of the apparatus is strapped in place (Fig. 2). All straps are so placed and guarded, that there is no circular constriction of the limb, even after continuous use. The apparatus is, of course, properly padded, and is removed at least twice a day at first, to bathe the foot and make necessary modifications. The shank of the splint is gradually bent, forcing the foot over toward the valgus position. As the forward part of the foot swings outward, the original curve of the leg and foot becomes divided into two curves by the displaced heel; the upper formed by the heel with the tibia, the lower by the heel with the metatarsus. These are in turn directly attacked by our apparatus, thus pushing the foot out and over in the same manner as in the original curve, the inner side of the os calcis being added to the ball of the great toe and inner aspect of the upper end of the tibia as a fixed point of mechanical action, the convexity of the upper curve being drawn to the splint by a strap just above the ankle, that of the lower one by a strap over the cuboid and mediotarsal region.

With this leverage and padding over the inside of the heel, if necessary to increase its force, the os calcis and heel swing over into place. The position of the os calcis is the key to the situation, and it is not able to resist this direct attack. In fact, it is necessary to be somewhat cautious not to force it too far over, and leave the patient with a permanent valgus.

When the os calcis has been brought into proper position, and the deformity has been changed to an equino-valgus, the ankle is flexed by turning the set screw at the ankle-joint, the heel being prevented from rising by the plaster. During the few weeks that all this is going on it is important that the patient should not put his weight on his foot, as this throws much unnecessary strain on the plaster. When he can place the sole flat on the floor, walking in the splint will assist rather than hinder.

The apparatus must be worn day and night throughout the treatment, so that the foot may never return to the deformed position, and the contracted tissues may always be on the stretch. This moderate continuous stretching is irresistible, and is easily borne by the patient. During the prolonged after-treatment the patient is seen only occasionally, and goes about quite independently in his brace, which is completely concealed by his shoe and stocking. When the tissues of the foot are remolded and stable in their corrected position, all treatment may be discontinued, though it is sometimes better to have the splint worn at night for a time.

The above comprise the essential principles in ordinary cases, but details vary, so that each case from beginning to end is a separate study, and our means must be modified and adapted to suit each individual. We use many forms of foot-brace to suit the peculiarities of the case in hand, but always for varus retain the principle of stretching or moulding by continuous leverage from the inner side of the leg and foot.

Sometimes it is an advantage to run the brace up above the knee in order to get a better purchase on the foot. Once in a while there will be a residual inversion of the thigh after the foot deformity has been corrected. This requires a long apparatus with free knee-joint and hip-band to evert the thigh. Each mechanical indication must be carefully met as the case progresses.

The acquired varus of infantile paralysis is treated on the same principle, due regard being had in the construction of our apparatus to the condition of the opposing muscles, and of the rest of the limb. Tenotomy is seldom required. In the deformity due to spastic and cerebral palsies tenotomy is more often useful along with mechanical treatment.

The following outlines will give an idea of the results that can be attained by the employment of continuous leverage alone, even after failure with the ordinary methods.

Case I.—A girl, aged five and a half, came to me from Montreal in March, 1883. She was born with an equino-varus of the right foot, and the heel-cord and one other tendon had been cut by a surgeon at six months, and the tenotomy of the heel-cord had been repeated at ten months. The foot had been put up in plaster and she had had manipulation. At two and a half years she could place the sole on the floor and had begun to walk; from that time till seen she had worn a club-foot shoe. For a year and a half the foot had been rolling over and

growing worse; the father stated that it was then (1883) worse than it had ever been.

Examination showed that she walked on a large corn over the cuboid bone turning the foot in (Fig. 5). There was considerable rigidity and the foot could not be brought into position by manipulation.

Continuous leverage was applied and the patient was able to walk on the sole in two weeks, wearing the apparatus.

The foot gained three-fourths of an inch in length and the patient walked about with the shoe over the brace, stepping squarely on the sole of the foot in a month. She continued under treatment two years, and was shown cured (Fig. 6) at the New York Orthopædic Society, April 30, 1885. Since then she has been walking about freely without support, but has worn the brace at night to

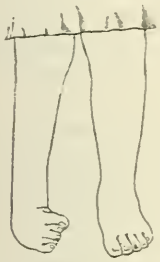

Fig. 5.—March, 1883.

Fig. 6.—November, 1884.

prevent relapse. She presents the unusual feature of three-fourths of an inch shortening from retardation of growth in the previously affected leg.

Case II.—Girl, aged five, Montreal. Brought September 21, 1885. Congenital talipes equino-varus, severe, of left foot. Heel-cord cut at three months; guttapercha splint till ten months; tenotomy of tendo Achillis repeated then and foot put up in plaster. Scarpa's shoe nine months thereafter. Patient learned to walk at nineteen months in ordinary shoe, with foot in deformed position. From two years to four and a half, brace with hip-band. Father states that she has not improved at all since ten months of age.

Examination showed patient walked on corn over cu-

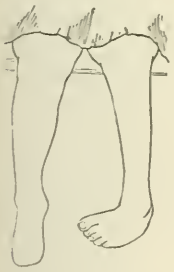

Fig. 7.—September, 1885.

Fig. 8.—October, 1886.

boid bone, the foot pointing in (Fig. 7). The distal phalanges on right foot are missing and the remaining ones webbed.

Foot came around readily under continuous leverage; patient was walking readily flat upon sole in a few months and was discharged from treatment with deformity cured (Fig. 8) in two and a half years. She walks flat on foot, turns toe out, and ankle can be flexed beyond right angle.

Case III.—Boy, aged four. Connecticut. Came in February, 1877. Severe case of double congenital equino-varus. Seven tenotomies at four operations, between third and sixth month; case reported cured, with photographs (Figs. 9 and 10). An earnest attempt was made to hold the feet by mechanical means, but in spite of many kinds of appliances and repeated tenotomies the feet relapsed. There were altogether eleven etherizations and seventeen

Fig. 9.—At two months.

Fig. 10.—At fourteen months.

tenotomies before the case was brought to Dr. C. Fayette Taylor, at the age of four (Fig. 11). He then presented a severe and typical varus with great rigidity; the feet could not be straightened by manual force. Treatment by continuous leverage was used and the deformity was corrected. Fig. 12 shows their condition in June, 1878. He wore retention apparatus several years, walking about freely, flat on his soles, and the deformity was completely overcome.

He was shown, cured, at the New York Orthopædic Society, April 30, 1885, walking perfectly flat on the soles of his feet and turning toes out. There was limited motion at the ankle. He had not worn braces for three years.

Since then, as flexion seemed somewhat diminished, I advised him to wear braces at night to keep the toes from dropping. He has done so, and his feet were, when last seen, some two years ago, nearly perfect in shape and function, except for the limited ankle motion.

I advocate the method of progressive remoulding of the foot by continuous leverage to correct the faulty moulding of nature on account of its certainty, the directness and precision with which it meets all indications, its freedom

Fig. 11.—At four years.

Fig. 12.—At five years.

from discomfort to and restriction of the patient, the perfection and permanency of its ultimate results.

The treatment of pes equino-varus is not a question of braces or of tenotomy, but of exact apprehension of the indications presented by each case throughout its progress, based upon a critical analysis of the elements involved. As Delore suggestively remarks: "You must convince yourself it is the surgeon, and not the apparatus, that effects the correction."[1]

I emphasize as important practical points:

1. The preservation of the heel-cord as an aid in unfolding the foot.

2. Exact prehension of the foot by means of an apparatus not attached to the shoe, and by plaster applied to the leg.

[1] Du Torticolis, etc., Gaz. Hebdom., March, 1878, p. 168.

3. The application of leverage to the inner side of the foot and leg.

4. The reduction, first of the varus deformity, afterterward of the equinus.

5. Thorough after-treatment.

201 West Fifty-fourth Street.

THE ANIMAL SUTURE; ITS PLACE IN SURGERY.[1]

By HENRY O. MARCY, A.M., M.D., LL.D.,

BOSTON, MASS.

Investigations upon the origin of means adapted to a given end clearly teach that active minds have already subjected the chief factors to careful analytical study, although certain phases of the problem are ever presenting themselves under new aspects. Dominated by such thought, Solomon taught that "there was no new thing under the sun," and it is quite probable that the animal ligature was known and used by the Egyptian surgeons at a period antedating this wise Jewish philosopher.

The connective tissue of animals was early utilized for a great variety of purposes when it was necessary to secure great strength and high tension. The Homeric poems afford familiar illustrations. In the Odyssey, the strings of the old Greek harp are described as made from the twisted intestine of the sheep. The ancient Egyptian harp is said to have been strung in a similar manner. The celebrated Arabic writer, Rhazes, who practised in Bagdad A.D. 900, describes the stitching of wounds of the abdomen with the strings of the harp, and Albucasis also mentions the stitching together of wounds of the bowel with a fine thread from the twisted intestine of an animal.

The careful student of the early history of surgery finds abundant evidence that the ligature was used as a hæmostatic agent at a very early date. Celsus, at the end of the first century, describes the ligature as of ancient origin, and says that it was used by the Alexandrian school of medicine, with the teachings of which he seems to have been familiar. He advised placing two ligatures upon the vessel and dividing it between the points of tying. Galen recommended its use, and Vesalius, in the sixteenth century, mentions the ligature as a relic of the past, greatly underestimated in value because of the lack of anatomical knowledge. Its first application in amputations, on account of gunshot wounds, was doubtless by Ambrose Paré. At this time wounds were cauterized with boiling oil, in the belief that gunpowder in some way poisoned the wound. Special studies, however, for demonstrating the value of the material used for ligatures do not appear to have been made in the early history of surgery. Indeed, there is little doubt that, whatever the material used, it was always considered as a foreign body to be ultimately eliminated from the wound, and the material, selected for its strength without special reference to the irritation which might be induced thereby, naturally commended itself in the form of thread, silk, or hemp, which was in ordinary domestic use.

To our distinguished countryman, Professor Physick, of the University of Pennsylvania, is undoubtedly due the honor of having first introduced what is first known as the *animal ligature* into surgical practice. His ligatures were made of chamois leather, and he and the late Dr. Dorsey usually rolled their ligatures on a marble slab to make them hard and round. The advantages claimed for the ligatures by Dr. Physick were that, being made of animal matter, they would serve long enough to obliterate the artery and be speedily removed by the absorbents, thus avoiding the difficulty arising from a foreign body, however minute. These ligatures were used in this country to a great extent, and Sir Astley Cooper demonstrated their superiority in his own operations.

Dr. Hartshorn used strips of parchment for his ligatures. My friend, Dr. H. G. Jamieson, Professor of Surgery in Washington Medical College, Baltimore, has for a series of years been employing the animal ligature in an extensive surgical practice. He has used it in many amputations of the limbs and of the mammæ; he has tied the carotid, the iliac, the femoral, the radial, the posterior tibial, the spermatic, and other arteries, with the buckskin ligature, and in no instance had secondary hemorrhage; and he states that he has never seen anything of his ligatures, and, of course, his wounds have generally healed by first intention. Dr. Jamieson gives to Dr. Physick the honor of having first introduced the animal ligature, but he contends that the practice of rolling, or drawing to harden the leather, is highly reprehensible. He advises to tie the artery with a buckskin ligature, very soft and a little broader than the thickness of the skin, taking care not to tie it too tightly. He states, as the result of his observations and experiments upon sheep, dogs, and other animals, that a capsule will surround the ligature, if the capillary vessels be not much disturbed, or the vessel will be surrounded by an abundance of lymph, and the ligature dissolved.

"The method of Ætius and Celsus, revived by Abernethy, of applying two ligatures and dividing the artery between them, Dr. Jamieson condemns as unnecessary, since by a single flat buckskin ligature the artery may be obliterated without destroying its continuity. Hence he opposes all indissoluble ligatures, of whatever material; he declares it not only to be unnecessary, but highly hazardous to cut the inner coats of the vessel, as recommended by Jones, etc.; and agrees with Scarpa as regards flat ligatures; but, by the use of the buckskin, has no need, like him, to remove his ligatures on the fourth day. For a very able and interesting account of his views, which are of the highest practical importance, I would refer to the thirty-seventh number of the *Medical Recorder*, published at Philadelphia, for January, 1827."[1]

The limit of this paper necessitates only brief extracts, although the entire paper is worthy of careful study.

"We believe that the animal ligature will secure the patient from all these dangers except one, to wit, the awkwardness of the surgeon; and even in this respect the animal ligature is preferable, not requiring that precision of management essential to the cutting ligature. If the ligature is cut from the leather with care, it will always admit of being tied sufficiently tight, but can never be made to cut the coats, provided it is made of soft buckskin, and not hardened by drawing it. It is less likely to slip when somewhat insecurely applied, because, being elastic and soft it is spread over a small space of the vessel, and almost immediately adheres by its glutinous properties. It lies more securely, while the cutting ligature, resting on a mere line, and having neither adhesive properties nor the advantage of a small vacuum between the vessel and the ligature, as is the case with the flattish, adhesive ligature, is more likely to slip off. Besides, as we cut off the ends close, there is no risk of pulling them away by an 'accidental jerk of the hand.' In support of these assertions, we have to offer the experience of several years' practice, during which we have used no other than the buckskin ligature, and no such thing as a secondary hemorrhage has ever occurred in our practice, extending alike to cases of aneurism, tumors, and amputations.

"We are, moreover, decidedly of the opinion that in no case whatever have we had reason to suppose that the healing of a wound, accidental or surgical, was delayed by our ligatures; we never see anything of them after their application. . . . Mr. Cooper tied the femoral artery in a female, aged eighty, with a ligature of catgut steeped in water, which was cut close, and the wound was healed on the fourth day, and must, therefore, have healed by first intention.

"In many cases, we believe, the catgut would answer as well as the buckskin, but we are confident that a flat-

[1] Read before the American Association of Obstetricians and Gynecologists, September, 1889.

[1] Cooper's Medical Dictionary, sixth American edition. Edited by D. M. Reese, M.D. Vol. ii., page 130.

tish ligature holds best and is most convenient. It may be proper to mention that this case occurred in 1817, three years after Dr. Physick's use of the leather ligature. . . . If we are right in the opinion which we have just expressed, Dr. Physick is entitled to the credit of bringing into use the best ligature as to the material, but here his claim is at an end. . . . Dr. Physick and Sir Astley Cooper have shown the advantage of using a substance which will serve as a ligature till the artery is obliterated, and be speedily afterward in the power of the absorbents, so that they will remove it. . . . We will now proceed to point out our own views, and endeavor to support them by experiment.

"First. We believe that with an artery sufficiently healthy to admit of its obliteration by the adhesion of its sides, it is best done by a ligature which will neither cut its coats nor strangulate, except in parts, the true *vasa vasorum*, so that the continuity of the vessel shall not be destroyed, although we obliterate its calibre.

"Second. We believe that if an animal ligature of the proper kind be properly applied the vessel will be obliterated, the wound may be healed by first intention, and the ligature will not cause suppurating inflammation; but in due time, being dissoluble, the whole will be removed by the absorbents. There will be no break of continuity in the artery, the *materia arteriarum* will be removed, and the vessel which, during the state of inflammation and the effusion of lymph, was converted into a cord, will pretty soon afterward be resolved to a flat string of white cellular structure.

"*Experiment* 1.—Twenty-two days after tying the carotid artery of a sheep with buckskin ligature the wound was found entirely healed, the artery obliterated, upon one side of which was a little yellowish matter which proved to be a portion of the ligature.

"*Experiment* 2.—Twenty-five days after tying the left carotid of a dog there was seen on either side of the vessel two little yellowish knobs, which proved to be the two ends of the ligature in the state of yellow pulp. The knobs were completely enveloped in a strong membranous capsule, the same capsule enclosing both knobs, and its fibres plainly seen crossing over the artery. . . . On the lower side where the coats were not cut, in splitting open the vessel to examine its interior, there was an actual adhesion of the leather to the inner coat. The string was softened into a pulpy consistence, and near the inside of the vessel was evidently covered with organized lymph, and extended along its edge some distance. When the string was gently pulled, one plainly saw a delicate membrane, passing off from the artery and ending on the string in fringed extremities. This attachment of the vessel by a new formation existed on both sides of the artery. The capsule covering the knobs, or ends of the string, was fully equal in strength to the outer coat of the artery, and therefore there was no tendency to hemorrhage."

It will be seen that in all the essentials the experiments of Dr. Jamieson, undertaken for a similar purpose, were not unlike those of Sir Joseph Lister, repeated half a century later; and the former at a period when so little was expected of the American people in the way of literary productions, to say nothing of scientific research, that one of England's famous critics asked, "Who reads an American book?"

Dr. Ephraim McDowell, in 1809, tied the pedicle of his first case of ovariotomy with a ligature of buckskin.[1]

In the history of ovariotomy in the United States, by the late Dr. Peaslee, it is stated that Dr. Nathan Smith, Professor of Surgery in Yale College, in 1821, tied the arteries with leather ligatures (narrow strips cut from a kid-glove), which were returned into the peritoneal cavity and the incision was closed, followed by recovery.

[1] It is probable that Dr. McDowell, and other operators later, made use of fine strings cut from the skin of the deer which had been tanned after the methods of the Indians, then, and for a long time after, in common use. These gave a ligature greatly superior to that cut from skins tanned by the modern methods.

Dr. John Bellinger,[1] of Charleston, S. C., in 1835, successfully performed ovariotomy, tying two arteries in the pedicle with animal ligatures.

Dr. Thomas Young,[2] of Edinburgh, writes, in 1813: "I have often wished to try ligatures, made of catgut, which might be absorbed." Professor Paul F. Eve,[3] of Nashville, Tenn., wrote, in 1876: "I have been in the habit of using the sinews of the deer for ligating vessels, for forty years. I have never used carbolized spray. The tendons of the deer, dried and torn into shreds, and rolled into ligatures, are what I employ. They are absorbed; I have occasionally used them as sutures, but generally apply silk for this purpose."

These fragmentary experiences, drifting down to us through the years, teach that there was more or less blind groping after a something that should serve a better purpose than that which the routine of daily practice, in the use of the hemp or silken ligature, afforded. It was reserved for the present generation to make possible a scientific basis for the better consideration of ligatures and sutures in their application to the living structures. In the light of our present knowledge of surgical pathology, the opposition to the ligature in the days of Ambrose Paré, which we have been wont to attribute to the conservatism of ignorance and stupidity, is invested with a new and vital interest. The amputated limb, seared with the hot iron, as a hæmostatic, a measure most barbarous and revolting, gave as a result an aseptic wound. Repair was necessarily slow and tedious, but abundant granulation supervened, before decomposition ensued, to protect from septic absorption.

The constricting ligature, the septic, pocketed wound, with little care as to cleanliness, gave such secondary fatal results that we are led to wonder that the innovation of the ligature, in the closing of the great vessels, became the established practice. Had it not been for the frightful dangers from secondary hemorrhage after the use of the cautery, slow healing giving imperfect results, it may well be questioned if even the indomitable spirit of Ambrose Paré could have made the innovation survive his own time.

A deeper philosophy sought solution of the problem, as to the causation of suppuration in wounds, and if its prevention was not within the possibility of the rule, rather than the exception. The studies of Pasteur, Tyndall, our own Jeffries Wyman, and others, undertaken for the solution of the problem of spontaneous generation, brought fruitage to the human race little dreamed of by these wise philosophers.

The genius of Mr. Lister seized upon the application of the thought, and with a patient, investigating spirit, and painstaking toil, worked out the fundamental factors of the rôle of ferments in wounds. It was not until rules could be formulated, based upon the scientific deduction that operative wounds should be free from suppurative processes, hitherto considered almost necessary concomitants, that the proper conditions for the study of ligatures and sutures were rendered possible. Of necessity in intimate association with the question of the treatment of operative wounds arose, *de novo*, a most interesting chapter devoted to the best means of controlling arterial hemorrhage.

It was clear that the hitherto prevailing method of ligation, leaving the ends of the ligature long, extending from the wound, by so much at least prevented primary union; while cutting the ligature short, and closure of the wound, were fraught ever with disastrous consequences, when the septic ferments were thereby deeply buried. When aseptically applied, the constricting silken ligature too often proved an irritating foreign body, to be ultimately slowly eliminated.

In retrospect, with present knowledge, what seems simple factorage of the problem proved extremely difficult

of solution. The conservatism of thought, the prejudices of the large number of the surgical authorities of the time, wedded to present measures, misled by other phases of dominating thought—the so-called vital processes of inflammation, irritation, cell-proliferation, etc.—engrossed the subject with many difficulties. The demonstration that fermentation and suppuration in a wound resulted from the introduction of a *something* from without was the first real step of progress. To eliminate that something was the next problem for solution. It was clearly shown that the torsion of an artery to procure rupture and intrafolding of its interior coat, causes permanent closure of the vessel, and that the living structures, unpoisoned by germ infection, possess the power of easy disposition of the aseptic necrotic portion devitalized by violence.

Histological study demonstrated that the necrosed part no longer underwent the changes which had formerly been supposed necessary for the elimination of dead material, known as suppuration, gangrene, etc., but that the part becomes invaded by living cells which, little by little, produce a local change marked by early disappearance of the necrosed tissue. This naturally led up to the thought, if extraneous animal tissue could not be prepared in a way that, introduced into the vitalized structures, would be followed by a similar result.

Mr. Lister having determined that the safe rule of practice demanded the consideration of every wound, as one primarily infected by the omnipresent atmospheric germ, based as fundamental the principle of the treatment of every wound by agents capable of destroying ferments therein accidentally lodged—the so-called antiseptic method of wound treatment. To this end he found carbolic acid in varying strength of solution eminently advantageous, pursuing his aërial enemies by impregnating the atmosphere immediately about the wound with a carbolic acid solution in fine subdivision, as spray.

Repeated experimentation taught that small pieces of dead tissue, preserved in carbolic acid solutions, incorporated into the living structures, were disposed of in a manner not unlike the necrosed portion of a twisted artery, and led to the inference that animal tissues properly preserved could be used for the constriction of vessels. In looking about for suitable material of animal type to be used as ligature, the catgut prepared for musical purposes naturally offered itself. It proved comparatively easy, by immersion for a considerable period in a carbolic solution, to render the material non-infective, but, as a soft, slippery strand, it lacked necessary qualities in which to make a secure knot, and by its early softening in the tissues, loosened and thereby failed to secure the end sought. A long immersion in an oily solution of carbolic acid, to which a very little water had been added, produced a material change of structure—a kind of tanning process thereby resulted, which gave to the material the quality of less easy softening in the tissues, as well as retaining a firm knot, which was ultimately disposed of by the surrounding structures.

I know of no series of experimental studies better worthy of admiration, or emulation, than Mr. Lister's experiments undertaken for this purpose upon the lower animals, which the laws of England necessitated his resorting to the Continent in order to make possible. The resulting changes, histologically shown to have taken place in ligatures applied to the vessels of the lower animals, examined at different periods, taught that the cell-proliferation at first enclosed, and later on penetrated, the carbolized ligature, until, little by little, it became replaced by living connective-tissue cells—a discovery the importance of which is scarcely fully appreciated, even to the present time. Mr. Lister's experiments were limited to the ligation of vessels, and there has resulted from his teachings the surgical treatment of the great arterial system with a safety hitherto deemed impossible. The larger vessels are now tied in continuity, in close relation to their bifurcations, even the greater trunks, with a seeming impunity little less than startling.

Returning in 1870 from my studies at Edinburgh under Mr. Lister, liberally supplied with a variety of the materials which he then advised in operative treatment, I not only made use of catgut for the ligation of vessels, but accident early furnished me the opportunity for a new application of the ligature, in the form of buried sutures. February 19, 1871,[1] I closed the ring, necessarily greatly enlarged for the reduction of a strangulated hernia, with deep sutures of catgut. This I did in order to retain the abdominal contents, because of the severe asthmatic bronchitis from which the patient was also a sufferer. The resultant permanent cure of the hernia, with a marked proliferation of tissue along the line of the buried sutures, led me to inquire if the sutures buried in the part had not been disposed of in a manner similar to that demonstrated by Mr. Lister, resulting about the catgut ligature surrounding the arteries.

I immediately instituted a series of experimental histological studies upon the lower animals, and demonstrated that, along the track of an aseptically buried suture, cell-proliferation rapidly supervenes, and that new cells invade the softened tissue, and *pari passu* with its absorption, a *living band of connective-tissue cells* replaces the whole line of the suture. If rapidly absorbed, the proliferated cells are minimized; as the process goes on more slowly the change becomes more distinctive, until, in young animals, in ten to fifteen days all trace of the suture as such is lost. The value of such reinforcement of the tissue along the line of the sutures became at once apparent in their application to the cure of hernia, and, little by little, I early extended their use to the closure of wounds of every description, publishing, from time to time, my results.[2]

In the pursuance of my studies, I early had occasion to examine a great variety of the specimens of catgut offered in the market, although from the first I adopted what seemed to me the wise precaution of preparing my own sutures. In catgut, there are, of necessity, certain inherent defects. Its method of preparation is not generally known to the profession, who have rarely questioned the product beyond the condition in which it is offered for sale prepared for the musician. The best of these varieties usually come from Italy, prepared from the intestines of the sheep of the mountainous districts. The small intestine necessarily undergoes maceration until the connective-tissue layer which, as a loose fibrous sheath, unites the mucous and muscular coats of the intestine, is softened, and can be easily separated in a manner not unlike that practised in the preparation of the intestine of the pig for the making of sausages. This is split by a cork, armed with sharp blades, drawn through the circular sheath, dividing it into sections to produce the desired size. These ribbons are twisted, dried, and oftentimes sandpapered to give evenness to surface, and usually put up in little skeins from twelve to fifteen feet in length—the catgut of commerce.

The connective-tissue cells of the fibrous coat of the intestine are irregularly disposed, the fine fibrils more commonly crossing diagonally to the longitudinal axis of the intestine, a wise distribution of this strengthening portion of the intestine to allow considerable change in its shape. When carefully examined, under a low-power lens, the fibres are seen to be irregularly interlaced, not unlike a strip of cloth cut diagonally. The gut, even in the dry state, has a perceptible yield on tension, and every musician knows the care requisite to protect his strings against moisture. Frequent allusion is made in the classics to the care demanded of the bowman in this respect.

[1] A New Use of Carbolized Catgut Ligatures for the Cure of Hernia. Boston Medical and Surgical Journal, November, 1871, vol. viii., page 315.

when it was customary to string the weapon with animal products.

Macerate a piece of catgut until it can be easily unfolded, the above condition is readily apparent. Moreover, its division is rarely uniform, and, when sandpapered the removal of the irregular projections causes oftentimes large abrasions, or rents. No matter how prepared for surgical use, ultimately the result obtained will depend, in considerable measure, upon the integrity of its structure, since the component cells are, little by little, separated by the penetration of the new proliferating tissue. The long maceration in the first stage of preparation, remaining for a considerable time a putrefying mass, necessarily damages the material, not only by softening the adhesion of the cells, but infecting them with bacteria; and in the use of the catgut for all surgical purposes it is important, as the first step in preparation, to destroy any germ infection that may remain. After this has been effected, no method which I have tried gives a result equal to that formulated by Sir Joseph Lister.

"Dissolve one part of chromic acid in four thousand parts of distilled water, and add to the solution two hundred parts of pure carbolic acid, or absolute phenol. In other words, I use a one-to-twenty watery solution of carbolic acid, only that the carbolic acid is dissolved not in pure water, but in an exceedingly dilute solution of chromic acid. But, minute as is the quantity of the chromic acid, it exerts, when in conjunction with carbolic acid, a most powerful effect upon the gut. The first effect of the addition of the carbolic acid to the chromic acid solution is to change its pale yellow color to a rich golden tint. But if the liquid is allowed to stand without the introduction of the catgut, it changes in the course of a few hours to a dingy reddish-brown, and a considerable amount of gray precipitate is formed. If, however, catgut about equal in weight to the carbolic acid is added as soon as the ingredients are mixed, the liquid retains its brightness, and the only change observed is a gradual diminution of the depth of the yellow color; the precipitate, which I presume still occurs, taking place in the substance of the catgut. As soon, therefore, as the preparing liquid has been made, catgut equal in weight to the phenol is introduced into it. If you have too large a proportion of catgut, it will not be sufficiently prepared; if you have too small a quantity, it may run the risk of being over-prepared. At the end of forty-eight hours catgut steeped in such a solution is sufficiently prepared. It is then taken out of the solution and dried, and when dry is placed in one-to-five carbolic oil. It is then fit for use."[1]

It improves by age, and is better not to be used until after it has been several months in carbolic oil. The preliminary disinfection of the gut is of the first importance, since preservation of the hardened structure in the carbolized oil may not penetrate to the destruction of bacteria within the strands.

I have elsewhere published[2] in detail the micrococcal infection developing only along the line of the buried sutures, of four consecutive surgical cases, giving evidence upon which I deduce the conclusion that it could have been only to this inherent defect of the catgut, which had been selected from freshly opened preparations, preserved in carbolic oil, which were sent me from London.

"A great deal of difficulty had been experienced from time to time in the use of catgut, in the formation of stitch abscesses, and the following methods of preparing silk and gut were put to trial: . . .

"The original catgut, as taken from the carbolic oil, was cultured and found to show organisms in every case. . . .

"It is difficult to understand how germs can live that have been immersed in an alcoholic solution of 1 to 1,000 corrosive sublimate, but it is suspected that the hardening of the catgut, prior to complete sterilization, shuts up within the substance of the gut a certain number of organisms, which remain latent until they are placed in living tissues; when the catgut swells the germs are set free, and stitch abscesses result. . . . Reverdin reports a series of experiments in reference to the sterilization of catgut. He found that crude catgut which had not been kept in fat to preserve it, which was exposed for four days to a constantly increasing temperature, maximum 140° C., and then placed for a day in oil of juniper and kept in alcohol, was aseptic. This he had used clinically for eighteen months with perfect results.

"V. Boret has cultured the catgut preserved by Reverdin in bouillon, glycerine, and sugar, at different temperatures, and found that there was no reaction at the end of six weeks. Boret has tried the other methods of sterilizing catgut, and found that, bacteriologically and clinically, they failed. . . .

"*Conclusion.*—Small catgut was found, as ordinarily prepared, to be always sterile; large catgut, never.

"As catgut is too valuable a material to be discarded, the writers would advise the method of Reverdin, by heat, which is bacteriologically a good one."[1]

Dr. Macewen[2] published a very interesting article giving his method of preparing catgut, so as to render it more reliable, by immersing it in a watery solution of chromic acid—1 to 5—and adding one part of this to twenty of glycerine. Remove in two months and preserve ready for use in carbolic acid and glycerine—1 to 5. By varying the strength, gut is prepared possessing different degrees of resistance to absorption in the tissues. My own experience of animal sutures prepared in this way has not been satisfactory.

I have also used catgut prepared in oil of juniper and kept in alcohol, but think it inferior to chromicized gut.

Owing to these inherent defects in catgut, in common with other surgeons, I was led to inquire if there were not other animal tissues better suited for surgical purposes.

The tendinous structures of the body present the connective-tissue cells parallel and firmly united to each other. Although generally thus disposed, there is considerable variety in the arrangement of the cells, making a parallel separation much more uniform in some tendons than in others. As far as possible, a detailed investigation of animal tendons of sufficient size has been prosecuted, with varying success.

The tendons of the hind leg of the moose and caribou, soaked in a sublimate solution until soft, were the first tested. A considerable portion of the tendon may be subdivided sufficiently fine for sutures, in length from fifteen to eighteen inches.

Dr. John H. Gilman,[3] of Lowell, called my attention to tendons from the whale, stating he "had used them with great satisfaction in the ligation of vessels." Specimens were sent me from Provincetown four feet in length and of sufficient strength to draw a cart, but the ultimate fibrils were interlacing, while the whole tendon was interspersed with adipose cells. I obtained ligatures also from the whale tendon which were made under the direction of Dr. T. Ishigure,[4] of Tokio, Surgeon-in-Chief of the Imperial Japanese army. The mode of preparation is given as follows: "First, a whale's tendon is dissected by the points of needles, and teased out until the fibres look very like those of hemp. Secondly, the longest and finest fibres among them are selected, and they are then

[1] In several instances I have known sutures to be ruined by a misunderstanding of the above directions of Mr. Lister, much too large a quantity of chromic acid having been used. It may simplify to remember the quantity is about four grains of chromic acid to a quart of a saturated solution of carbolic acid.

spun together as ordinary silk thread." There can be no question ligatures thus prepared are very serviceable, but the specimens furnished me were not suitable for sutures.

The Sioux Indian women in the Northwest taught me, in 1882, their manner of sewing buffalo skins with the tendinous structures derived from the fascia lata of the buffalo, which they preserve for this purpose by drying and smoking. During the present summer, I obtained from Mr. Harry Adams, of the Hudson Bay Company, in Winnipeg, Manitoba, specimens from the fascia lata of the moose prepared by the Indians of the far Northwest Territories, as a substitute for that from the buffalo now extinct, called by them Astis. They use it in the dry state, stripping it as they sew, occasionally wetting it in the mouth. Good tendon sutures in any quantity can be obtained from this source. My specimens, however, are not more than fifteen inches long, and are quite inferior to the kangaroo tendon. Some years since, a distinguished Russian surgeon sent me similar specimens from the reindeer, finely divided and slightly twisted. These I prepared and used with satisfaction.

In 1880, Dr. S. G. Simmons, of Charleston, S. C., sent me admirable specimens of tendons from the tail of the fox squirrel, with the statement that he had often used them for delicate surgical purposes with great satisfaction. This tendon is composed of exquisitely beautiful parallel fibrils, which can be subdivided, without fraying, to the size of fine threads. Their extreme length, however, scarcely exceeds nine inches. Reasoning from comparative studies, it seemed to me highly probable that the kangaroo should possess a tendon, similar in quality, traversing the entire length of the tail. Through the kindness of the late Mr. Alonzo H. Newell, of Boston, for many years a prominent merchant in Australia, I obtained some most excellent specimens. At the International Medical Congress held in London, in 1881, in a paper [1] upon the cure of hernia, I mentioned the use of the tendon suture from the kangaroo and other animals, as especially to be commended. Reference to my recommendation of the kangaroo tendon and its value in surgery, was some time later made in an Australian publication. This came to the notice of Dr. Girdlestone, who wrote me that he had used kangaroo tendons for some years with great satisfaction, and had published the results.[2]

The tendons should be taken from recently killed animals, quickly sun-dried, and kept dry until ready for further preparation. This prevents primary decomposition, which we have pointed out as necessary in the preparation of the catgut. When soaked until soft they are easily separated as fine as desired, with remarkably little waste, and give threads from the size of hairs upward, and from eighteen inches to two feet in length, exceptional specimens being even considerably longer. The kangaroos are so numerous as to make their skins of commercial value, being sent to the United States in lots each of many thousands, yet it is only with the greatest difficulty and expense that I have succeeded in securing tendons sufficient for my own use, although I have sent *carte blanche* orders to various parties in Australia. I was informed they could be obtained in London, but two years ago the enterprising firm of Grosvenor & Richards, of Boston, searched the London markets without avail. Quite recently, Felton, Grimwalde & Co., of Melbourne, Australia, wrote me that they regularly keep in stock tendons prepared for surgical purposes. I cannot doubt that, at an early date, surgeons will be furnished with the kangaroo tendons, which I fully believe are in every way greatly to be preferred to catgut.

In an interesting article published in 1882 by Dr. Girdlestone,[3] he emphasizes the use of the tendon entire as a ligature rather than suture. "In their preparation they should not be removed from the tail *en masse*, but one at a time, without force, as if split longitudinally they could not be relied on. Every diameter that was required was attainable, so that there was no occasion for splitting; neither should two or more tendons be twisted together, as it destroys their flattened form." The advantage claimed is, that they may be used as flat rather than round ligatures, constricting the artery with less liability of cutting the vessel.

Dr. Dudley,[1] of Texas, has written a most interesting article upon the use of the tendon of the lepus, or muleeared rabbit, as a material for ligatures and sutures. Dr. Dudley does not state the portion of the animal from which he obtains the tendon, but describes them as, "an aponeurosis of muscles rolled upon each other, susceptible of being torn into minute threads, if so desired." He first had occasion to use the tendon of the lepus as a suture, in the fresh state, in 1881, finding he had no silk in his pocket-case. He has continued the use of these tendons with the greatest satisfaction to the time of his report.

Dr. Bernes [2] published an interesting study upon animal ligatures in 1874. Although his experiments were not conducted with the care demanded to-day, yet they are still of interest and importance as original studies. They include a large number of experiments upon the lower animals with gut, both carbolized and uncarbolized, peritoneum cut into strips and rolled, as recommended by Dr. Agnew, and beef tendon dried, split into fine shreds and twisted, as well as silk, which was used as a standard of comparison.

"The extreme non-irritating properties of the tendon, coupled with its capacity for fine division, render its slow absorption of decided advantage, since a vessel can be secured with a strand of it so fine as to produce no irritation, and yet sufficient time elapse before its disappearance to render any danger from secondary hemorrhage as remote as in the employment of silk, by which the vessel is usually severed in the course of a very few days. . . . It will be seen that the tendon ligature fulfils all the requirements set down at the beginning of this paper for a substitute for the material now in use. . . . It is, beyond all doubt, ultimately absorbable, so that a ligature of it can be cut off close to the knot and left in the wound. The tendon is by no means so absorbable as catgut."

The use of animal suture requires the same and the only precautions that are requisite to the successful application of the ligature. It *must be* in *itself aseptic;* it must be *aseptically applied* in an *aseptic wound*. When thus applied, the range of its uses may be extended to all operative wounds. It is difficult to conceive of any possible advantage to be derived in the treatment of any aseptic wound by leaving it open—the so-called open-wound method.

Before the rôle of bacteria in wounds was understood, when it befell from chance, rather than scientific care, that primary union supervened, it is easy to understand how many who dreaded the daily experiences of fermentative material retained in pocketed wounds not only refused to rely upon drainage with occasional irrigation, as a sufficient preventive of septic poisoning, but they insisted, as far as possible, upon allowing no recess in which purulent material could gather. In order to effect this, the lips of the wound were separated and kept apart by antiseptic dressings, so that the wound might heal by granulation from its very base. This is manifestly safer for the patient, and the result attained is not unlike that from the repair processes which supervene in the secondary healing of infected wounds; but those who advocate this method thereby confessedly acknowledge their lack

of confidence in the modern methods of wound treatment, and their inability to protect wounds from infection.

In rare instances it has been claimed that the resulting citatricial union gives an increased strength to the parts involved, an opinion which it seems easy to show is unscientific and contrary to the general consensus of surgical opinion.

If it is correct to assume that the theoretic perfection in wound-treatment, which it is the ambition of the surgeon to attain, means a reunion of the divided parts, the anatomical relationship to be restored and maintained, then the suture holds a higher place in surgery than ever hitherto considered.

If the suture itself is replaced by vitalized structures, then its proper application becomes of the highest importance, the value of which the profession is only recently seeming to begin to realize. Given, as illustration, the joining of a divided retracted nerve, or muscle, and its restoration to subsequent perfect usefulness; the sundered cervical tissues after a hysterectomy, where the delicate joining of the peritoneum allows no open wound for hemorrhage or absorption; the reunion of the abdominal wound after laparotomy, where the peritoneum is independently united by a layer of buried sutures, and where the linea alba, or the muscular aponeurosis of the sheath of the recti is carefully rejoined, since the adoption of which method I have not had a single case of ventral hernia; or, again, in the amputation of large tumors of the breast, where the remaining tissues are carefully coapted, so that retention and pocketing of fluid are impossible, rendering drainage not only superfluous but harmful.

I would not underestimate the importance of drainage in wounds that are necessarily septic, and in this class of wounds there is no advantage to be gained in the attempted use of the buried suture.

The recent discussions upon the uses and advantages of the buried animal suture are both interesting and profitable. A valuable article, based upon original observations, was published in Germany by Dr. Werth,[1] in which he advocates the use of catgut, in the repair of the perinæum, as an interrupted buried stitch. These were taken between one and two centimetres apart, the gut tied and cut short upon the knot. In cases where the surfaces to be coapted were large, a second row of stitches was similarly placed. Great care was exercised in making the application under aseptic precautions, and most satisfactory results were obtained.

Schroeder[2] repeatedly used catgut as a buried continuous suture, and commended it highly. Dr. A. Martin[3] is less enthusiastic, and says: "I, myself, have tried catgut sutures according to Werth five times; the results were not favorable, but I must admit that in two of these cases the catgut may have been too old."

Doléris[4] recommended knotting the thread, from time to time, of the continuous suture, and believes the buried gut is absorbed in seven or eight days. He reported to me when in America, in 1887, a still further satisfactory use of buried animal sutures.

Bröse[5] writes approvingly of buried catgut sutures rendered aseptic by a corrosive sublimate solution and preserved in absolute alcohol.

Dr. C. B. Keetley[6] published a valuable article upon the uses of the buried suture. He ascribes to Professor Esmarch's assistant, Neuber, and Professor Küster, much valuable original work with the use of the buried suture, especially in amputations, thereby doing away with drainage. He writes: "Küster read his paper at the last meeting of the Society of German Surgeons. In the discussion that followed, Esmarch having stated that, with these sunk sutures, drainage-tubes could be altogether dispensed with, he was asked, 'What, after excision of the hip?' He thereupon answered shortly and decisively, 'Yes.'"

In conclusion, he says: "I have to say that it is only in strictly antiseptic surgery I would venture to recommend the use of these sutures, but that in the case of all surgeons who have faith in the antiseptic theory and practice, they will find in buried sutures an effective and beautiful addition to their methods."

Mr. John Wood[7] writes in regard to femoral hernia:

"Latterly, I have found the use of tendon ligature so satisfactory, that for this operation I prefer it to wire. The wound usually closes over it and heals by adhesion at once, and there is not the pain and inconvenience of the withdrawal of the wire. So far the endurance of the tendon, when buried in the tissues, has been long and satisfactory enough to maintain the cure, which has been watched, noted in some cases about two years."

My own experience with the buried animal suture commenced with its use in the case of hernia above referred to, in 1871, and this, with other cases where the cure was believed to be referable to the buried suture, was first published in the *Boston Meaical and Surgical Journal*, November, 1871. In 1878 I contributed a paper on the subject at the meeting of the American Medical Association. In 1881 a further contribution upon the same subject, emphasizing the value of the tendon suture, was published in the "Transactions of the International Medical Congress."

These and various other articles, giving the results and surgical advantages of the use of the buried animal suture and its adaptability to special purposes, were reprinted and widely distributed to the profession, both in Europe and America.[8]

If the premises which I have assumed in the early discussion of this paper are correct—that a properly prepared aseptic animal suture, aseptically applied, retains its strength sufficiently long to hold at rest the coapted parts until primary union is effected, and then itself slowly disappears, after having fulfilled this function, to be in a measure replaced by vitalized connective tissue—there can be little wanting to attain the theoretic perfection in the suturing of wounds. The first observations which I published, perhaps naturally, provoked only incredulity, and the results were considered at best accidental. The evidence already accumulated and presented to the profession, by a great variety of observers in different parts of the civilized world, is now sufficient to substantiate this claim.

Silk has justly held a high place in the esteem of the profession because of its exquisite perfection of preparation, and it has been claimed, if rendered aseptic, that it was equally safe as a buried suture. Mr. Lawrence,[9] the distinguished English surgeon, made many interesting and valuable studies upon the ligation of vessels with silk cut short and buried in the wound. His efforts to minimize what he considered the irritating foreign material are very instructive:

"The method I have adopted consists in tying the vessels *with fine silk ligatures* and cutting off the ends as close to the knot as is consistent with its security. . . .

Of the silk which I commonly employ, a portion sufficient to tie a large artery, when the ends are cut off, weighs between one-fiftieth and one-sixtieth of a grain."

He adds: "Although I have not yet ascertained what becomes of the pieces of ligature after the wound is united, I have never seen abscesses or any other bad symptom occasioned by them."

Mr. Lister early experimented very carefully with silk, steeped in various substances, immersed in melted wax and carbolic acid to render it aseptic. In further proof of its innocuousness, it has been claimed that it is also an animal product, and that the tissues should be capable of assimilating it into their own structures. My distinguished friend, Dr. Pancoast, of Philadelphia, believes the fault lies, in large measure, in the introduction of lead during its preparation, and that hence the use of iron-dyed silk is greatly to be preferred:

"It is innocuous, does not produce suppuration along the track of its thread, and the color adds much to the ease with which it may be distinguished for its removal."

Advantages, doubtless, but the necessity of removal emphasizes the fault in material, and not in the color or the skill of application, which renders it manifestly unfitted for use as a buried suture.

The general verdict of surgical opinion, and it has certainly been often repeated in my own experience, is that aseptic silk, aseptically applied, may be incorporated into the tissues, but remains encysted, and often, after a considerable lapse of time, causes irritation and is expelled as a foreign body.[1]

The mode of application of the buried suture is of the greatest importance. Without exception it should be a continuous suture, since thus used more perfect coaptation of the parts can be obtained, while, as far as possible, knots should be avoided. It is important to minimize the material consistent with careful coaptation. It should join like tissues, periosteum to periosteum, muscle to muscle, deep fascia to deep fascia, and skin to skin, after deep incisions of all kinds. It should support the parts always without any constriction of tissue. Having secured these ends, it matters comparatively little by what manner of stitch it is applied. The opinions of operators will be modified in preference for the methods to which they have become accustomed.

For certain purposes it has seemed to me a manifest gain to include the tissues by a double suture, taken by means of a needle with eye near the point, which allows the ends of the suture to be introduced through the same puncture from opposite directions. This of necessity encloses, and should coapt, but *must not constrict*, the tissues involved. The advantages of this stitch are most apparent in certain operations, and I have especially advocated its use in the closure of the canal in hernia, in suturing the pedicle of uterine and ovarian tumors, and in perineorrhaphy.

For wounds in the intestine, and in resection, I have repeatedly used a double layer of tendon sutures, the Lembert stitch, taken as a continuous, not an interrupted, suture. The finer curved Hagedorn needles are the best. The needle pierces the peritoneum as in the Lembert stitch, entering and emerging about two lines from the sides of the wound. This intrafolds and coapts the peritoneum evenly. In resection of the intestine, or if an incised wound is long, I take a second layer about one-fourth of an inch outside of the first, coapting more peritoneum and thereby burying entirely the first line of sutures. Post-mortem intestine thus joined will hold water, and in a well-vitalized subject the effused lymph, in a few hours, entirely covers in the affected part. The advantages of this method are simplicity, rapidity of operation, avoidance of knots, a minimum of manipulation and of injury of the tissues involved, even and sure closure of the parts—all of which are of the first importance to a good result, as well as to the security and non-irritability of the tendon suture.

As far as possible, the sutures should cross the wound at right or acute angles and not lie parallel with it. For the coaptation of large wounds, as in amputation of the breast, I have found it a decided advantage to use a running stitch, taken from side to side, both ends left externally free, tension upon which evenly coapts the sides of the wound. Fine tendons are thus introduced in two, three, or more layers, commencing at the very base of the wound.

The skin is evenly coapted by a blind running stitch taken from within outward through the deeper layer only. This evenly unites the edges of the skin, while the suture itself is buried beneath it. The wound is dried, dusted with iodoform, and covered with a layer of iodoform collodion, reinforced by a few fibres of absorbent cotton. The ends of the deep lines of the running sutures, after sufficient tension has been exercised to produce coaptation, are fixed in the collodion and cut off.

The subsequent dressing matters little; a soft pad of cotton may give comfort by its support, but if the wound is *aseptic* at the close of the application of the iodoform collodion, it being presupposed that each step has been taken with modern aseptic precautions, *primary union will supervene, and drainage is not only needless, but is a positive disadvantage and danger.*

Aseptic wounds thus treated give really a simplicity of detail which seems surprising when contrasted with the clumsy and bungling antiseptic dressings which this method—the aseptic application of buried animal sutures—is destined to supersede. In conclusion, the rôle of the buried animal suture may be accepted as a corollary to antiseptic surgery, upon the basic principles of which it is founded as a scientific deduction.

CASE OF PAPILLOMA OF LARYNX CURED BY INTUBATION.

By J. F. BALDWIN, M.D.,

COLUMBUS, O.

JUNE 30, 1889, Albert C——, aged eight years, was brought to my office from Jersey, O., having been referred to me by the family physician, Dr. J. T. Mills. His history was given as follows: Until the age of two years he was as healthy as other children. At that time he was affected with scarlet fever, during convalescence from which it was noticed that he was hoarse and could only speak in a whisper. This was supposed to be due to a partial paralysis of the vocal cords, and a favorable prognosis given. But these symptoms did not abate, and after some months there was decided dyspnœa. A physician of this city was then consulted, who made a laryngoscopic examination, pronounced the trouble tuberculous, and sent the child home to die. The dyspnœa was at this time extreme, the child breathing like one affected with croup. He was kept confined to the house for weeks at a time during inclement weather, and never allowed to be out in the evening air, as the slightest laryngitis, the result of exposure, would cause an exacerbation of the dyspnœa. Repeatedly, during these attacks, his life was despaired of, and on one occasion Dr. Mills undoubtedly saved him by passing a rubber catheter into the larynx. His breathing during these years was rapid, and his pulse was never less than 120. He was greatly emaciated and anæmic; could take no active exercise, and could talk only in a whisper.

I found him in the condition indicated above. His weight was thirty-one pounds. On making a laryngoscopic examination, I found a large papilloma attached by a rather broad base to the edge and upper surface of the left vocal cord, and to the anterior angle between the cords. The tumor was rather soft. During inspiration it would flap across the chink, obstructing it momentarily; then, as the inspiratory effort increased, would be sucked below the cords, allowing the air to enter. During ex-

piration this action was reversed. This to-and-fro flapping could be distinctly heard as well as seen. Dr. Clarence Maris, who had studied under Morell Mackenzie, saw the case with me, and said the tumor was the largest he had ever seen.

As his breathing was very labored at this visit, and he had not come prepared to remain in the city, I inserted an O'Dwyer tube and sent him home. He returned July 3, breathing much easier, although he had coughed the tube out the day after its insertion. The tumor was evidently smaller, as viewed with the laryngoscope, so much so that I remarked to those present that if its removal by means of laryngeal forceps failed, I should try the effect of persistent intubation before performing laryngotomy.

The parts about the larynx were unusually sensitive, the slightest contact of any foreign body causing spasmodic closure of the larynx. This sensitiveness was not relieved in the least by the long-continued use of a strong solution of cocaine, so that I was compelled to use chloroform. Under this I was able to seize and remove a small piece of the growth, but not enough to give any relief. Drs. Nash and Wright were assisting me, and we decided that the boy was too weak to bear prolonged anæsthesia.

On July 4, the use of the tube was again resorted to, with the determination to give it a fair trial. On the 9th, I commenced the use of the largest tube in the case, in order to get more pressure. The case was peculiar in that it was impossible for the patient to swallow the least
